C. G. JUNG

SECOND EDITION

TRANSLATED BY R. F. C. HULL

BOLLINGEN SERIES XX

PRINCETON UNIVERSITY PRESS

Second printing, 1975

Third printing, 1978, with corrections and an addition (*see page 88*)

First Princeton / Bollingen Paperback printing, 1983

THIS EDITION IS BEING PUBLISHED IN THE UNITED STATES OF AMERICA BY PRINCETON UNIVERSITY PRESS AND IN ENGLAND BY ROUTLEDGE AND KEGAN PAUL, LTD. IN THE AMERICAN EDITION, ALL THE VOLUMES COMPRISING THE COLLECTED WORKS CONSTITUTE NUMBER XX IN BOLLINGEN SERIES, SPONSORED BY BOLLINGEN FOUNDATION. THE PRESENT VOLUME IS NUMBER 1 OF THE COLLECTED WORKS, AND WAS THE SIXTH TO APPEAR.

LIBRARY OF CONGRESS CATALOG CARD NUMBER: 75–156
ISBN 0-691-09768-2
ISBN 0-691-01855-3 pbk.
MANUFACTURED IN THE U. S. A.

EDITORIAL PREFACE

The publication of the first complete collected edition, in English, of the works of C. G. Jung is a joint endeavour by Routledge and Kegan Paul, Ltd., in England and, under the sponsorship of Bollingen Foundation, by Princeton University Press in the United States. The edition contains revised versions of works previously published, such as *The Psychology of the Unconscious,* which is now entitled *Symbols of Transformation;* works originally written in English, such as *Psychology and Religion;* works not previously translated, such as *Aion;* and, in general, new translations of the major body of Professor Jung's writings. The author has supervised the textual revision, which in some cases is extensive.

In presenting the Collected Works of C. G. Jung to the public, the Editors believe that the plan of the edition * may require a short explanation.

The editorial problem of arrangement was difficult for a variety of reasons, but perhaps most of all because of the author's unusual literary productivity: Jung has not only written several new books and essays since the Collected Works were planned, but he has frequently published expanded versions of texts to which a certain space had already been allotted. The Editors soon found that the original framework was being subjected to severe stresses and strains; and indeed, it eventually was almost twisted out of shape. They still believe, however, that the programme adopted at the outset, based on the principles to be outlined below, is the best they can devise.

An arrangement of material by strict chronology, though far the easier, would have produced a rather confusing network of subjects: essays on psychiatry mixed in with studies of religion, of alchemy, of child psychology. Yet an arrangement according to subject-matter alone would tend to obscure a view of the progress of Jung's researches. The growth of his work, however, has made a combination of these two schemes possible, for the unfolding of Jung’s psychological concepts corresponds, by and large, with the development of his interests.

C. C. Jung was born in northeastern Switzerland in 1875, a Protestant clergyman’s son. As a young man of scientific and philosophical bent, he first contemplated archaeology as a career, but eventually chose medicine, and qualified with distinction in 1900. Up to this time, Jung had expected to make physiological chemistry his special field, in which a brilliant future could be expected for him; but, to the surprise of his teachers and contemporaries, he unexpectedly changed his aim. This came about through his reading of Krafft-Ebing’s famous *Text-Book of Insanity*, which caught his interest and stimulated in him a strong desire to understand the strange phenomena he there found described. Jung’s inner prompting was supported by propitious outer circumstances: Dr. Eugen Bleuler was then director of the Burghölzli Mental Hospital, in Zurich, and it was under his guidance that Jung embarked on his now well-known researches in psychiatry.

The present volume, first of the Collected Works, though not large, is sufficient to contain the studies in descriptive psychiatry. It opens with Jung’s first published work, his dissertation for the medical degree: “On the Psychology and Pathology of So-called Occult Phenomena” (1902), a study that adumbrates very much of his later work. But clearly a man of Jung’s cast of mind could not be content with simple descriptive research, and soon he embarked upon the application of experimental psychology to psychiatry. The copious results of these researches make up Volume 2 and Volume 3. Jung’s work brought about the transformation of psychiatry, as the study of the psychoses, from a static system of classification into a dynamic interpretative science. His monograph “The Psychology of Dementia Praecox” (1907), in Volume 3, marks the peak of this stage of his activity.

It was these experimental researches that led Jung to a fruitful if stormy period of collaboration with Freud, which is represented by the psychoanalytic papers in Volume 4. The chief work in this volume, “The Theory of Psychoanalysis” (1913), gives at length his first critical estimation of psychoanalysis. Volume 5, *Symbols of Transformation* (originally 1912), and Volume 7, *Two Essays on Analytical Psychology* (originally 1912 and 1916), restate his critical position but also make new contributions to the foundation of analytical psychology as a system.

The constant growth of analytical psychology is reflected in Jung's frequent revision of his publications. The first of the *Two Essays on Analytical Psychology*, for example, has passed through several different editions. *Psychology of the Unconscious*, as it was titled in its first (1916) edition in English, appears in the Collected Works, extensively revised by Jung, with the title *Symbols of Transformation*. The Editors decided to leave these works in the approximate chronological positions dictated by the dates of their first editions, though both are published in revised form. Revision and expansion also characterize the group of studies that form Volume 12, *Psychology and Alchemy* (originally 1935–36), as well as many single essays in other volumes of the present edition.

Psychological Types (Volume 6), first published in 1921, has remained practically unchanged; it marks the terminus of Jung's move away from psychoanalysis. No further long single work appeared till 1946. During the intervening period, when Jung's professional work and his teaching occupied a large part of his time, he was abstracting, refining, and elaborating his basic theses in a series of shorter essays, some of which are collected in Volume 8, *The Structure and Dynamics of the Psyche*.

Volume 9, part I, contains essays, mostly of the same period, that have special reference to the collective unconscious and the archetypes. Part II of this volume, however, contains a late (1951) major work, *Aion: Researches into the Phenomenology of the Self*. From the chronological point of view, *Aion* should come much later in this sequence, but it has been placed here because it is concerned with the archetype of the self.

From Volume 10 onwards, the material deals with the application of Jung's fundamental concepts, which, with their historical antecedents, can be said by now to have been adequately set out. The subject-matter of Volume 10 to Volume 17—organized, in the main, around several themes, such as religion, society, psychotherapy, and education—is indicated by the volume titles and contents. It will be noted that, in his later years, Jung has returned to writing longer works: *Aion*, the *Mysterium Coniunctionis*, and perhaps others yet to come from his pen. These arise, no doubt, out of the reflective stage of his life, when retirement from his analytical practice has at last given him time to work out ideas that those who know him have long wanted to see in print.

In 1956, Professor Jung announced that he would make available to the Editors of the Collected Works two accessions of material which will have the effect of enhancing and rounding out the edition: first, a selection of his correspondence on scientific subjects (including certain of his letters to Freud); and second, the texts of a number of the seminars conducted by Jung. Accordingly, Volume 18, and thereafter such additional volumes as may be needed, will be devoted to this material.

The Editors have set aside a final volume for minor essays, reviews, newspaper articles, and the like. These may make a rather short volume. If this should be so, an index of the complete works and a bibliography of Jung's writings in original and in translation will be combined with them; otherwise, the index and bibliography will be published separately.

*

In the treatment of the text, the Editors have sought to present Jung's most recent version of each work, but reference is made where necessary to previous editions. In cases where Professor Jung has authorized or himself made revisions in the English text, this is stated.

In a body of work covering more than half a century, it cannot be expected that the terminology would be standardized; indeed, some technical terms used by Jung in an earlier period were later replaced by others or put to different use. In view of their historical interest, such terms are translated faithfully according to the period to which they belong, except where Professor Jung has himself altered them in the course of his revision. Occasionally, editorial comment is made on terms of particular interest. The volumes are provided with bibliographies and are fully indexed.

*

Of the contents of Volume 1, nothing has previously been translated into English except the monograph "On the Psychology and Pathology of So-called Occult Phenomena." The translation of the latter by M. D. Eder has been consulted, but in the main the present translation is new. It may be noted that, except for the 1916 English version of the “Occult Phenomena,” none of these papers has ever been republished by Professor Jung.

An effort has been made to fill out the bibliographical details of the material, which were sometimes abbreviated in the medical publications of the 1900’s.

Acknowledgment is made to George Allen and Unwin Ltd. for permission to quote passages from Freud’s *The Interpretation of Dreams* and from Nietzsche’s *Thus Spake Zarathustra*.

EDITORIAL NOTE TO THE SECOND EDITION

Since the above paragraphs were written, and following Jung’s death on June 6, 1961, different arrangements for the publication of the correspondence and seminars have been made with the consent of his heirs. These writings will not, as originally stated, comprise Volume 18 and subsequent volumes of the Collected Works (for their contents as now planned, see below). Instead, a large selection of the correspondence, not restricted to scientific subjects though including some letters to Freud, will be issued under the same publishing auspices but outside the Collected Works, under the editorship of Dr. Gerhard Adler. A selection of the seminars, mainly those delivered in English between 1925 and 1939, will also be published outside the Collected Works in several volumes.

Two works usually described as seminars are, however, being published in the Collected Works, inasmuch as the transcripts were approved by Jung personally as giving a valid account of his statements: the work widely known as the Tavistock Lectures, delivered in London in 1935, privately circulated in multigraphed form, and published as a separate volume entitled *Analytical Psychology: Its Theory and Practice* (Routledge & Kegan Paul, London, and Pantheon Books, New York, 1968); and the seminar given in 1938 to members of the Guild of Pastoral Psychology, London, and published in pamphlet form by the Guild in 1954 under the title *The Symbolic Life*. Both of these will be published in Volume 18, which has been given the general title *The Symbolic Life*.

Volume 18 will also include the minor essays, reviews, forewords, newspaper articles, and so on, for which a “final volume” had been set aside. Furthermore, the amount of new material that has come to light since the Collected Works were planned is very considerable, most of it having been discovered after Jung’s death and too late to have been placed in the volumes where thematically it belonged. The Editors have therefore assigned the new and posthumous material also to Volume 18, which will be much larger than was first envisaged. The index of the complete works and a bibliography of Jung's writings in the original and in translation will be published as two separate and final volumes.

Jung ended his long years of creative activity with the posthumously published *Memories, Dreams, Reflections*, recorded and edited by Aniela Jaffé and translated by Richard and Clara Winston (Collins with Routledge & Kegan Paul, London, and Pantheon Books, New York, 1963). At his express wish it was not included in the Collected Works.

*

Finally, the Editors and those closely concerned with implementing the publication programme, including the translator, wish to express their deep sense of loss at the death of their colleague and friend, Sir Herbert Read, who died on June 12, 1968.

*

For the second edition of *Psychiatric Studies*, bibliographical citations and entries have been revised in the light of subsequent publications in the Collected Works and essential corrections have been made.

*

In 1970, the Freud and Jung families reached an agreement that resulted in the publication of *The Freud/Jung Letters* (the complete surviving correspondence of 360 letters), under the editorship of William McGuire, in 1974. And a selection from all of Jung's correspondence throughout his career, edited by Gerhard Adler in collaboration with Aniela Jaffé, was published in 1973 (1906–1950) and 1975 (1951–1961). Finally, a selection of interviews with Jung was published in 1977 under the title C. G. *Jung Speaking: Interviews and Encounters*.

VOLUME 1
PSYCHIATRIC STUDIES

TABLE OF CONTENTS

I

On the Psychology and Pathology of So-called Occult Phenomena

Translated from *Zur Psychologie und Pathologie sogenannter occulter Phänomene* (Leipzig, 1902).

On Hysterical Misreading

Translated from “Über hysterisches Verlesen,” *Archiv für die gesamte Psychologie* (Leipzig), III (1904).

II

Cryptomnesia

Translated from “Kryptomnesie,” *Die Zukunft* (Berlin), 13th year (1905), L.

III

On Manic Mood Disorder

Translated from “Über manische Verstimmung,” *Allgemeine Zeitschrift für Psychiatrie und psychisch-gerichtliche Medizin* (Berlin), LXI (1903).

IV

A Case of Hysterical Stupor in a Prisoner in Detention

Translated from “Ein Fall von hysterischem Stupor bei einer Untersuchungsgefangenen,” *Journal für Psychologie und Neurologie* (Leipzig), I (1902).

V

On Simulated Insanity

Translated from “Über Simulation von Geistesstörung,” *Journal für Psychologie und Neurologie* (Leipzig), II (1903).

A Medical Opinion on a Case of Simulated Insanity

Translated from “Ärztliches Gutachten über einen Fall von simulierter geistiger Störung,” *Schweizerische Zeitung für Strafrecht* (Zurich), XVII (1904).

VI

A Third and Final Opinion on Two Contradictory Psychiatric Diagnoses

Translated from “Obergutachten über zwei sich widersprechende psychiatrische Gutachten,” *Monatsschrift für Kriminalpsychologie und Strafrechtsreform* (Heidelberg), II (1906).

On the Psychological Diagnosis of Facts

Translated from “Zur psychologischen Tatbestandsdiagnostik,” *Zentralblatt für Nervenheilkunde und Psychiatrie* (Leipzig), XXVIII (1905).

I

ON THE PSYCHOLOGY AND PATHOLOGY OF SO-CALLED OCCULT PHENOMENA

ON HYSTERICAL MISREADING

ON THE PSYCHOLOGY AND PATHOLOGY OF SO-CALLED OCCULT PHENOMENA[1]

[1. INTRODUCTION]

[1] In that wide domain of psychopathic inferiority from which science has marked off the clinical pictures of epilepsy, hysteria, and neurasthenia, we find scattered observations on certain rare states of consciousness as to whose meaning the authors are not yet agreed. These observations crop up sporadically in the literature on narcolepsy, lethargy, *automatisme ambulatoire*, periodic amnesia, double consciousness, somnambulism, pathological dreaminess, pathological lying, etc.

[2] The above-mentioned states are sometimes attributed to epilepsy, sometimes to hysteria, sometimes to exhaustion of the nervous system–neurasthenia–and sometimes they may even be accorded the dignity of a disease *sui generis*. The patients concerned occasionally go through the whole gamut of diagnoses from epilepsy to hysteria and simulated insanity.

[3] It is, in fact, exceedingly difficult, and sometimes impossible, to distinguish these states from the various types of neurosis, but on the other hand certain features point beyond pathological inferiority to something more than a merely analogical relationship with the phenomena of normal psychology, and even with the psychology of the supranormal, that of genius.

[4] However varied the individual phenomena may be in themselves, there is certainly no case that cannot be related by means of some intermediate case to others that are typical. This relationship extends deep into the clinical pictures of hysteria and epilepsy. Recently it has even been suggested that there is no definite borderline between epilepsy and hysteria, and that a difference becomes apparent only in extreme cases.

Steffens, for example, says: “We are forced to the conclusion that in essence hysteria and epilepsy are not fundamentally different, that the cause of the disease is the same, only it manifests itself in different forms and in different degrees of intensity and duration.”[2]

[5] The delimitation of hysteria and certain borderline forms of epilepsy from congenital or acquired psychopathic inferiority likewise presents great difficulties. The symptoms overlap at every point, so that violence is done to the facts if they are regarded separately as belonging to this or that particular group. To delimit psychopathic inferiority from the normal is an absolutely impossible task, for the difference is always only “more” or “less.” Classification in the field of inferiority itself meets with the same difficulties. At best, one can only single out certain groups which crystallize round a nucleus with specially marked typical features. If we disregard the two large groups of intellectual and emotional inferiority, we are left with those which are coloured pre-eminently by hysterical, epileptic (epileptoid), or neurasthenic symptoms, and which are not characterized by an inferiority either of intellect or of emotion. It is chiefly in this field, insusceptible of any sure classification, that the above-mentioned states are to be found. As is well known, they can appear as partial manifestations of a typical epilepsy or hysteria, or can exist separately as psychopathic inferiorities, in which case the qualification “epileptic” or “hysterical” is often due to relatively unimportant subsidiary symptoms. Thus somnambulism is usually classed among the hysterical illnesses because it is sometimes a partial manifestation of severe hysteria, or because it may be accompanied by milder so-called “hysterical” symptoms. Binet says: “Somnambulism is not one particular and unchanging nervous condition; there are many somnambulisms.”[3] As a partial manifestation of severe hysteria, somnambulism is not an unknown phenomenon, but as a separate pathological entity, a disease *sui generis*, it must be somewhat rare, to judge by the paucity of German literature on this subject. So-called spontaneous somnambulism based on a slightly hysterical psychopathic inferiority is not very common, and it is worth while to examine such cases more closely, as they sometimes afford us a wealth of interesting observations.

[6] CASE OF MISS E., aged 40, single, book-keeper in a large business. No hereditary taint, except that a brother suffered from “nerves” after a family misfortune and illness. Good education, of a cheerful disposition, not able to save money; “always had some big idea in my head.” She was very kind-hearted and gentle, did a great deal for her parents, who were living in modest circumstances, and for strangers. Nevertheless she was not happy because she felt she was misunderstood. She had always enjoyed good health till a few years ago, when she said she was treated for dilatation of the stomach and tapeworm. During this illness her hair turned rapidly white. Later she had typhoid. An engagement was terminated by the death of her fiancé from paralysis. She was in a highly nervous state for a year and a half. In the summer of 1897 she went away for a change of air and hydrotherapy. She herself said that for about a year there were moments in her work when her thoughts seemed to stand still, though she did not fall asleep. She made no mistakes in her accounts, however. In the street she often went to the wrong place and then suddenly realized that she was not in the right street. She had no giddiness or fainting-fits. Formerly menstruation occurred regularly every four weeks with no bother; latterly, since she was nervous and overworked, every fourteen days. For a long time she suffered from constant headache. As accountant and book-keeper in a large business she had a very strenuous job, which she did well and conscientiously. In the present year, in addition to the strains of her work, she had all sorts of new worries. Her brother suddenly got divorced, and besides her own work she looked after his housekeeping, nursed him and his child through a serious illness, and so on. To recuperate, she went on September 13 to see a woman friend in southern Germany. Her great joy at seeing her friend again after such a long absence, and their celebration of a party, made the necessary rest impossible. On the 15th, quite contrary to her usual habit, she and her friend drank a bottle of claret. Afterwards they went for a walk in a cemetery, where she began to tear up flowers and scratch at the graves. She remembered absolutely nothing of this afterwards. On the 16th she stayed with her friend without anything of importance happening. On the 17th, her friend brought her to Zurich. An acquaintance came with her to the asylum; on the way she talked quite sensibly but was very tired. Outside the asylum they met three boys

whom she described as “three dead people she had dug up.” She then wanted to go to the neighbouring cemetery, and only with difficulty would be persuaded to enter the asylum.

[7] The patient was small, delicately built, slightly anaemic. Left side of the heart slightly enlarged; no murmurs, but a few double beats; accentuated sounds in the mitral region. The liver dulness extended only to the edge of the upper ribs. Patellar reflexes rather brisk, but otherwise no tendon reflexes. No anaesthesia or analgesia, no paralysis. Rough examination of the field of vision with the hands showed no restriction. Hair of a very pale, yellowish-white colour. On the whole, the patient looked her age. She recounted her history and the events of the last few days quite clearly, but had no recollection of what happened in the cemetery at C. or outside the asylum. During the night of the 17th/18th she spoke to the attendant and said she saw the whole room full of dead people looking like skeletons. She was not at all frightened, but was rather surprised that the attendant did not see them too. Once she ran to the window, but was otherwise quiet. The next morning in bed she still saw skeletons, but not in the afternoon. The following night she woke up at four o’clock and heard the dead children in the adjoining cemetery crying out that they had been buried alive. She wanted to go and dig them up but allowed herself to be restrained. Next morning at seven o’clock she was still delirious, but could now remember quite well the events in the cemetery at C. and on her way to the asylum. She said that at C. she wanted to dig up the dead children who were calling to her. She had only torn up the flowers in order to clear the graves and be able to open them. While she was in this state, Professor Bleuler explained to her that she would remember everything afterwards, too, when she came to herself again. The patient slept for a few hours in the morning; afterwards she was quite clear-headed and felt fairly well. She did indeed remember the attacks, but maintained a remarkable indifference towards them. The following nights, except on those of September 22 and 25, she again had short attacks of delirium in which she had to deal with the dead, though the attacks differed in detail. Twice she saw dead people in her bed; she did not appear to be frightened of them, but got out of bed so as not to “embarrass” them. Several times she tried to leave the room.

[8] After a few nights free from attacks, she had a mild one on September 30, when she called to the dead from the window. During the day her mind was quite clear. On October 3, while fully conscious, as she related afterwards, she saw a whole crowd of skeletons in the drawing-room. Although she doubted the reality of the skeletons she could not convince herself that it was an hallucination. The next night, between twelve and one o'clock—the earlier attacks usually happened about this time—she was plagued by the dead for about ten minutes. She sat up in bed, stared into a corner of the room, and said: "Now they're coming, but they're not all here yet. Come along, the room's big enough, there's room for all. When they're all there I'll come too." Then she lay down, with the words: "Now they're all there," and fell asleep. In the morning she had not the slightest recollection of any of these attacks. Very short attacks occurred again on the nights of October 4, 6, 9, 13, and 15, all between twelve and one o'clock. The last three coincided with the menstrual period. The attendant tried to talk to her several times, showed her the lighted street-lamps and the trees, but she did not react to these overtures. Since then the attacks have stopped altogether. The patient complained about a number of troubles she had had during her stay here. She suffered especially from headaches, and these got worse the morning after the attacks. She said it was unbearable. Five grains of Sacch. lactis promptly alleviated this. Then she complained of a pain in both forearms, which she described as though it were tendovaginitis. She thought the bulging of the flexed biceps was a swelling and asked to have it massaged. Actually, there was nothing the matter, and when her complaints were ignored the trouble disappeared. She complained loud and long about the thickening of a toe-nail, even after the thickened part had been removed. Sleep was often disturbed. She would not give her consent to be hypnotized against the night attacks. Finally, on account of headache and disturbed sleep, she agreed to hypnotic treatment. She proved a good subject, and at the first sitting fell into a deep sleep with analgesia and amnesia.

[9] In November she was again asked whether she could remember the attack of September 19, which it had been suggested she would recall. She had great difficulty recollecting it, and in the end she could only recount the main facts; she had forgotten the details.

[10] It remains to be said that the patient was not at all superstitious and in her healthy days had never been particularly interested in the supernatural. All through the treatment, which ended on November 14, she maintained a remarkable indifference both to the illness and its improvement. The following spring she returned as an outpatient for treatment of the headaches, which had slowly come back because of strenuous work during the intervening months. For the rest, her condition left nothing to be desired. It was established that she had no remembrance of the attacks of the previous autumn, not even those of September 19 and earlier. On the other hand, under hypnosis she could still give a good account of the events in the cemetery, outside the asylum, and during the night attacks.

[11] The peculiar hallucinations and general appearance of our case are reminiscent of those states which Krafft-Ebing describes as “protracted states of hysterical delirium.” He says:

> It is in the milder cases of hysteria that such delirious states occur.… Protracted hysterical delirium depends upon temporary exhaustion.… Emotional disturbances seem to favour its outbreak. It is prone to relapse. … Most frequently we find delusions of persecution, with often very violent reactive fear… then religious and erotic delusions. Hallucinations of all the senses are not uncommon. The most frequent and most important are delusions of sight, smell, and touch. The visual hallucinations are mostly visions of animals, funerals, fantastic processions swarming with corpses, devils, ghosts, and what not.… The auditory delusions are simply noises in the ear (shrieks, crashes, bangs), or actual hallucinations, often with sexual content.[4]

[12] The corpse visions of our patient and their appearance during attacks remind us of states occasionally observed in hysteroepilepsy. Here too there are specific visions which, in contrast to protracted delirium, are associated with individual attacks. I will give two examples:

[13] A 30-year-old lady with *grande hystérie* had delirious twilight states in which she was tormented by frightful hallucinations. She saw her children being torn away from her, devoured by wild beasts, *etc*. She had no remembrance of the individual attacks.[5]

[14] A girl of 17, also a severe hysteric. In her attacks she always saw the corpse of her dead mother approaching her, as if to draw her to itself. No memory of the attacks.[6]

[15] These are cases of severe hysteria where consciousness works at a deep dream level. The nature of the attacks and the stability of the hallucinations alone show a certain affinity to our case, which in this respect has numerous analogies with the corresponding states of hysteria, as for instance with cases where a psychic shock (rape, etc.) occasioned the outbreak of hysterical attacks, or where the traumatic event is re-experienced in stereotyped hallucinatory form. Our case, however, gets its specific character from the identity of consciousness during the different attacks. It is a "second state," with a memory of its own, but separated from the waking state by total amnesia. This distinguishes it from the above-mentioned twilight states and relates it to those found in somnambulism.

[16] Charcot[7] divides somnambulism into two basic forms:

a. Delirium with marked inco-ordination of ideas and actions.

b. Delirium with co-ordinated actions. This comes nearer to the waking state.

[17] Our case belongs to the second group. If by somnambulism we understand a state of systematic partial wakefulness,[8] we must when discussing this ailment also consider those isolated attacks of amnesia which are occasionally observed. Except for noctambulism, they are the simplest states of systematic partial wakefulness. The most remarkable in the literature is undoubtedly Naef's case.[8a] It concerns a gentleman of 32 with a bad family history and numerous signs of degeneracy, partly functional, partly organic. As a result of overwork he had, at the early age of 17, a peculiar twilight state with delusions, which lasted a few days and then cleared up with sudden recovery of memory. Later he was subject to frequent attacks of giddiness with palpitations and vomiting, but these attacks were never attended by loss of consciousness. At the end of a feverish illness he suddenly left Australia for Zurich, where he spent some weeks in carefree and merry living, only coming to himself when he read of his sudden disappearance from Australia in the newspapers. He

had complete retrograde amnesia for the period of several months that included his journey to Australia, his stay there, and the journey back. A case of periodic amnesia is published by Azam:[9] Albert X., 12½ years old, with hysterical symptoms, had several attacks of amnesia in the course of a few years, during which he forgot how to read, write, count, and even how to speak his own language, for weeks at a stretch. In between times he was normal.

[18] A case of *automatisme ambulatoire* on a decidedly hysterical basis, but differing from Naef's case in that the attacks were recurrent, is published by Proust:[10] An educated man, aged 30, exhibited all the symptoms of *grande hystérie*. He was very suggestible, and from time to time, under the stress of emotional excitement, had attacks of amnesia lasting from two days to several weeks. While in these states he wandered about, visited relatives, smashed various things in their houses, contracted debts, and was even arrested and convicted for picking pockets.

[19] There is a similar case of vagrancy in Boeteau:[11] A widow of 22, highly hysterical, became terrified at the prospect of an operation for salpingitis, left the hospital where she had been till then, and fell into a somnambulistic condition, from which she awoke after three days with total amnesia. In those three days she had walked about thirty miles looking for her child.

[20] William James[12] describes a case of an "ambulatory sort": the Reverend Ansel Bourne, itinerant preacher, 30 years old, psychopath, had on several occasions attacks of unconsciousness lasting an hour. One day (January 17, 1887) he suddenly disappeared from Greene, Rhode Island, after having lifted $551 from a bank. He was missing for two months, during which time he ran a little grocery store in Norristown, Pennsylvania, under the name of A. J. Brown, carefully attending to all the purchases himself, although he had never done this sort of work before. On March 14 he suddenly awoke and went back home. Complete amnesia for the interval.

[21] Mesnet[13] published this case: F., 27 years old, sergeant in the African regiment, sustained an injury of the parietal bone at Bazeilles. Suffered for a year from hemiplegia, which disappeared when the wound healed.

During the illness he had somnambulistic attacks with marked restriction of consciousness; all the sense functions were paralysed except for the sense of taste and a little bit of the sense of sight. Movements were co-ordinated, but their performance in overcoming obstacles was severely limited. During attacks the patient had a senseless collecting mania. Through various manipulations his consciousness could be given an hallucinatory content; for instance, if a stick was placed in his hand, the patient would immediately feel himself transported to a battle scene, would put himself on guard, see the enemy approaching, etc.

[22] Guinon and Sophie Woltke made the following experiments with hysterics:[14] A blue glass was held in front of a female patient during an hysterical attack, and she regularly saw a picture of her mother in the blue sky. A red glass showed her a bleeding wound, a yellow one an orange-seller or a lady in a yellow dress.

[23] Mesnet's case recalls the cases of sudden restriction of memory.

[24] MacNish[15] tells of a case of this sort: An apparently healthy young woman suddenly fell into an abnormally long sleep, apparently with no prodromal symptoms. On waking she had forgotten the words for and all knowledge of the simplest things. She had to learn how to read, write, and count all over again, at which she made rapid progress. After a second prolonged sleep she awoke as her normal self with no recollection of the intervening state. These states alternated for more than four years, during which time consciousness showed continuity within the two states, but was separated by amnesia from the consciousness of the normal state.

[25] These selected cases of various kinds of changes in consciousness each throw some light on our case. Naef's case presents two hysteriform lapses of memory, one of which is characterized by delusional ideas, and the other by its long duration, restriction of consciousness, and the desire to wander. The peculiar, unexpected impulses are particularly clear in Proust and Mesnet. In our case the corresponding features would be the impulsive tearing up of flowers and the digging up of graves. The patient's continuity of consciousness during attacks reminds us of the way consciousness behaved in the MacNish case; hence it may be regarded as a temporary phenomenon of alternating consciousness. The dreamlike

hallucinatory content of restricted consciousness in our case does not, however, appear to justify us in assigning it without qualification to this “double consciousness” group. The hallucinations in the second state show a certain creativeness which seems to be due to its auto-suggestibility. In Mesnet’s case we observe the appearance of hallucinatory processes through simple stimulations of touch. The patient’s subconscious uses these simple perceptions for the automatic construction of complicated scenes which then take possession of his restricted consciousness. We have to take a somewhat similar view of the hallucinations of our patient; at any rate the outward circumstances in which they arose seem to strengthen this conjecture.

[26] The walk in the cemetery induced the vision of the skeletons, and the meeting with the three boys evoked the hallucination of children buried alive, whose voices the patient heard at night. She came to the cemetery in a somnambulistic condition, which on this occasion was particularly intense in consequence of her having taken alcohol. She then performed impulsive actions of which her subconscious, at least, received certain impressions. (The part played here by alcohol should not be underestimated. We know from experience that it not only acts adversely on these conditions, but, like every other narcotic, increases suggestibility.) The impressions received in somnambulism go on working in the subconscious to form independent growths, and finally reach perception as hallucinations. Consequently our case is closely allied to the somnambulistic dream-states that have recently been subjected to penetrating study in England and France.

[27] The gaps of memory, apparently lacking content at first, acquire such through incidental auto-suggestions, and this content builds itself up automatically to a certain point. Then, probably under the influence of the improvement now beginning, its further development comes to a standstill and finally it disappears altogether as recovery sets in.

[28] Binet and Féré have made numerous experiments with the implanting of suggestions in states of partial sleep. They have shown, for instance, that when a pencil is put into the anaesthetic hand of an hysteric, she will immediately produce long letters in automatic writing whose content is

completely foreign to her consciousness. Cutaneous stimuli in anaesthetic regions are sometimes perceived as visual images, or at least as vivid and unexpected visual ideas. These independent transmutations of simple stimuli must be regarded as the primary phenomenon in the formation of somnambulistic dream pictures. In exceptional cases, analogous phenomena occur even within the sphere of waking consciousness. Goethe,[16] for instance, says that when he sat down, lowered his head, and vividly conjured up the image of a flower, he saw it undergoing changes of its own accord, as if entering into new combinations of form. In the halfwaking state these phenomena occur fairly often as hypnagogic hallucinations. Goethe's automatisms differ from truly somnambulistic ones, because in his case the initial idea is conscious, and the development of the automatism keeps within the bounds laid down by the initial idea, that is to say, within the purely motor or visual area.

[29] If the initial idea sinks below the threshold, or if it was never conscious at all and its automatic development encroaches on areas in the immediate vicinity, then it is impossible to differentiate between waking automatisms and those of the somnambulistic state. This happens, for instance, if the perception of a flower associates itself with the idea of a hand plucking the flower, or with the idea of the smell of a flower. The only criterion of distinction is then simply "more" or "less": in one case we speak of "normal waking hallucinations" and in the other of "somnambulistic dream visions." The interpretation of our patient's attacks as hysterical becomes more certain if we can prove that the hallucinations were probably psychogenic in origin. This is further supported by her complaints (headache and tendovaginitis), which proved amenable to treatment by suggestion. The only aspect that the diagnosis of "hysteria" does not take sufficiently into account is the aetiological factor, for we would after all expect *a priori* that, in the course of an illness which responds so completely to a rest cure, features would now and then be observed which could be interpreted as symptoms of exhaustion. The question then arises whether the early lapses of memory and the later somnambulistic attacks can be regarded as states of exhaustion or as "neurasthenic crises." We know that psychopathic inferiority can give rise to various kinds of epileptoid attacks whose

classification under epilepsy or hysteria is at least doubtful. To quote Westphal:

> On the basis of numerous observations I maintain that the so-called epileptoid attacks form one of the commonest and most frequent symptoms in the group of diseases we reckon among the mental diseases and neuropathies, and that the mere appearance of one or more epileptic or epileptoid attacks is not decisive either for the character and form of the disease or for its course and prognosis.… As already mentioned, I have used the term "epileptoid" in the widest sense for the attack itself.[17]

[30] The epileptoid elements in our case are not far to seek; on the other hand, one can object that the colouring of the whole picture is hysterical in the extreme. As against this we must point out that not every case of somnambulism is *ipso facto* hysterical. Occasionally states occur in typical epilepsy which to experts seem directly parallel with somnambulistic states, or which can be distinguished from hysteria only by the occurrence of genuine convulsions.[18]

[31] As Diehl[19] has shown, neurasthenic inferiority may also give rise to "crises" which often confuse the diagnosis. A definite content of ideas can even repeat itself in stereotyped form in each crisis. Mörchen, too, has recently published the case of an epileptoid neurasthenic twilight state.[20]

[32] I am indebted to Professor Bleuler for the following case: An educated gentleman of middle age, with no epileptic antecedents, had worn himself out with years of mental overwork. Without any other prodromal symptoms (such as depression, etc.), he attempted suicide on a holiday: in a peculiar twilight state he suddenly threw himself into the water from a crowded spot on the river bank. He was immediately hauled out and had only a vague memory of the incident.

[33] With these observations in mind, we must certainly allow neurasthenia a considerable share in the attacks of our patient. The headaches and the "tendovaginitis" point to a mild degree of hysteria, normally latent but becoming manifest under the stress of exhaustion. The genesis of this peculiar illness explains the above-described

relationship to epilepsy, hysteria, and neurasthenia. To sum up: Miss E. suffers from a psychopathic inferiority with a tendency to hysteria. Under the influence of nervous exhaustion she has fits of epileptoid stupor whose interpretation is uncertain at first sight. As a result of an unusually large dose of alcohol, the attacks develop into definite somnambulism with hallucinations, which attach themselves to fortuitous external perceptions in the same way as dreams. When the nervous exhaustion is cured, the hysteriform symptoms disappear.

[34] In the realm of psychopathic inferiority with hysterical colouring, we meet with numerous phenomena which show, as in this case, symptoms belonging to several different clinical pictures, but which cannot with certainty be assigned to any one of them. Some of these states are already recognized as disorders in their own right: e.g., pathological lying, pathological dreaminess, etc. But many of them still await thorough scientific investigation; at present they belong more or less to the domain of scientific gossip. Persons with habitual hallucinations, and also those who are inspired, exhibit these states; they draw the attention of the crowd to themselves, now as poets or artists, now as saviours, prophets, or founders of new sects.

[35] The genesis of the peculiar mentality of these people is for the most part lost in obscurity, for it is only very rarely that one of these singular personalities can be subjected to exact observation. In view of the—sometimes—great historical significance of such persons, it were much to be wished that we had enough scientific material to give us closer insight into the psychological development of their peculiarities. Apart from the now practically useless productions of the pneumatological school at the beginning of the nineteenth century, there is a remarkable dearth of competent observations in the German scientific literature of the subject; indeed, there seems to be a real aversion to investigation in this field. For the facts so far gathered we are indebted almost exclusively to the labours of French and English workers. It therefore seems at least desirable that our literature should be enlarged in this respect. These reflections have prompted me to publish some observations which will perhaps help to broaden our knowledge of the relations between hysterical twilight states and the problems of normal psychology.

[2.] A CASE OF SOMNAMBULISM IN A GIRL WITH POOR INHERITANCE (SPIRITUALISTIC MEDIUM)

[36] The following case was under my observation during the years 1899 and 1900. As I was not in medical attendance upon Miss S. W., unfortunately no physical examination for hysterical stigmata could be made. I kept a detailed diary of the séances, which I wrote down after each sitting. The report that follows is a condensed account from these notes. Out of regard for Miss S. W. and her family, a few unimportant data have been altered and various details omitted from her "romances," which for the most part are composed of very intimate material.

[*Anamnesis*]

[37] Miss S. W., 15½ years old, Protestant. The paternal grandfather was very intelligent, a clergyman who frequently had waking hallucinations (mostly visions, often whole dramatic scenes with dialogues, etc.). A brother of her grandfather was feeble-minded, an eccentric who also saw visions. One of his sisters was also a peculiar, odd character. The paternal grandmother, after a feverish illness in her twentieth year—typhoid fever?—had a trance lasting for three days, from which she did not begin to awake until the crown of her head was burnt with a red-hot iron. Later on, when emotionally excited, she had fainting-fits; these were nearly always followed by a brief somnambulism during which she uttered prophecies. The father too was an odd, original personality with bizarre ideas. Two of his brothers were the same. All three had waking hallucinations. (Second sight, premonitions, etc.) A third brother was also eccentric and odd, talented but one-sided. The mother has a congenital psychopathic inferiority often bordering on psychosis. One sister is an hysteric and a visionary, another sister suffers from "nervous heart-attacks."

[38] S. W. is of delicate build, skull somewhat rachitic though not noticeably hydrocephalic, face rather pale, eyes dark, with a peculiar penetrating look. She has had no serious illnesses. At school she passed for average, showed little interest, was inattentive. In general, her behaviour was rather reserved, but this would suddenly give place to the

most exuberant joy and exaltation. Of mediocre intelligence, with no special gifts, neither musical nor fond of books, she prefers handwork or just sitting around day-dreaming. Even at school she was often absentminded, misread in a peculiar way when reading aloud—for instance, instead of the word “Ziege” (goat) she would say “Geiss,” and instead of “Treppe” (stair) she would say “Stege”; this happened so often that her brothers and sisters used to laugh at her.[21] Otherwise there were no abnormalities to be noticed about S. W., and especially no serious hysterical symptoms. Her family were all artisans and business people with very limited interests. Books of a mystical nature were never allowed in the family. Her education was deficient; apart from the fact that there were many brothers and sisters, all given a very casual education, the children suffered a great deal from the inconsequent, vulgar, and often brutal treatment they received from their mother. The father, a very preoccupied business man, could not devote much time to his children and died when S. W. was still adolescent. In these distressing circumstances it is no wonder that she felt shut in and unhappy. She was often afraid to go home and preferred to be anywhere rather than there. Hence she was left a great deal with her playmates and grew up without much polish. Her educational level was accordingly pretty low and her interests were correspondingly limited. Her knowledge of literature was likewise very limited. She knew the usual poems of Schiller and Goethe and a few other poets learnt by heart at school, some snatches from a song-book, and fragments of the Psalms. Newspaper and magazine stories probably represented the upper limit in prose. Up to the time of her somnambulism she had never read anything of a more cultured nature.

[*Somnambulistic States*]

[39] At home and from friends she heard about table-turning and began to take an interest in it. She asked to be allowed to take part in such experiments, and her desire was soon gratified. In July 1899, she did some table-turning several times in the family circle with friends, but as a joke. It was then discovered that she was an excellent medium. Communications of a serious nature arrived and were received amid

general astonishment. Their pastoral tone was surprising. The spirit gave himself out to be the grandfather of the medium. As I was acquainted with the family, I was able to take part in these experiments. At the beginning of August 1899, I witnessed the first attacks of somnambulism. Their course was usually as follows: S. W. grew very pale, slowly sank to the ground or into a chair, closed her eyes, became cataleptic, drew several deep breaths, and began to speak. At this stage she was generally quite relaxed, the eyelid reflexes remained normal and so did tactile sensibility. She was sensitive to unexpected touches and easily frightened, especially in the initial stage.

[40] She did not react when called by name. In her somnambulistic dialogues she copied in a remarkably clever way her dead relatives and acquaintances, with all their foibles, so that she made a lasting impression even on persons not easily influenced. She could also hit off people whom she knew only from hearsay, doing it so well that none of the spectators could deny her at least considerable talent as an actress. Gradually gestures began to accompany the words, and these finally led up to "attitudes passionnelles" and whole dramatic scenes. She flung herself into postures of prayer and rapture, with staring eyes, and spoke with impassioned and glowing rhetoric. On these occasions she made exclusive use of literary German, which she spoke with perfect ease and assurance, in complete contrast to her usual uncertain and embarrassed manner in the waking state. Her movements were free and of a noble grace, mirroring most beautifully her changing emotions. At this stage her behaviour during the attacks was irregular and extraordinarily varied. Now she would lie for ten minutes to two hours on the sofa or the floor, motionless, with closed eyes; now she assumed a half-sitting posture and spoke with altered voice and diction; now she was in constant movement, going through every possible pantomimic gesture. The content of her speeches was equally variable and irregular. Sometimes she spoke in the first person, but never for long, and then only to prophesy her next attack; sometimes—and this was the most usual—she spoke of herself in the third person. She then acted some other person, either a dead acquaintance or somebody she had invented, whose part she carried out consistently according to the characteristics she herself conceived. The

ecstasy was generally followed by a cataleptic stage with *flexibilitas cerea*, which gradually passed over into the waking state. An almost constant feature was the sudden pallor which gave her face a waxen anaemic hue that was positively frightening. This sometimes occurred right at the beginning of the attack, but often in the second half only. Her pulse was then low but regular and of normal frequency; the breathing gentle, shallow, often barely perceptible. As we have already remarked, S. W. frequently predicted her attacks beforehand; just before the attacks she had strange sensations, became excited, rather anxious, and occasionally expressed thoughts of death, saying that she would probably die in one of these attacks, that her soul only hung on to her body by a very thin thread, so that her body could scarcely go on living. On one occasion after the cataleptic stage, tachypnoea was observed, lasting for two minutes with a respiration of 100 per minute. At first the attacks occurred spontaneously, but later S. W. could induce them by sitting in a dark corner and covering her face with her hands. But often the experiment did not succeed, as she had what she called “good” and “bad” days.

[41] The question of amnesia after the attacks is unfortunately very unclear. This much is certain, that after each attack she was perfectly oriented about the specific experiences she had undergone in the “rapture.” It is, however, uncertain how much she remembered of the conversations for which she served as a medium, and of changes in her surroundings during the attack. It often looked as if she did have a vague recollection, for often she would ask immediately on waking: “Who was there? Wasn’t X or Y there? What did he say?” She also showed that she was superficially aware of the content of the conversations. She often remarked that the spirits told her before waking what they had said. But frequently this was not the case at all. If at her request someone repeated the trance speeches to her, she was very often indignant about them and would be sad and depressed for hours on end, especially if any unpleasant indiscretions had occurred. She would rail against the spirits and assert that next time she would ask her guide to keep such spirits away from her. Her indignation was not faked, for in the waking state she could barely control herself and her affects, so that any change of mood was immediately reflected in her face. At times she seemed barely, if at all,

aware of what went on around her during the attack. She seldom noticed when anyone left the room or came into it. Once she forbade me to enter the room when she was expecting special communications which she wished to keep secret from me. I went in, nevertheless, sat down with the three other sitters, and listened to everything. S. W. had her eyes open and spoke to the others without noticing me. She only noticed me when I began to speak, which gave rise to a veritable storm of indignation. She remembered better, but still only vaguely, the remarks of participants which referred to the trance speeches or directly to herself. I could never discover any definite rapport in this connection.

[42] Besides these "big" attacks, which seemed to follow a certain law, S. W. also exhibited a large number of other automatisms. Premonitions, forebodings, unaccountable moods, and rapidly changing fancies were all in the day's work. I never observed simple states of sleep. On the other hand, I soon noticed that in the middle of a lively conversation she would become all confused and go on talking senselessly in a peculiar monotonous way, looking in front of her dreamily with half-closed eyes. These lapses usually lasted only a few minutes. Then she would suddenly go on: "Yes, what did you say?" At first she would not give any information about these lapses, saying evasively that she felt a bit giddy, had a headache, etc. Later she simply said: "They were there again," meaning her spirits. She succumbed to these lapses very much against her will; often she struggled against them: "I don't want to, not now, let them come another time, they seem to think I'm there only for them." The lapses came over her in the street, in shops, in fact anywhere. If they happened in the street, she would lean against a house and wait till the attack was over. During these attacks, whose intensity varied considerably, she had visions; very often, and especially during attacks when she turned extremely pale, she "wandered," or, as she put it, lost her body and was wafted to distant places where the spirits led her. Distant journeys during ecstasy tired her exceedingly; she was often completely exhausted for hours afterward, and many times complained that the spirits had again drained the strength from her, such exertions were too much, the spirits must get another medium, etc. Once she went hysterically blind for half an hour after the ecstasy. Her gait was unsteady, groping; she had

to be led, did not see the light that stood on the table, though the pupils reacted.

[43] Visions also came in large numbers even without proper lapses (if we use this word only for higher-grade disturbances of attention). At first they were confined to the onset of sleep. A little while after she had gone to bed the room would suddenly light up, and shining white figures detached themselves from the foggy brightness. They were all wrapped in white veil-like robes, the women had things resembling turbans on their heads and wore girdles. Later (according to her own statement) "the spirits were already there" when she went to bed. Finally she saw the figures in broad daylight, though only blurred and fleetingly if there was no real lapse (then the figures became solid enough to touch). But she always preferred the darkness. According to her account, the visions were generally of a pleasant nature. Gazing at the beautiful figures gave her a feeling of delicious bliss. Terrifying visions of a daemonic character were much rarer. These were entirely confined to night-time or dark rooms. Occasionally she saw black figures in the street at night or in her room; once in the dark hallway she saw a terrible copper-red face which suddenly glared at her from very near and terrified her. I could not find out anything satisfactory about the first occurrence of the visions. She stated that in her fifth or sixth year she once saw her "guide" at night—her grandfather (whom she had never known in life). I could not obtain any objective clues about this early vision from her relatives. Nothing more of the kind is said to have happened until the first séance. Except for the hypnagogic brightness and "seeing sparks" there were never any rudimentary hallucinations; from the beginning the hallucinations were of a systematic nature involving all the sense organs equally. So far as the intellectual reaction to these phenomena is concerned, what is remarkable is the amazing matter-of-factness with which she regarded them. Her whole development into a somnambulist, her innumerable weird experiences, seemed to her entirely natural. She saw her whole past only in this light. Every in any way striking event from her earlier years stood in a clear and necessary relationship to her present situation. She was happy in the consciousness of having found her true vocation. Naturally she was unshakably convinced of the reality of her visions. I often tried to

give her some critical explanation, but she would have none of it, since in her normal state she could not grasp a rational explanation anyway, and in her semi-somnambulistic state she regarded it as senseless in view of the facts staring her in the face. She once said: “I do not know if what the spirits say and teach me is true, nor do I know if they really are the people they call themselves; but that my spirits exist is beyond question. I see them before me, I can touch them. I speak to them about everything I wish as naturally as I’m talking to you. They must be real.” She absolutely would not listen to the idea that the manifestations were a kind of illness. Doubts about her health or about the reality of her dream-world distressed her deeply; she felt so hurt by my remarks that she closed up in my presence and for a long time refused to experiment if I was there; hence I took care not to express my doubts and misgivings aloud. On the other hand she enjoyed the undivided respect and admiration of her immediate relatives and acquaintances, who asked her advice about all sorts of things. In time she obtained such an influence over her followers that three of her sisters began to hallucinate too. The hallucinations usually began as night-dreams of a very vivid and dramatic kind which gradually passed over into the waking state—partly hypnagogic, partly hypnopompic. A married sister in particular had extraordinarily vivid dreams that developed logically from night to night and finally appeared in her waking consciousness first as indistinct delusions and then as real hallucinations, but they never reached the plastic clearness of S. W.’s visions. Thus, she once saw in a dream a black daemonic figure at her bedside in vigorous argument with a beautiful white figure who was trying to restrain the black; nevertheless the black figure seized her by the throat and started to choke her; then she awoke. Bending over her she saw a black shadow with human outlines, and near it a cloudy white figure. The vision disappeared only when she lighted the candle. Similar visions were repeated dozens of times. The visions of the other two sisters were similar but less intense.

[44] The type of attack we have described, with its wealth of fantastic visions and ideas, had developed in less than a month, reaching a climax which was never to be surpassed. What came later was only an elaboration of all the thoughts and the cycles of visions that had been

more or less foreshadowed right at the beginning. In addition to the “big attacks” and the “little lapses,” whose content however was materially the same, there was a third category that deserves mention. These were the semi-somnambulistic states. They occurred at the beginning or end of the big attacks, but also independently of them. They developed slowly in the course of the first month. It is not possible to give a more precise date for their appearance. What was especially noticeable in this state was the rigid expression of the face, the shining eyes, and a certain dignity and stateliness of movement. In this condition S. W. was herself, or rather her somnambulist ego. She was fully oriented to the external world but seemed to have one foot in her dream-world. She saw and heard her spirits, saw how they walked round the room among those present, standing now by one person and now by another. She had a clear memory of her visions, of her journeys, and the instructions she received. She spoke quietly, clearly, and firmly, and was always in a serious, almost solemn, mood. Her whole being glowed with deep religious feeling, free from any pietistic flavour, and her speech was in no way influenced by the Biblical jargon of her guide. Her solemn behaviour had something sorrowful and melancholy about it. She was painfully conscious of the great difference between her nocturnal ideal world and the crude reality of day. This state was in sharp contrast to her waking existence; in it there was no trace of that unstable and inharmonious creature, of that brittle nervous temperament which was so characteristic of her usual behaviour. Speaking with her, you had the impression of speaking with a much older person, who through numerous experiences had arrived at a state of calm composure. It was in this state that she achieved her best results, whereas her romances corresponded more closely to her waking interests. The semi-somnambulism usually appeared spontaneously, as a rule during the table-turning experiments, and it always began by S. W.’s knowing beforehand what the table was going to say. She would then stop table-turning and after a short pause would pass suddenly into an ecstasy. She proved to be very sensitive. She could guess and answer simple questions devised by a member of the circle who was not himself a medium. It was enough to lay a hand on the table, or on her hands, to give her the necessary clues. Direct thought transference could never be established. Beside the obvious broadening of her whole personality the continued existence of her ordinary character was all the more startling. She talked with unconcealed pleasure about all her little childish experiences, the flirtations and love secrets, the naughtiness and rudeness of her companions and playmates. To anyone who did not know her secret she was just a girl of 15½, no different from thousands of other girls. So much the greater was people's astonishment when they came to know her other side. Her relatives could not grasp the change at first; part of it they never understood at all, so that there were often bitter arguments in the family, some of them siding with S. W. and others against her, either with gushing enthusiasm or with contemptuous censure of her "superstition." Thus S. W., during the time that I knew her, led a curiously contradictory life, a real "double life" with two personalities existing side by side or in succession, each continually striving for mastery. I will now give some of the most interesting details of the séances in chronological order.

[*Records of Séances*]

[45] FIRST AND SECOND SITTINGS (August 1899). S. W. at once took control of the "communications." The "psychograph," for which an overturned tumbler was used, the two fingers of the right hand being placed upon it, moved with lightning speed from letter to letter. (Slips of paper, marked with letters and numbers, had been arranged in a circle round the glass.) It was communicated that the medium's grandfather was present and would speak to us. There now followed numerous communications in quick succession, mostly of an edifying religious character, partly in properly formed words and partly with the letters transposed or in reverse order. These latter words and sentences were often produced so rapidly that one could not follow the meaning and only discovered it afterwards by reversing the letters. Once the messages were interrupted in brusque fashion by a new communication announcing the presence of the writer's grandfather. Someone remarked jokingly: "Evidently the two spirits don't get on very well together." Darkness came on during the experiment. Suddenly S. W. became very agitated, jumped up nervously, fell on her knees, and cried: "There, there, don't you see that light, that star there?" She grew more and more excited, and called for a lamp in terror. She was pale, wept, said she felt queer, did not know what was the matter with her.

When a lamp was brought she quieted down. The experiments were suspended.

[46] At the next sitting, which took place two days later, also in the evening, similar communications were obtained from S. W.'s grandfather. When darkness fell she suddenly lay back on the sofa, grew pale, closed her eyes to a slit, and lay there motionless. The eyeballs were turned upwards, the eye-lid reflex was present, also tactile sensibility. Respiration gentle, almost imperceptible. Pulse low and feeble. This condition lasted about half an hour, whereupon she suddenly got up with a sigh. The extreme pallor of the face, which had lasted all through the attack, now gave way to her usual rosy colour. She was somewhat confused and embarrassed, said she had seen "all sorts" of things, but would tell nothing. Only after insistent questioning would she admit that in a peculiar waking condition she had seen her grandfather arm-in-arm with my grandfather. Then they suddenly drove past sitting side by side in an open carriage.

[47] THIRD SITTING. In this, which took place a few days later, there was a similar attack of more than half an hour's duration. S. W. afterwards told of many white transfigured forms who each gave her a flower of special symbolic significance. Most of them were dead relatives. Concerning the details of their talk she maintained an obstinate silence.

[48] FOURTH SITTING. After S. W. had passed into the somnambulistic state she began to make peculiar movements with her lips, emitting at the same time gulping and gurgling noises. Then she whispered something unintelligible very softly. When this had gone on for some minutes she suddenly began speaking in an altered, deep tone of voice. She spoke of herself in the third person: "She is not here. she has gone away." There now followed several sentences in a religious vein. From their content and language one could see that she was imitating her grandfather, who had been a clergyman. The gist of the talk did not rise above the mental level of the "communications." The tone of voice had something artificial and forced about it, and only became natural when in due course it grew more like the medium's own. (In later sittings the voice only altered for a few moments when a new spirit manifested itself.) Afterwards she had no

remembrance of the trance conversation. She gave hints about a sojourn in the other world and spoke of the unimaginable blessedness she felt. It should be noted that during the attack her talk was absolutely spontaneous and not prompted by any suggestions.

[49] Immediately after this sitting S. W. became acquainted with Justinus Kerner's book *Die Seherin von Prevorst.*[22] She thereupon began to magnetize herself towards the end of the attacks, partly by means of regular passes, partly by strange circles and figures of eight which she executed symmetrically with both arms at once. She did this, she said, to dispel the severe headaches that came after the attacks. In other August sittings (not detailed here) the grandfather was joined by numerous kindred spirits who did not produce anything very remarkable. Each time a new spirit appeared, the movements of the glass altered in a startling way: it ran along the row of letters, knocking against some of them, but no sense could be made of it. The spelling was very uncertain and arbitrary, and the first sentences were often incomplete or broken up into meaningless jumbles of letters. In most cases fluent writing suddenly began at this point. Sometimes automatic writing was attempted in complete darkness. The movements began with violent jerkings of the whole arm, so that the pencil went right through the paper. The first attempt consisted of numerous strokes and zigzag lines about 8 cm. high. Further attempts first produced illegible words written very large, then the writing gradually grew smaller and more distinct. It was not much different from the medium's own. The control spirit was once again the grandfather.

[50] FIFTH SITTING. Somnambulistic attacks in September 1899. S. W. sat on the sofa, leant back, shut her eyes, breathing lightly and regularly. She gradually became cataleptic. The catalepsy disappeared after about two minutes, whereupon she lay there apparently sleeping quietly, muscles quite relaxed. Suddenly she began talking in a low voice: "No, you take the red, I'll take the white. You can take the green, and you the blue. Are you ready? Let's go." (Pause of several minutes, during which her face assumed a corpse-like pallor. Her hands felt cold and were quite bloodless.) Suddenly she called out in a loud solemn voice: "Albert, Albert, Albert," then in a whisper: "Now you speak," followed by a

longer pause during which the pallor of her face reached its highest conceivable intensity. Again in a loud solemn voice: “Albert, Albert, don’t you believe your father? I tell you there are many mistakes in N’s teaching. Think about it.” Pause. The pallor decreased. “He’s very frightened, he couldn’t speak any more.” (These words in her usual conversational tone.) Pause. “He will certainly think about it.” She went on speaking in the same conversational tone but in a strange idiom that sounded like French and Italian mixed, recalling now one and now the other. She spoke fluently, rapidly, and with charm. It was possible to make out a few words, but not to memorize them, because the language was so strange. From time to time certain words recurred, like *wena*, *wenes*, *wenai*, *wene*, etc. The absolute naturalness of the performance was amazing. Now and then she paused as if someone were answering her. Suddenly she said, in German: “Oh dear, is it time already?” (In a sad voice.) “Must I go? Goodbye, goodbye!” At these words there passed over her face an indescribable expression of ecstatic happiness. She raised her arms, opened her eyes, till now closed, and looked upwards radiantly. For a moment she remained in this position, then her arms sank down slackly, her face became tired and exhausted. After a short cataleptic stage she woke up with a sigh. “I’ve slept again, haven’t I?” She was told she had been talking in her sleep, whereupon she became wildly annoyed, and her anger increased still more when she learned that she was talking in a foreign language. “But I told the spirits I didn’t want to, I can’t do it, it tires me too much.” (Began to cry.) “Oh God, must everything, everything come back again like last time, am I to be spared nothing?”

[51] The next day at the same time there was another attack. After S. W. had dropped off, Ulrich von Gerbenstein suddenly announced himself. He proved to be an amusing gossip, speaking fluent High German with a North German accent. Asked what S. W. was doing, he explained with much circumlocution that she was far away, and that he was here meanwhile to look after her body, its circulation, respiration, etc. He must take care that no black person got hold of her and harmed her. On insistent questioning he said that S. W. had gone with the others to Japan, to look up a distant relative and stop him from a stupid marriage. He then announced in a whisper the exact moment when the meeting took place.

Forbidden to talk for a few minutes, he pointed to S. W.'s sudden pallor, remarking that materialization at such great distances cost a corresponding amount of strength. He then ordered cold compresses to be applied to her head so as to alleviate the severe headache which would come afterwards. With the gradual return of colour to her face, the conversation became more animated. There were all sorts of childish jokes and trivialities, then U. v. G. suddenly said: "I see them coming, but they are still very far off; I see her there like a little star." S. W. pointed to the north. We naturally asked in astonishment why they were not coming from the east, whereupon U. v. G. laughingly replied: "They come the direct way over the North Pole. I must go now, goodbye." Immediately afterwards S. W. awoke with a sigh, in a bad temper, complaining of violent headache. She said she had seen U. v. G. standing by her body; what had he told us? She was furious about the "silly chatter," why couldn't he lay off it for once?

[52] SIXTH SITTING. Began in the usual way. Extreme pallor; lay stretched out, scarcely breathing. Suddenly she spoke in a loud solemn voice: "Well then, be frightened; I am. I warn you about N's teaching. Look, in hope there is everything needed for faith. You want to know who I am? God gives where one least expects it. Don't you know me?" Then unintelligible whispering. After a few minutes she woke up.

[53] SEVENTH SITTING. S. W. soon fell asleep, stretched out on the sofa. Very pale. Said nothing, sighed deeply from time to time. Opened her eyes, stood up, sat down on the sofa, bent forward, saying softly: "You have sinned grievously, have fallen far." Bent still further forward as if speaking to someone kneeling in front of her. Stood up, turned to the right, stretched out her hand, and pointed to the spot over which she had been bending: "Will you forgive her?" she asked loudly. "Do not forgive men, but their spirits. Not she, but her human body has sinned." Then she knelt down, remained for about ten minutes in an attitude of prayer. Suddenly she got up, looked to heaven with an ecstatic expression, and then threw herself on her knees again, her face in her hands, whispering incomprehensible words. Remained motionless in this attitude for several minutes. Then she got up, gazed heavenward again with radiant countenance, and lay down on the sofa, waking soon afterwards.

Development of the Somnambulistic Personalities

[54] At the beginning of many séances, the glass was allowed to move by itself, and this was always followed by the stereotyped invitation: “You must ask a question.” Since several convinced spiritualists were attending the séances, there was of course an immediate demand for all manner of spiritualistic marvels, especially for the “protecting spirits.” At these requests the names of well-known dead persons were sometimes produced, and sometimes unknown names such as Berthe de Valours, Elisabeth von Thierfelsenburg, Ulrich von Gerbenstein, etc. The control spirit was almost without exception the medium’s grandfather, who once declared that “he loved her more than anyone in this world because he had protected her from childhood up and knew all her thoughts.” This personality produced a flood of Biblical maxims, edifying observations, and song-book verses, also verses he had presumably composed himself, like the following:

> Be firm and true in thy believing,
> To faith in God cling ever nigh,
> Thy heavenly comfort never leaving,
> Which having, man can never die.
> Refuge in God is peace for ever
> When earthly cares oppress the mind;
> Who from the heart can pray is never
> Bow’d down by fate howe’er unkind.

[55] Numerous other effusions of this sort betrayed by their hackneyed, unctuous content their origin in some tract or other. From the time S. W. began speaking in her ecstasies, lively dialogues developed between members of the circle and the somnambulist personality. The gist of the answers received was essentially the same as the banal and generally edifying verbiage of the psychographic communications. The character of this personality was distinguished by a dry and tedious solemnity, rigorous conventionality, and sanctimonious piety (which does not accord, at all with the historical reality). The grandfather was the medium’s guide and protector. During the ecstasies he offered all kinds of advice, prophesied later attacks and what would happen when she woke, etc. He ordered cold compresses, gave instructions concerning the way the medium should lie on the couch, arrangements for sittings, and so on.

His relationship to the medium was exceedingly tender. In vivid contrast to this heavy-footed dream-personage, there appeared a personality who had cropped up occasionally in the psychographic communications of the first sittings. He soon disclosed himself as the dead brother of a Mr. R., who was then taking part in the séances. This dead brother, Mr. P. R., peppered his living brother with commonplaces about brotherly love, etc. He evaded specific questions in every possible way. At the same time he developed a quite astonishing eloquence toward the ladies of the circle, and in particular paid his attentions to a lady whom he had never known in life. He stated that even when alive he had always raved about her, had often met her in the street without knowing who she was, and was now absolutely delighted to make her acquaintance in this unusual manner. His stale compliments, pert remarks to the men, innocuous childish jokes, etc., took up a large part of the séances. Several members of the circle took exception to the frivolity and banality of this spirit, whereupon he vanished for one or two sittings, but soon reappeared, at first well-behaved, often with Christian phrases on his lips, but before long slipping back into his old form.

[56] Besides these two sharply differentiated personalities, others appeared who varied but little from the grandfather type; they were mostly dead relatives of the medium. The general atmosphere of the first two months' séances was accordingly solemn and edifying, disturbed only from time to time by P. R.'s trivial chatter. A few weeks after the beginning of the séances Mr. R. left our circle, whereupon a remarkable change took place in P. R.'s behaviour. He grew monosyllabic, came less often, and after a few sittings vanished altogether. Later on he reappeared very occasionally, and mostly only when the medium was alone with the lady in question. Then a new personality thrust himself to the forefront; unlike P. R., who always spoke Swiss dialect, this gentleman affected a strong North German accent. In all else he was an exact copy of P. R. His eloquence was astonishing, since S. W. had only a very scanty knowledge of High German, whereas this new personality, who called himself Ulrich von Gerbenstein, spoke an almost faultless German abounding in amiable phrases and charming compliments.[23]

[57] Ulrich von Gerbenstein was a gossip, a wag, and an idler, a great admirer of the ladies, frivolous and extremely superficial. During the winter of 1899/1900 he came to dominate the situation more and more, and took over one by one all the above-mentioned functions of the grandfather, so that the serious character of the séances visibly deteriorated under his influence. All efforts to counteract it proved unavailing, and finally the séances had to be suspended on this account for longer and longer periods.

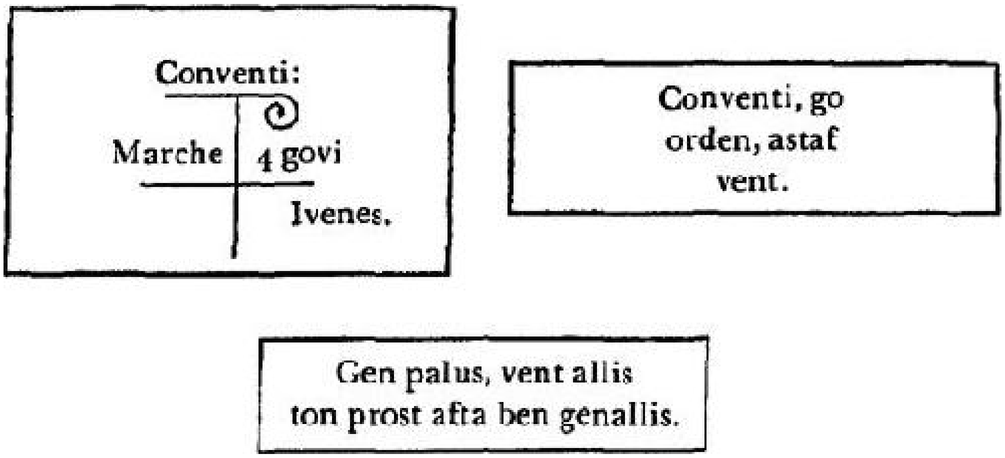
[58] One feature which all these somnambulist personalities have in common deserves mention. They have at their disposal the whole of the medium's memory, even the unconscious portion of it, they are also *au courant* with the visions she has in the ecstatic state, but they have only the most superficial knowledge of her fantasies during the ecstasy. Of the somnambulistic dreams they only know what can occasionally be picked up from members of the circle. On doubtful points they can give no information, or only such as contradicts the medium's own explanations. The stereotyped answer to all questions of this kind is "Ask Ivenes, Ivenes knows."[24] From the examples we have given of the different ecstasies it is clear that the medium's consciousness is by no means idle during the trance, but develops an extraordinarily rich fantasy activity. In reconstructing her somnambulistic ego we are entirely dependent on her subsequent statements, for in the first place the spontaneous utterances of the ego associated with the waking state are few and mostly disjointed, and in the second place many of the ecstasies pass off without pantomime and without speech, so that no conclusions about inner processes can be drawn from external appearances. S. W. is almost totally amnesic in regard to the automatic phenomena during ecstasy, in so far as these fall within the sphere of personalities foreign to her ego. But she usually has a clear memory of all the other phenomena directly connected with her ego, such as talking in a loud voice, glossolalia, etc. In every instance, there is complete amnesia only in the first few moments after the ecstasy. During the first half hour, when a kind of semi-somnambulism with reveries, hallucinations, etc. is still present, the amnesia gradually disappears, and fragmentary memories come up of what has happened, though in a quite irregular and arbitrary fashion.

[59] The later séances usually began by our joining hands on the table, whereupon the table immediately started to move. Meanwhile S. W. gradually became somnambulistic, took her hands from the table, lay back on the sofa, and fell into an ecstatic sleep. She sometimes related her experiences to us afterwards, but was very reticent if strangers were present. Even after the first few ecstasies, she hinted that she played a distinguished role among the spirits. Like all the spirits, she had a special name, and hers was Ivenes; her grandfather surrounded her with quite particular care, and in the ecstasy with the flower-vision she learnt special secrets about which she still maintained the deepest silence. During the séances when her spirits spoke she made long journeys, mostly to relatives whom she visited, or she found herself in the Beyond, in "that space between the stars which people think is empty, but which really contains countless spirit worlds." In the semi-somnambulistic state that frequently followed her attacks she once gave a truly poetic description of a landscape in the Beyond, "a wonderful moonlit valley that was destined for generations as yet unborn." She described her somnambulistic ego as a personality almost entirely freed from the body: a small but fully grown black-haired woman, of a markedly Jewish type, clothed in white garments, her head wrapped in a turban. As for herself, she understood and spoke the language of the spirits—for the spirits still speak with one another from human habit, although they don't really need to because they can see one another's thoughts. She did not always actually talk with them, she just looked at them and knew what they were thinking. She travelled in the company of four or five spirits, dead relatives, and visited her living relatives and acquaintances in order to investigate their life and way of thinking; she also visited all the places that lay on her ghostly beat. After becoming acquainted with Kerner's book, she (like the Clairvoyante) felt it her destiny to instruct and improve the black spirits who are banished to certain regions or who dwell partly beneath the earth's surface. This activity caused her a good deal of trouble and pain; both during and after the ecstasies she complained of suffocating feelings, violent headaches, etc. But every fortnight, on Wednesdays, she was allowed to spend the whole night in the gardens of the Beyond in the company of the blessed spirits. There she received instruction concerning the forces that govern the world and the endlessly complicated

relationships between human beings, and also concerning the laws of reincarnation, the star-dwellers, etc. Unfortunately she expatiated only on the system of world-forces and reincarnation, and merely let fall an occasional remark concerning the other subjects. For instance, she once returned from a railway journey in an extremely agitated state. We thought at first that something unpleasant must have happened to her; but finally she pulled herself together and explained that “a star-dweller had sat opposite her in the train.” From the description she gave of this being I recognized an elderly merchant I happened to know, who had a rather unsympathetic face. Apropos of this event, she told us all the peculiarities of the star-dwellers: they have no godlike souls, as men have, they pursue no science, no philosophy, but in the technical arts they are far more advanced than we are. Thus, flying machines have long been in existence on Mars; the whole of Mars is covered with canals, the canals are artificial lakes and are used for irrigation. The canals are all flat ditches, the water in them is very shallow. The excavating of the canals caused the Martians no particular trouble, as the soil there is lighter than on earth. There are no bridges over the canals, but that does not prevent communication because everybody travels by flying machine. There are no wars on the stars, because no differences of opinion exist. The star-dwellers do not have a human shape but the most laughable ones imaginable, such as no one could possibly conceive. Human spirits who get permission to travel in the Beyond are not allowed to set foot on the stars. Similarly, travelling star-dwellers may not touch down on earth but must remain at a distance of some 75 feet above its surface. Should they infringe this law, they remain in the power of the earth and must take on human bodies, from which they are freed only after their natural death. As human beings they are cold, hard-hearted, and cruel. S. W. can recognize them by their peculiar expression, which lacks the “spiritual,” and by their hairless, eyebrowless, sharply cut faces. Napoleon I was a typical star-dweller.

[60] On her journeys she did not see the places through which she hastened. She had the feeling of floating, and the spirits told her when she was in the right spot. Then, as a rule, she saw only the face and upper part of the person before whom she wished to appear or whom she wanted to

see. She could seldom say in what kind of surroundings she saw this person. Occasionally she saw me, but only my head without any background. She was much occupied with the enchanting of spirits, and for this purpose wrote oracular sayings in a foreign tongue on slips of paper which she concealed in all sorts of queer places. Especially displeasing to her was the presence in my house of an Italian murderer, whom she called Conventi. She tried several times to cast a spell on him, and without my knowledge concealed several slips of paper about the place, which were later found by accident. One of them had the following message written on it (in red pencil):



Conventi:
Marche
4 govi
Ivenes.

Conventi, go
orden, astaf
vent.

Gen palus, vent allis
ton prost afta ben genallis.

Figure 1

[61] Unfortunately I never managed to get a translation, for in this matter S. W. was quite unapproachable.

[62] Occasionally the somnambulistic Ivenes spoke directly to the public. She did so in dignified language that sounded slightly precocious, but Ivenes was not boringly unctuous or irrepressibly silly like her two guides; she is a serious, mature person, devout and right-minded, full of womanly tenderness and very modest, who always submits to the opinion of others. There is something soulful and elegiac about her, an air of melancholy resignation; she longs to get out of this world, she returns unwillingly to reality, she bemoans her hard lot, her odious family circumstances. With all this she is something of a great lady; she orders her spirits about, despises von Gerbenstein’s stupid “chatter,” comforts others, succours those in distress, warns and protects them from dangers to body and soul. She is the channel for the entire intellectual output of all

the manifestations, though she herself ascribes this to instruction by the spirits. It is Ivenes who directly controls S. W.'s semi-somnambulistic state.

The Romances

[63] The peculiar ghostlike look in S. W.'s eyes during her semi-somnambulism prompted some members of the circle to compare her to the Clairvoyante of Prevorst. The suggestion was not without consequences. S. W. gave hints of earlier existences she had already lived through, and after a few weeks she suddenly disclosed a whole system of reincarnations, although she had never mentioned anything of the sort before. Ivenes, she said, was a spiritual being who had certain advantages over the spirits of other human beings. Every human spirit must embody itself in the course of the centuries. But Ivenes had to embody herself at least once every two hundred years; apart from her, only two human beings shared this fate, namely Swedenborg and Miss Florence Cook (Crookes's[24a] famous medium). S. W. called these two personages her brother and sister. She gave no information about their previous existences. At the beginning of the nineteenth century, Ivenes had been Frau Hauffe, the Clairvoyante of Prevorst, and at the end of the eighteenth century a clergyman's wife in central Germany (locality unspecified), in which capacity she had been seduced by Goethe and had borne him a son. In the fifteenth century she had been a Saxon countess, with the poetic name of Thierfelsenburg. Ulrich von Gerbenstein was a relative from that time. The lapse of three hundred years before her next incarnation, and the slip-up with Goethe, had to be atoned for by the sorrows of the Clairvoyante. In the thirteenth century, she had been a noblewoman with the name of de Valours, in the south of France, and had been burnt as a witch. From the thirteenth century back to the time of the Christian persecutions under Nero there had been numerous reincarnations, of which S. W. gave no account. During the Christian persecutions she had played a martyr's part. Then came another great darkness, back to the time of David, when Ivenes had been an ordinary Jewess. After her death as such, she had received from Astaf, an angel in one of the higher heavens, the mandate for her wonderful career. In all her

pre-existences she had been a medium and an intermediary between this world and the Beyond. Her brothers and sisters were equally old and had the same profession. In each of her pre-existences she had invariably been married, and in this way founded a colossal family tree, with whose endlessly complicated relationships she was occupied in many of her ecstasies. Thus, some time in the eighth century she had been the mother of her earthly father and, what is more, of her grandfather and mine. Hence the remarkable friendship between these two old gentlemen, otherwise strangers. As Mme. de Valours she had been my mother. When she had been burnt as a witch I had taken it very much to heart; I had retired to a monastery in Rouen, wore a grey habit, became prior, wrote a work on botany, and died at over eighty years of age. In the refectory of the monastery there had hung a portrait of Mme. de Valours, in which she was depicted in a half-sitting, half-reclining position. (S. W. in the semi-somnambulistic state often assumed this position on the sofa. It corresponds exactly to that of Mme. Récamier in David’s well-known painting.) A gentleman who often took part in the séances and bore a distant resemblance to me was also one of her sons from that time. Around this core of relationships there now grouped themselves, at a greater or lesser distance, all the persons in any way related or known to her. One came from the fifteenth century, another was a cousin from the eighteenth century, and so on.

[64] From the three great family stocks there sprang the greater part of the races of Europe. She and her brothers and sisters were descended from Adam, who arose by materialization; the other races then in existence, from among whom Cain took his wife, were descended from monkeys. From these interrelated groups S. W. produced a vast amount of family gossip, a spate of romantic stories, piquant adventures, etc. The special target of her romances was a lady acquaintance of mine, who for some undiscoverable reason was peculiarly antipathetic to her. She declared that this lady was the incarnation of a celebrated Parisian poisoner who had achieved great notoriety in the eighteenth century. This lady, she maintained, still continued her dangerous work, but in a much more ingenious and refined fashion than before. Through the inspiration of the wicked spirits who accompanied her, she had discovered a fluid which

when merely exposed to the air attracted any tubercle bacilli flying about and formed a splendid culture medium for them. By means of this fluid, which she was in the habit of mixing with food, she had caused the death of her husband (who had indeed died from tuberculosis), also of one of her lovers and of her own brother, so as to get his inheritance. Her eldest son was an illegitimate child by her lover. During her widowhood she had secretly borne an illegitimate child to another lover, and had finally had illicit relations with her own brother, whom she later poisoned. In this way S. W. wove innumerable stories in which she believed implicitly. The characters in these romances also appeared in her visions, as for instance this lady in the above-mentioned vision with its pantomime of confession and forgiveness of sin. Anything at all interesting that happened in her surroundings was drawn into this system of romances and given a place in the family relationships with a more or less clear account of the pre-existences and influencing spirits. So it fared with all persons who made S. W.'s acquaintance: they were rated as a second or a first incarnation according to whether they had a well-marked or an indistinct character. In most cases they were also designated as relatives and always in the same quite definite way. Only afterwards, often several weeks later, a new and complicated romance would suddenly make its appearance after an ecstasy, explaining the striking relationship by means of pre-existences or illegitimate liaisons. Persons sympathetic to S. W. were usually very close relatives. These family romances (with the exception of the one described above) were all composed very carefully, so that it was absolutely impossible to check up on them. They were delivered with the most amazing aplomb and often surprised us by the extremely clever use of details which S. W. must have heard or picked up from somewhere. Most of the romances had a pretty gruesome character: murder by poison and dagger, seduction and banishment, forgery of wills, and so forth played a prominent role.

Mystic Science

[65] S. W. was subjected to numerous suggestions in regard to scientific questions. Generally, towards the end of the séances, various subjects of a scientific or spiritualistic nature were discussed and debated. S. W. never

took part in the conversation, but sat dreamily in a corner in a semi-somnambulistic condition. She listened now to one thing and now to another, catching it in a half dream, but she could never give a coherent account of anything if one asked her about it, and she only half understood the explanations. In the course of the winter, various hints began to emerge in the séances: "The spirits brought her strange revelations about the world forces and the Beyond, but she could not say anything just now." Once she tried to give a description, but only said "on one side was the light, on the other side the power of attraction." Finally, in March 1900, after nothing more had been heard of these things for some time, she suddenly announced with a joyful face that she had now received everything from the spirits. She drew forth a long narrow strip of paper on which numerous names were written. Despite my request she would not let it out of her hands, but told me to draw a diagram [fig. 2].

[66] I can remember clearly that in the winter of 1899/1900 we spoke several times in S. W.'s presence of attractive and repulsive forces in connection with Kant's *Natural History and Theory of the Heavens,*[25] also of the law of the conservation of energy, of the different forms of energy, and of whether the force of gravity is also a form of motion. From the content of these talks S. W. had evidently derived the foundations of her mystic system. She gave the following explanations: The forces are arranged in seven circles. Outside these there are three more, containing unknown forces midway between force and matter. Matter is found in seven outer circles surrounding the ten inner ones.[26] In the centre stands the Primary Force; this is the original cause of creation and is a spiritual force. The first circle which surrounds the Primary Force is Matter, which is not a true force and does not arise from the Primary Force. But it combines with the Primary Force and from this combination arise other spiritual forces: on one side the Good or Light Powers [Magnesor], on the other side the Dark Powers [Connesor]. The Magnesor Power contains the most Primary Force, and the Connesor Power the least, since there the dark power of matter is greatest. The further the Primary Force advances outwards the weaker it becomes, but weaker too becomes the power of matter, since its power is greatest where the collision with the Primary Force is most violent, i.e., in the Connesor Power. In every circle there

are analogous forces of equal strength working in opposite directions. The system could also be written out in a single line or column, beginning with Primary Force, Magnesor, Cafar, etc., and then—going from left to right on the diagram—up through Tusa and Endos to Connesor; but in that way it would be difficult to see the different degrees of intensity. Every force in an outer circle is composed of the nearest adjacent forces of the inner circle.

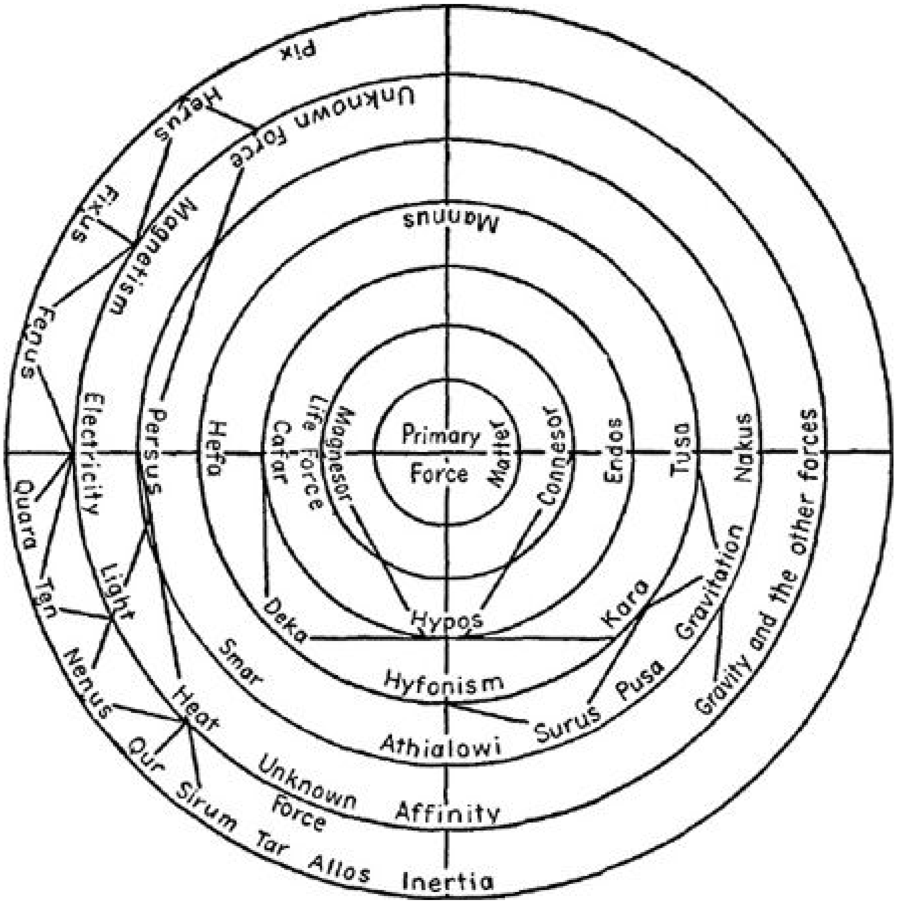


Figure 2

[67] The Magnesor Group. From Magnesor descend in direct line the so-called Powers of Light, which are only slightly influenced by the dark side. Magnesor and Cafar together form the Life Force, which is not uniform but is differently composed in animals and plants. Man’s life-force stands between Magnesor and Cafar. Morally good persons and mediums who facilitate communication between good spirits and the earth have most Magnesor. Somewhere about the middle are the life-forces of animals, and in Cafar those of plants. Nothing is known about

Hefa, or rather S. W. can give no information. Persus is the basic force that manifests itself in the forces of motion. Its recognizable forms are Heat, Light, Electricity, Magnetism, and two unknown forces, one of which is to be found only in comets. Of the forces in the sixth circle, S. W. could only name North and South Magnetism and Positive and Negative Electricity. Deka is unknown. Smar is of special significance, to be discussed below; it leads over to:

[68] THE HYPOS GROUP. Hypos and Hyfonism are powers which dwell only in certain human beings, in those who are able to exert a magnetic influence on others. Athialowi is the sexual instinct. Chemical affinity is directly derived from it. In the seventh circle comes Inertia. Surus and Kara are of unknown significance. Pusa corresponds to Smar in the opposite sense.

[69] THE CONNESOR GROUP. Connesor is the counterpole to Magnesor. It is the dark and evil power equal in intensity to the good power of Light. What the good power creates it turns into its opposite. Endos is a basic power in minerals. From Tusa (significance unknown) is derived Gravitation, which in its turn is described as the basic power manifesting itself in the forces of resistance (gravity, capillarity, adhesion, and cohesion). Nakus is the secret power in a rare stone which counteracts the effect of snake poison. The two powers Smar and Pusa have a special significance. According to S. W., Smar develops in the bodies of morally good people at the moment of death. This power enables the soul to ascend to the powers of Light. Pusa works the opposite way, for it is the power that leads the morally bad soul into the state of Connesor on the dark side.

[70] With the sixth circle the visible world begins; this appears to be so sharply divided from the Beyond only because of the imperfection of our organs of sense. In reality the transition is a very gradual one, and there are people who live on a higher plane of cosmic knowledge because their perceptions and sensations are finer than those of other human beings. Such “seers” are able to see manifestations of force where ordinary people can see nothing. S. W. sees Magnesor as a shining white or bluish vapour which develops when good spirits are near. Connesor is a black

fuming fluid which develops on the appearance of “black” spirits. On the night before the great visions began, the shiny Magnesor vapour spread round her in thick layers, and the good spirits solidified out of it into visible white figures. It was just the same with Connesor. These two forces have their different mediums. S. W. is a Magnesor medium, like the Clairvoyante of Prevorst and Swedenborg. The materialization mediums of the spiritualists are mostly Connesor mediums, since materialization takes place much more easily through Connesor on account of its close connection with the properties of matter. In the summer of 1900, S. W. tried several times to produce a picture of the circles of matter, but she never got beyond vague and incomprehensible hints, and afterwards she spoke of it no more.

Termination of the Disorder

[71] The really interesting and significant séances came to an end with the production of the power system. Even before this, the vitality of the ecstasies had been falling off considerably. Ulrich von Gerbenstein came increasingly to the forefront and filled the séances for hours on end with his childish chatter. The visions which S. W. had in the meantime likewise seem to have lost much of their richness and plasticity of form, for afterwards she was only able to report ecstatic feelings in the presence of good spirits and disagreeable ones in that of bad spirits. Nothing new was produced. In the trance conversations, one could observe a trace of uncertainty, as if she were feeling her way and seeking to make an impression on her audience; there was also an increasing staleness of content. In her outward behaviour, too, there was a marked shyness and uncertainty, so that the impression of wilful deception became ever stronger. The writer therefore soon withdrew from the séances. S. W. experimented later in other circles, and six months after the conclusion of my observations was caught cheating *in flagrante*. She wanted to revive the wavering belief in her supernatural powers by genuinely spiritualistic experiments like apport, etc., and for this purpose concealed in her dress small objects which she threw into the air during the dark séances. After that her role was played out. Since then, eighteen months have gone by, during which I have lost sight of her. But I learn from an observer who

knew her in the early days that now and again she still has rather peculiar states of short duration, when she is very pale and silent and has a fixed glazed look. I have heard nothing of any more visions. She is also said not to take part any longer in spiritualistic séances. S. W. is now an employee in a large business and is by all accounts an industrious and dutiful person who does her work with zeal and skill to the satisfaction of all concerned. According to the report of trustworthy persons, her character has much improved: she has become on the whole quieter, steadier, and more agreeable. No further abnormalities have come to light.

[3. DISCUSSION OF THE CASE]

[72] This case, in spite of its incompleteness, presents a mass of psychological problems whose detailed discussion would far exceed the compass of this paper. We must therefore be content with a mere sketch of the more remarkable phenomena. For the sake of clearer exposition it seems best to discuss the different states under separate heads.

The Waking State

[73] Here the patient shows various peculiarities. As we have seen, she was often absent-minded at school, misread in a peculiar way, was moody, changeable, and inconsequent in her behaviour, now quiet, shy, reserved, now uncommonly lively, noisy, and talkative. She cannot be called unintelligent, yet her narrow-mindedness is sometimes as striking as her isolated moments of intelligence. Her memory is good on the whole, but is often very much impaired by marked distractibility. Thus, despite numerous discussions and readings of Kerner’s *Seherin von Prevorst*, she still does not know after many weeks whether the author is called Koerner or Kerner, or the name of the Clairvoyante, if directly asked. Nevertheless the name “Kerner” appears correctly written when it occasionally turns up in the automatic communications. In general it may be said that there is something extremely immoderate, unsteady, almost protean, in her character. If we discount the psychological fluctuations of character due to puberty, there still remains a pathological residue which

expresses itself in her immoderate reactions and unpredictable, bizarre conduct. One can call this character “déséquilibré” or “unstable.” It gets its specific cast from certain features that must be regarded as hysterical: above all her distractibility and her dreamy nature must be viewed in this light. As Janet[27] maintains, the basis of hysterical anaesthesias is disturbance of attention. He was able to show in youthful hysterics “a striking indifference and lack of attention towards everything to do with the sphere of the perceptions.” A notable instance of this, and one which beautifully illustrates hysterical distractibility, is misreading. The psychology of this process may be thought of somewhat as follows: While reading aloud, a person’s attention slackens and turns towards some other object. Meanwhile the reading continues mechanically, the sense impressions are received as before, but owing to the distraction the excitability of the perceptive centre is reduced, so that the strength of the sense impression is no longer sufficient to fix the attention in such a way as to conduct perception along the verbal-motor route—in other words, to repress all the inflowing associations which immediately ally themselves with any new sense impression. The further psychological mechanism permits of two possible explanations:

(1) The sense impression is received *unconsciously*, i.e., below the threshold of consciousness, owing to the rise of the stimulus threshold in the perceptive centre, and consequently it is not taken up by the conscious attention and conducted along the speech route, but only reaches verbal expression through the mediation of the nearest associations, in this case the dialect expressions for the object.

(2) The sense impression is received *consciously*, but at the moment of entering the speech route it reaches a spot whose excitability is reduced by the distraction. At this point the dialect word is substituted by association for the verbal-motor speech-image and is uttered in place of it. In either case, it is certain that the acoustic distraction fails to correct the error. Which of the two explanations is the right one cannot be determined in our case; probably both approach the truth, for the distractibility appears to be general, affecting more than one of the centres involved in the act of reading aloud.

[74] In our case this symptom has a special value, because we have here a quite elementary automatic phenomenon. It can be called hysterical because in this particular case the state of exhaustion and intoxication with its parallel symptoms can be ruled out. Only in exceptional circumstances does a healthy person allow himself to be so gripped by an object that he fails to correct the errors due to inattention, especially those of the kind described. The frequency with which this happens in the patient points to a considerable restriction of the field of consciousness, seeing that she can control only a minimum of the elementary perceptions simultaneously flowing in upon her. If we wish to define the psychological state of the "psychic shadow side" we might describe it as a sleep- or dream-state according to whether passivity or activity is its dominant feature. A pathological dream-state of rudimentary scope and intensity is certainly present here; its genesis is spontaneous, and dream-states that arise spontaneously and produce automatisms are usually regarded as hysterical. It must be pointed out that instances of misreading were a frequent occurrence in our patient and that for this reason the term "hysterical" is appropriate, because, so far as we know, it is only on the basis of an hysterical constitution that partial sleep- or dream-states occur both frequently and spontaneously.

[75] The automatic substitution of some adjacent association has been studied experimentally by Binet[28] in his hysterical subjects. When he pricked the anaesthetic hand of the patient, she did not feel the prick but thought of "points"; when he moved her fingers, she thought of "sticks" or "columns." Again, when the hand, concealed from the patient's sight by a screen, wrote "Salpêtrière," she saw before her the word "Salpêtrière" in white writing on a black ground. This recalls the experiments of Guinon and Sophie Woltke previously referred to.

[76] We thus find in our patient, at a time when there was nothing to suggest the later phenomena, rudimentary automatisms, fragments of dreaming, which harbour in themselves the possibility that some day more than one association will slip in between the distractibility of her perceptions and consciousness. The misreading also reveals a certain autonomy of the psychic elements; even with a relatively low degree of distractibility, not in any other way striking or suspicious, they develop a

noticeable if slight productivity which approximates to that of the physiological dream. The misreading can therefore be regarded as a prodromal symptom of subsequent events, especially as its psychology is the prototype of the mechanism of somnambulistic dreams, which are in fact nothing but a multiplication and infinite variation of the elementary process we have described above. At the time of my observations I was never able to demonstrate any other rudimentary automatisms of this kind; it seems as if the originally low-grade states of distractibility gradually grew beneath the surface of consciousness into those remarkable somnambulistic attacks and therefore disappeared from the waking state. So far as the development of the patient’s character is concerned, except for a slight increase in maturity no striking change could be noted in the course of observations lasting nearly two years. On the other hand, it is worth mentioning that in the two years since the subsidence (complete cessation?) of the somnambulistic attacks a considerable change of character has taken place. We shall have occasion later on to speak of the significance of this observation.

Semi-Somnambulism

[77] In our account of S. W.’s case, the following condition was indicated by the term “semi-somnambulism”: For some time before and after the actual somnambulistic attack the patient found herself in a state whose most salient feature can best be described as “preoccupation.” She lent only half an ear to the conversation around her, answered absent-mindedly, frequently lost herself in all manner of hallucinations; her face was solemn, her look ecstatic, visionary, ardent. Closer observation revealed a far-reaching alteration of her entire character. She was now grave, dignified; when she spoke, the theme was always an extremely serious one. In this state she could talk so seriously, so forcefully and convincingly, that one almost had to ask oneself: Is this really a girl of 15½? One had the impression that a mature woman was being acted with considerable dramatic talent. The reason for this seriousness, this solemnity of behaviour, was given in the patient’s explanation that at these times she stood on the frontier of this world and the next, and associated just as really with the spirits of the dead as with the living.

And indeed her conversation was about equally divided between answers to objectively real questions and hallucinatory ones. I call this state semi-somnambulistic because it coincides with Richet's own definition:

> Such a person's consciousness appears to persist in its integrity, while all the time highly complex operations are taking place outside consciousness, without the voluntary and conscious ego seeming to be aware of any modification at all. He will have another person within him, acting, thinking, and willing, without his consciousness, that is, his conscious reflecting ego, having the least idea that such is the case.[29]

[78] Binet[30] says of the term "semi-somnambulism":

> This term indicates the relations in which this state stands to genuine somnambulism; and further, it gives us to understand that the somnambulistic life which shows itself during the waking state is overcome and suppressed by the normal consciousness as it reasserts itself.

Automatisms

[79] Semi-somnambulism is characterized by the continuity of consciousness with that of the waking state and by the appearance of various automatisms which point to the activity of a subconscious independent of the conscious self.

[80] Our case shows the following automatic phenomena:

(1) Automatic movements of the table.
(2) Automatic writing.
(3) Hallucinations.

[81] (1) AUTOMATIC MOVEMENTS OF THE TABLE. Before the patient came under my observation she had been influenced by the suggestion of "table-turning," which she first came across as a parlour game. As soon as she entered the circle, communications arrived from members of her family, and she was at once recognized as a medium. I could only ascertain that as soon as her hands were placed on the table the typical movements began. The content of the communications has no further

interest for us. But the automatic character of the act itself merits some discussion, for the objection might very well be made that there was some deliberate pushing or pulling on the part of the patient.

[82] As we know from the investigations of Chevreul, Gley, Lehmann, and others,[31] unconscious motor phenomena are not only a frequent occurrence among hysterical persons and those pathologically inclined in other ways, but can also be induced fairly easily in normal persons who exhibit no other spontaneous automatisms. I have made many experiments on these lines and can fully confirm this observation. In the great majority of cases all that is required is enough patience to put up with an hour or so of quiet waiting. With most subjects motor automatisms will eventually be obtained in more or less high degree if not hindered by counter-suggestions. In a relatively small number of cases the phenomena arise spontaneously, i.e., directly under the influence of verbal suggestion or of some earlier auto-suggestion. In our case the subject was powerfully affected by suggestion. In general, the disposition of the patient is subject to all those laws which also hold good for normal hypnosis. Nevertheless, certain special circumstances must be taken into account which are conditioned by the peculiar nature of the case. It was not a question here of total hypnosis, but of a partial one, limited entirely to the motor area of the arm, like the cerebral anaesthesia produced by magnetic passes for a painful spot in the body. We touch the spot in question, employing verbal suggestion or making use of some existing auto-suggestion, and we use the tactile stimulus which we know acts suggestively to bring about the desired partial hypnosis. In accordance with this procedure refractory subjects can be brought easily enough to an exhibition of automatism. The experimenter intentionally gives the table a slight push, or better, a series of light rhythmical taps. After a while he notices that the oscillations become stronger, that they continue although he has stopped his own intentional movements. The experiment has succeeded, the subject has unsuspectingly taken up the suggestion. Through this procedure far better results are obtained than by verbal suggestion. With very receptive persons and in all those cases where the movement seems to start spontaneously, the intended tremors,[32] which are not of course perceptible to the subject, take over the role of agent

provocateur. In this way persons who by themselves would never achieve automatic movements of the coarser type can sometimes assume unconscious control of the table movements, provided that the tremors are strong enough for the medium to understand their meaning. The medium then takes over the slight oscillations and gives them back considerably strengthened, but rarely at exactly the same moment, mostly a few seconds later, and in this way reveals the agent's conscious or unconscious thought. This simple mechanism may give rise to instances of thought-reading which are quite bewildering at first sight. A very simple experiment that works in many cases even with unpractised persons will serve to illustrate this. The experimenter thinks, say, of the number 4 and then waits, his hands quietly resting on the table, until he feels it making the first move to announce the number thought of. He lifts his hands off the table immediately, and the number will be correctly tilted out. It is advisable in this experiment to stand the table on a soft thick carpet. By paying close attention, the experimenter will occasionally notice a movement of the table that can be represented thus:

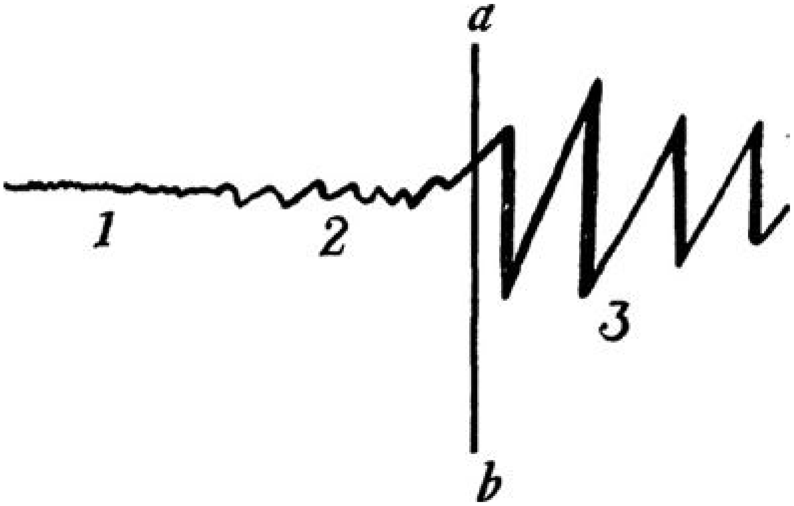

Figure 3

[83] *1*: Intended tremors too slight to be perceived by the subject.

2: Very small but perceptible oscillations of the table which show that the subject is responding to them.

3: The big movements ("tilts") of the table, giving the number 4 that was thought of.

ab denotes the moment when the operator's hands are removed.

[84] This experiment works excellently with well-disposed but inexperienced persons. After a little practice the phenomenon usually disappears, since with practice the number can be read and reproduced directly from the intended movements.[33]

[85] With a responsive medium these intended tremors work in just the same way as the intentional taps in the experiment cited above: they are received, strengthened, and reproduced, though very gently, almost timidly. Even so, they are perceptible and therefore act suggestively as slight tactile stimuli, and with the increase of partial hypnosis they produce the big automatic movements. This experiment illustrates in the clearest way the gradual increase of auto-suggestion. Along the path of this autosuggestion all the automatic motor phenomena develop. How the mental content gradually intrudes into the purely motor sphere scarcely needs explaining after the above discussion. No special suggestion is required to evoke the mental phenomena, since, from the standpoint of the experimenter at least, it was a question of verbal representation from the start. After the first random motor expressions are over, unpractised subjects soon begin reproducing verbal products of their own or the intentions of the experimenter. The intrusion of the mental content can be objectively understood as follows:

[86] Through the gradual increase of auto-suggestion the motor areas of the arm are isolated from consciousness, that is to say, the perception of slight motor impulses is veiled from the mind.[34] The knowledge received via consciousness of a potential mental content produces a collateral excitation in the speech area as the nearest available means to mental formulation. The intention to formulate necessarily affects the motor component[35] of the verbal representation most of all, thus explaining the unconscious overflow of speech impulses into the motor area,[36] and conversely the gradual penetration of partial hypnosis into the speech area.

[87] In numerous experiments with beginners, I have noticed, usually at the start of the mental phenomena, a relatively large number of completely meaningless words, often only senseless jumbles of letters.

Later all sorts of absurdities are produced, words or whole sentences with the letters transposed all higgledy-piggledy or arranged in reverse order, like mirror-writing. The appearance of a letter or word brings a new suggestion; involuntarily some kind of association tacks on to it and is then realized. Curiously enough, these are not as a rule conscious associations but quite unexpected ones. This would seem to indicate that a considerable part of the speech area is already hypnotically isolated. The recognition of this automatism again forms a fruitful suggestion, since at this point a feeling of strangeness invariably arises, if it was not already present in the pure motor automatism. The question "Who is doing this?" "Who is speaking?" acts as a suggestion for synthesizing the unconscious personality, which as a rule is not long in coming. Some name or other presents itself, usually one charged with emotion, and the automatic splitting of the personality is accomplished. How haphazard and precarious this synthesis is at first can be seen from the following reports from the literature.

[88] Myers gives the following interesting observation of a Mr. A., a member of the Society for Psychical Research, who was experimenting on himself with automatic writing:

[89] 3RD DAY

What is man? — *Tefi hasl esble lies*.
Is that an anagram? — *Yes*.
How many words does it contain? — *Five*.
What is the first word? — *See*.
What is the second word? — *Eeeee*.
SEE? Shall I interpret it myself? — *Try to!*

[90] Mr. A. found this solution: "The life is less able." He was astonished at this intellectual pronouncement, which seemed to him to prove the existence of an intelligence independent of his own. He therefore went on to ask:

Who are you? — *Clelia*.
Are you a woman? — *Yes*.
Have you lived on earth? — *No*.
Will you come to life? — *Yes*.
When? — *In six years*.

Why are you conversing with me? — *E if Clelia el*.

Mr. A. interpreted this answer as: “I Clelia feel.”

[91]

4TH DAY

Am I the one who asks questions? — *Yes*.

Is Clelia there?— *No*.

Who is here then? — *Nobody*.

Does Clelia exist at all?— *No*.

Then with whom was I speaking yesterday? — *With nobody*.[37]

[92] Janet conducted the following conversation with the subconscious of Lucie, who, meanwhile, was engaged in conversation with another observer:

[Janet asks:] Do you hear me? [Lucie answers, in automatic writing:] *No*.

But one has to hear in order to answer. — *Absolutely*.

Then how *do* you do it? — *I don’t know*.

There must be someone who hears me. — *Yes*.

Who is it? — *Somebody besides Lucie*.

All right. Somebody else. Shall we give the other person a name? — *No*.

Yes, it will be more convenient. — *All right. Adrienne*.

Well, Adrienne, do you hear me? — *Yes*.[38]

[93] One can see from these extracts how the unconscious personality builds itself up: it owes its existence simply to suggestive questions which strike an answering chord in the medium’s own disposition. This disposition can be explained by the disaggregation of psychic complexes, and the feeling of strangeness evoked by these automatisms assists the process as soon as conscious attention is directed to the automatic act. Binet remarks on this experiment of Janet’s: “Nevertheless it should be carefully noted that if the personality of ‘Adrienne’ could be created, it was because the suggestion encountered a *psychological possibility;* in other words, disaggregated phenomena were existing there apart from the

normal consciousness of the subject."[39] The individualization of the subconscious is always a great step forward and has enormous suggestive influence on further development of the automatisms.[40] The formation of unconscious personalities in our case must also be regarded in this light.

[94] The objection that the table-turning was "simulated" may well be abandoned when one considers the phenomenon of thought-reading from intended tremors, of which the patient gave ample proof. Rapid, conscious thought-reading requires at the very least an extraordinary amount of practice, and this the patient demonstrably lacked. Whole conversations can be carried on by means of these tremors, as happened in our case. In the same way the suggestibility of the subconscious can be demonstrated objectively if, for instance, the operator concentrates on the thought: "The medium's hand shall no longer move the table or the glass," and at once, contrary to all expectation, and to the liveliest astonishment of the subject, the table is immobilized. Naturally all kinds of other suggestions can be realized too, provided that their innervation does not exceed the area of partial hypnosis (which proves at the same time the partial nature of the hypnosis). Hence suggestions aimed at the legs or the other arm will not work.

[95] The table-turning was not an automatism confined exclusively to the patient's semi-somnambulism. On the contrary it occurred in its most pronounced form in the waking state, and in most cases then passed over into semi-somnambulism, whose onset was generally announced by hallucinations, as at the first séance.

[96] (2) AUTOMATIC WRITING. Another automatic phenomenon, which from the first corresponds to a higher degree of partial hypnosis, is automatic writing. It is, at least in my experience, much rarer and much more difficult to produce than table-turning. Here again it is a question of a primary suggestion, directed to the conscious mind when sensibility is retained, and to the unconscious when it is extinct. The suggestion, however, is not a simple one, since it already contains an intellectual element: "to write" means "to write something." This special property of the suggestion, going beyond the purely motor sphere, often confuses the subject and gives rise, to counter-suggestions which prevent the

appearance of automatisms. However, I have noticed in a few cases that the suggestion is realized despite its comparative boldness (it is after all directed to the waking consciousness of a so-called normal person!), but that it does so in a peculiar way, by putting only the purely motor part of the central nervous system under hypnosis, and that the deeper hypnosis is then obtained from the motor phenomenon by auto-suggestion, as in the procedure for table-turning described above. The subject,[41] holding a pencil in his hand, is purposely engaged in conversation to distract his attention from writing. The hand thereupon starts to move, making a number of strokes and zigzag lines at first, or else a simple line.

Figure 4

It sometimes happens that the pencil does not touch the paper at all but writes in the air. These movements must be regarded as purely motor phenomena corresponding to the expression of the motor element in the idea of "writing." They are somewhat rare; usually single letters are written right off, and what was said above of table-turning is true here of their combination into words and sentences. Now and then true mirror-writing is observed. In the majority of cases, and perhaps in all experiments with beginners who are not under some special suggestion, the automatic writing is that of the subject. Occasionally its character may be greatly changed,[42] but this is secondary, and is always a symptom of the synthesis of a subconscious personality. As already stated, the automatic writing of our patient never came to very much. The experiments were carried out in the dark, and in most cases she passed over into semi-somnambulism or ecstasy. So the automatic writing had the same result as the preliminary table-turning.

[97] (3) HALLUCINATIONS. The manner of transition to somnambulism in the second séance is of psychological significance. As reported, the automatic phenomena were in full swing when darkness descended. The interesting event in the preceding séance was the brusque interruption of a

communication from the grandfather, which became the starting-point for various discussions among members of the circle. These two factors, darkness and a remarkable occurrence, seem to have caused a rapid deepening of hypnosis, which enabled the hallucinations to develop. The psychological mechanism of this process seems to be as follows: The influence of darkness on suggestibility, particularly in regard to the sense organs, is well known.[43] Binet states that it has a special influence on hysterical subjects, producing immediate drowsiness.[44] As may be assumed from the foregoing explanations, the patient was in a state of partial hypnosis, and furthermore a subconscious personality having the closest ties with the speech area had already constituted itself. The automatic expression of this personality was interrupted in the most unexpected way by a new person whose existence no one suspected. Whence came this split? Obviously the patient had entertained the liveliest expectations about this first séance. Any reminiscences she had of me and my family had probably grouped themselves around this feeling of expectation, and they suddenly came to light when the automatic expression was at its climax. The fact that it was my grandfather and no one else—not, for instance, my dead father, who, as the patient knew, was closer to me than my grandfather, whom I had never known—may suggest where the origin of this new person is to be sought. It was probably a dissociation from the already existing personality, and this split-off part seized upon the nearest available material for its expression, namely the associations concerning myself. Whether this offers a parallel to the results of Freud's dream investigations[45] must remain unanswered, for we have no means of judging how far the emotion in question may be considered "repressed." From the brusque intervention of the new personality we may conclude that the patient's imaginings were extremely vivid, with a correspondingly intense expectation which a certain maidenly modesty and embarrassment sought perhaps to overcome. At any rate this event reminds us vividly of the way dreams suddenly present to consciousness, in more or less transparent symbolism, things one has never admitted to oneself clearly and openly. We do not know when the splitting off of the new personality occurred, whether it had been slowly preparing in the unconscious, or whether it only came about during the séance. In any case it meant a considerable increase in the extent of the unconscious area rendered accessible by hypnosis. At the same time this event, in view of the impression it made on the waking consciousness of the patient, must be regarded as powerfully suggestive, for the perception of the unexpected intervention of a new personality was bound to increase still further the feeling of strangeness aroused by the automatism, and would naturally suggest the thought that an independent spirit was making itself known. From this followed the very understandable association that it might be possible to see this spirit.

[98] The situation that ensued at the second séance can be explained by the coincidence of this energizing suggestion with the heightened suggestibility occasioned by the darkness. The hypnosis, and with it the chain of split-off ideas, breaks through into the visual sphere; the expression of the unconscious, hitherto purely motor, is objectified (in accordance with the specific energy of the newly created system) in the form of visual images having the character of an hallucination—not as a mere accompaniment of the verbal automatism but as a direct substitute function. The explanation of the unexpected situation that arose in the first séance, at the time quite inexplicable, is no longer given in words, but as an allegorical vision. The proposition “they do not hate one another, but are friends” is expressed in a picture of the two grandfathers arm-in-arm. We frequently come across such things in somnambulism: the thinking of somnambulists proceeds in plastic images which constantly break through into this or that sensory sphere and are objectified as hallucinations. The thought process sinks into the subconscious and only its final terms reach consciousness directly as hallucinations or as vivid and sensuously coloured ideas. In our case the same thing occurred as with the patient whose anaesthetic hand Binet pricked nine times, making her think vividly of the number 9; or Flournoy’s Hélène Smith, who, on being asked in her shop about a certain pattern, suddenly saw before her the figure 18, eight to ten inches high, representing the number of days the pattern had been on loan.[46] The question arises as to why the automatism broke through in the visual

sphere and not in the acoustic. There are several reasons for this choice of the visual:

[99] (*a*) The patient was not gifted acoustically; she was for instance very unmusical.

(*b*) There was no silence (to correspond with the darkness) which might have favoured the occurrence of auditory hallucinations, for we were talking all the time.

(c) The heightened conviction of the near presence of spirits, owing to the feeling of strangeness evoked by the automatism, could easily lead to the idea that it might be possible to see a spirit, thus causing a slight excitation of the visual sphere.

(*d*) The entoptic phenomena in the darkness favoured the appearance of hallucinations.

[100] The reasons given in (*c*) and (*d*) are of decisive importance for the appearance of hallucinations. The entoptic phenomena in this case play the same role in producing automatisms by auto-suggestion as do the slight tactile stimuli during hypnosis of the motor centres. As reported, the patient *saw* sparks before passing into the first hallucinatory twilight state at the first séance. Obviously attention was already at high pitch and directed to visual perceptions, so that the light sensations of the retina, usually very weak, were seen with great intensity. The part played by entoptic perceptions of light in the production of hallucinations deserves closer scrutiny. Schüle says: “The swarm of lights and colours that excite and activate the nocturnal field of vision in the darkness supplies the material for the fantastic figures seen in the air before going to sleep.”[47] As we know, we never see absolute darkness, always a few patches of the dark field are dully illuminated; flecks of light bob up here and there and combine into all sorts of shapes, and it only needs a moderately active imagination to form out of them, as one does out of clouds, certain figures known to oneself personally. As one falls asleep, one’s fading power of judgment leaves the imagination free to construct more and more vivid forms. “Instead of the spots of light, the haziness and changing colours of the dark visual field, outlines of definite objects begin to appear.”[48] Hypnagogic hallucinations arise in this way. Naturally

the chief share falls to the imagination, which is why highly imaginative people are particularly subject to them.[49] The "hypnopompic" hallucinations described by Myers are essentially the same as the hypnagogic ones.

[101] It is very probable that hypnagogic images are identical with the dream-images of normal sleep, or that they form their visual foundation. Maury[50] has proved by self-observation that the images which floated round him hypnagogically were also the objects of the dreams that followed. Ladd[51] showed the same thing even more convincingly. With practice he succeeded in waking himself up two to five minutes after falling asleep. Each time he noticed that the bright figures dancing before the retina formed as it were the outlines of the images just dreamed of. He even supposes that practically all visual dreams derive their formal elements from the light sensations of the retina. In our case the situation favoured the development of a fantastic interpretation. Also, we must not underrate the influence of the tense expectation which caused the dull light sensations of the retina to appear with increased intensity.[52] The development of retinal phenomena then followed in accordance with the predominant ideas. Hallucinations have been observed to arise in this way with other visionaries: Joan of Arc saw first a cloud of light,[53] then out of it, a little later, stepped St. Michael, St. Catharine, and St. Margaret. Swedenborg saw nothing for a whole hour but luminous spheres and brilliant flames.[54] All the time he felt a tremendous change going on in his brain, which seemed to him like a "release of light." An hour afterwards he suddenly saw real figures whom he took to be angels and spirits. The sun vision of Benvenuto Cellini in Sant' Angelo probably belongs to the same category.[55] A student who often saw apparitions said: "When these apparitions come, I see at first only single masses of light and hear at the same time a dull roaring in my ears. But after a bit these outlines turn into distinct figures."[56] The hallucinations arise in quite the classical way with Flournoy's Hélène Smith. I cite the relevant passages from his report:

[102] *March 18.* Attempt to experiment in the darkness.… Mlle. Smith sees a balloon, now luminous, now becoming dark.

[103] *March* 25.… Mlle. Smith begins to distinguish vague gleams with long white streamers moving from the floor to the ceiling, and then a magnificent star, which in the darkness appears to her alone throughout the whole séance.

[104] *April 1.* Mlle. Smith is very much agitated; she has fits of shivering, is very cold. She is very restless, and sees suddenly, hovering above the table, a grinning, very ugly face, with long red hair. Afterwards she sees a magnificent bouquet of roses of different hues.… Suddenly she sees a small snake come out from underneath the bouquet; it rises up gently, smells the flowers, looks at them …[57]

[105] Concerning the origin of her Mars visions, Hélène Smith said: “The red light continues about me, and I find myself surrounded by extraordinary flowers.…”[58]

[106] At all times the complex hallucinations of visionaries have occupied a special place in scientific criticism. Thus, quite early, Macario[59] distinguished them as “intuitive” hallucinations from ordinary hallucinations, saying that they occur in persons of lively mind, deep understanding, and high nervous excitability. Hecker expresses himself in a similar manner but even more enthusiastically. He supposes their conditioning factor to be the “congenitally high development of the psychic organ, which through its spontaneous activity calls the life of the imagination into free and nimble play.”[60] These hallucinations are “harbingers and also signs of an immense spiritual power.” A vision is actually “a higher excitation which adapts itself harmoniously to the most perfect health of mind and body.” Complex hallucinations do not belong to the waking state but occur as a rule in a state of partial waking: the visionary is sunk in his vision to the point of complete absorption. Flournoy, too, was always able to establish “a certain degree of obnubilation” during the visions of Hélène Smith.[61] In our case the vision is complicated by a sleeping state whose peculiarities we shall discuss below.

The Change in Character

[107] The most striking feature of the “second state” is the change in character. There are several cases in the literature which show this symptom of spontaneous change in the character of a person. The first to be made known in a scientific journal was that of Mary Reynolds, published by Weir Mitchell.[62] This was the case of a young woman living in Pennsylvania in 1811. After a deep sleep of about twenty hours, she had totally forgotten her entire past and everything she had ever learnt; even the words she spoke had lost their meaning. She no longer knew her relatives. Slowly she re-learnt to read and write, but her writing now was from right to left. More striking still was the change in her character. “Instead of being melancholy she was now cheerful to extremity. Instead of being reserved she was buoyant and social. Formerly taciturn and retiring, she was now merry and jocose. Her disposition was totally and absolutely changed.”[63]

[108] In this state she gave up entirely her former secluded life and liked to set out on adventurous expeditions unarmed, through woods and mountains, on foot and on horseback. On one of these expeditions she encountered a large black bear, which she took for a pig. The bear stood up on his hind legs and gnashed his teeth at her. As she could not induce her horse to go any further, she went up to the bear with an ordinary stick and hit him until he took to flight. Five weeks later, after a deep sleep, she returned to her earlier state with amnesia for the interval. These states alternated for about sixteen years. But the last twenty-five years of her life Mary Reynolds passed exclusively in the second state.

[109] Schroeder van der Kolk[64] reports the following case: The patient became ill at the age of sixteen with a periodic amnesia after a previous long illness of three years. Sometimes in the morning after waking she fell into a peculiar choreic state, during which she made rhythmical beating movements with her arms. Throughout the day she would behave in a childish, silly way, as if she had lost all her educated faculties. When normal she was very intelligent, well-read, spoke excellent French. In the second state she began to speak French faultily. On the second day she was always normal again. The two states were completely separated by amnesia.[65]

[110] Höfelt[66] reports on a case of spontaneous somnambulism in a girl who in her normal state was submissive and modest, but in somnambulism was impertinent, rude, and violent. Azam's Felida[67] was in her normal state depressed, inhibited, timid, and in the second state lively, confident, enterprising to recklessness. The second state gradually became the dominant one and finally supplanted the first to such an extent that the patient called her normal states, which now lasted only a short time, her "crises." The amnesic attacks had begun at the age of 14½. In time the second state became more moderate, and there was a certain approximation in the character of the two states. A very fine example of change in character is the case worked out by Camuset, Ribot, Legrand du Saule, Richer, and Voisin and put together by Bourru and Burot.[68] It is that of Louis V., a case of severe male hysteria, with an amnesic alternating character. In the first state he was rude, cheeky, querulous, greedy, thievish, inconsiderate. In the second state he showed an agreeable, sympathetic character and was industrious, docile, and obedient. The amnesic change in character has been put to literary use by Paul Lindau[69] in his play *Der Andere*. A case that parallels Lindau's criminalistic public prosecutor is reported on by Rieger.[70] The subconscious personalities of Janet's Lucie and Léonie,[71] or of Morton Prince's patient,[72] can also be regarded as parallels of our case, though these were artificial therapeutic products whose importance lies rather in the domain of dissociated consciousness and memory.

[111] In all these cases the second state is separated from the first by an amnesic split, and the change in character is accompanied by a break in the continuity of consciousness. In our case there is no amnesic disturbance whatever; the transition from the first to the second state is quite gradual, continuity of consciousness is preserved, so that the patient carries over into the waking state everything she has experienced of the otherwise unknown regions of the unconscious during hallucinations in the second state.

[112] Periodic changes in personality without an amnesic split are found in cyclic insanity, but they also occur as a rare phenomenon in hysteria, as Renaudin's case shows.[73] A young man, whose behaviour had always

been exemplary, suddenly began to display the worst tendencies. No symptoms of insanity were observed, but on the other hand the whole surface of his body was found to be anaesthetic. This state was periodic, and, in the same way, the patient’s character was subject to fluctuations. As soon as the anaesthesia disappeared he became manageable and friendly. The moment it returned he was dominated by the worst impulses, including even the lust for murder.

[113] If we remember that our patient’s age at the beginning of the disturbances was 15½, i.e., that the age of puberty had just been reached, we must suppose that there was some connection between these disturbances and the physiological changes of character at puberty.

At this period of life there appears in the consciousness of the individual a new group of sensations together with the ideas and feelings arising therefrom. This continual pressure of unaccustomed mental states, which constantly make themselves felt because their cause is constantly at work, and which are co-ordinated with one another because they spring from one and the same source, must in the end bring about far-reaching changes in the constitution of the ego.[74]

We all know the fitful moods, the confused, new, powerful feelings, the tendency to romantic ideas, to exalted religiosity and mysticism, side by side with relapses into childishness, which give the adolescent his peculiar character. At this period he is making his first clumsy attempts at independence in every direction; for the first time he uses for his own purposes all that family and school have inculcated into him in childhood; he conceives ideals, constructs lofty plans for the future, lives in dreams whose main content is ambition and self-complacency. All this is physiological. The puberty of a psychopath is a serious crisis. Not only do the psychophysical changes run an exceedingly stormy course, but features of an inherited degenerate character, which do not appear in the child at all or only sporadically, now become fixed. In explaining our case we are bound to consider a specifically pubertal disturbance. The reasons for this will appear from a more detailed study of her second personality. For the sake of brevity we shall call this second personality Ivenes, as the patient herself christened her higher ego.

[114] Ivenes is the direct continuation of her everyday ego. She comprises its whole conscious content. In the semi-somnambulist state her relation to the external world is analogous to that of the waking state—that is to say, she is influenced by recurrent hallucinations, but no more than persons who are subject to non-confusional psychotic hallucinations. The continuity of Ivenes obviously extends to the hysterical attacks as well, when she enacts dramatic scenes, has visionary experiences, etc. During the actual attack she is usually isolated from the external world, does not notice what is going on around her, does not know that she is talking loudly, etc. But she has no amnesia for the dream-content of the attack. Nor is there always amnesia for her motor expressions and for the changes in her surroundings. That this is dependent on the degree of somnambulistic stupor and on the partial paralysis of individual sense organs is proved by the occasion when the patient did not notice me, despite the fact that her eyes were open and that she probably saw the others, but only perceived my presence when I spoke to her. This is a case of so-called *systematic anaesthesia* (negative hallucination), which is frequently observed among hysterics.

[115] Flournoy,[75] for instance, reports of Hélène Smith that during the séances she suddenly ceased to see those taking part, although she still heard their voices and felt their touch; or that she suddenly stopped hearing, although she saw the speakers moving their lips, etc.

[116] Just as Ivenes is a continuation of the waking ego, so she carries over her whole conscious content into the waking state. This remarkable behaviour argues strongly against any analogy with cases of double consciousness. The characteristics reported of Ivenes contrast favourably with those of the patient; she is the calmer, more composed personality, and her pleasing modesty and reserve, her more uniform intelligence, her confident way of talking, may be regarded as an improvement on the patient's whole being; thus far there is some resemblance to Janet's Léonie. But it is no more than a resemblance. They are divided by a deep psychological difference, quite apart from the question of amnesia. Léonie II is the healthier, the more normal; she has regained her natural capacities, she represents the temporary amelioration of a chronic condition of hysteria. Ivenes gives more the impression of an artificial

product; she is more contrived, and despite all her excellent points she strikes one as playing a part superlatively well. Her world-weariness, her longing for the Beyond, are not mere piety but the attributes of saintliness. Ivenes is no longer quite human, she is a mystic being who only half belongs to the world of reality. Her mournful features, her suffering resignation, her mysterious fate all lead us to the historical prototype of Ivenes: Justinus Kerner's Clairvoyante of Prevorst. I assume that the content of Kerner's book is generally known, so I omit references to the features they have in common. Ivenes, however, is not just a copy of the Clairvoyante; the latter is simply a sketch for an original. The patient pours her own soul into the role of the Clairvoyante, seeking to create out of it an ideal of virtue and perfection; she anticipates her own future and embodies in Ivenes what she wishes to be in twenty years' time—the assured, influential, wise, gracious, pious lady. In the construction of the second personality lies the deep-seated difference between Léonie II and Ivenes. Both are psychogenic, but whereas Léonie I obtains in Léonie II what properly belongs to her, the patient builds up a personality beyond herself. One cannot say that she deludes herself into the higher ideal state, rather she dreams herself into it.[76]

[117] The realization of this dream is very reminiscent of the psychology of the pathological swindler. Delbrück[77] and Forel[78] have pointed out the importance of auto-suggestion in the development of pathological cheating and pathological daydreaming. Pick[79] regards intense auto-suggestion as the first symptom of hysterical dreamers which makes the realization of "daydreams" possible. One of Pick's patients dreamt herself into a morally dangerous situation and finally carried out an attempt at rape on herself by lying naked on the floor and tying herself to the table and chairs. The patients may create some dramatic personage with whom they enter into correspondence by letter, as in Bohn's case,[80] where the patient dreamt herself into an engagement with a completely imaginary lawyer in Nice, from whom she received letters which she had written herself in disguised handwriting. This pathological dreaming, with its auto-suggestive falsifications of memory sometimes amounting to actual delusions and hallucinations, is also found in the lives of many saints.[81] It is only a step from dreamy ideas with a strong sensuous colouring to

complex hallucinations proper.[82] For instance, in Pick's first case, one can see how the patient, who imagined she was the Empress Elizabeth, gradually lost herself in her reveries to such an extent that her condition must be regarded as a true twilight state. Later it passed over into an hysterical delirium in which her dream fantasies became typical hallucinations. The pathological liar who lets himself be swept away by his fantasies behaves exactly like a child who loses himself in the game he is playing,[83] or like an actor who surrenders completely to his part. There is no fundamental distinction between this and the somnambulistic dissociation of the personality, but only a difference of degree based on the intensity of the primary auto-suggestibility or disaggregation of the psychic elements. The more consciousness becomes dissociated the greater becomes the plasticity of the dream situations, and the less, too, the amount of conscious lying and of consciousness in general. This state of being carried away by one's interest in the object is what Freud calls hysterical identification. For instance, Erler's patient,[84] a severe hysteric, had hypnagogic visions of little riders made of paper, who so took possession of her imagination that she had the feeling of being herself one of them. Much the same sort of thing normally happens to us in dreams, when we cannot help thinking "hysterically."[85] Complete surrender to the interesting idea explains the wonderful naturalness of these pseudological or somnambulistic performances, which is quite beyond the reach of conscious acting. The less the waking consciousness intervenes with its reflection and calculation, the more certain and convincing becomes the objectivation of the dream.[86]

[118] Our case has still another analogy with *pseudologia phantastica:* the development of fantasies during the attacks. Many cases are known in the literature of fits of pathological lying, accompanied by various hysteriform complaints.[87] Our patient develops her fantasy systems exclusively during the attack. In her normal state she is quite incapable of thinking out new ideas or explanations; she must either put herself into the somnambulistic state or await its spontaneous appearance. This exhausts the affinities with *pseudologia phantastica* and pathological dreaming.

[119] Our patient differs essentially from pathological dreamers in that it could never be proved that her reveries had previously been the object of her daily interests; her dreams came up explosively, suddenly bursting forth with amazing completeness from the darkness of the unconscious. The same thing happened with Flournoy's Hélène Smith. At several points, however, it is possible in our case to demonstrate the link with perceptions in the normal state [see next par.], so it seems probable that the roots of those dreams were originally feeling-toned ideas which only occupied her waking consciousness for a short time.[88] We must suppose that hysterical forgetfulness[89] plays a not inconsiderable role in the origin of such dreams: many ideas which, in themselves, would be worth preserving in consciousness, sink below the threshold, associated trains of thought get lost and, thanks to psychic dissociation, go on working in the unconscious. We meet the same process again in the genesis of our own dreams.[90] The apparently sudden and unexpected reveries of the patient can be explained in this way. The total submersion of the conscious personality in the dream role is also the indirect cause of the development of simultaneous automatisms:

> A second condition may also occasion the division of consciousness. It is not an alteration of sensibility, but it is rather a peculiar attitude of the mind—the concentration of attention on a single thing. The result of this state of concentration is that the mind is absorbed to the exclusion of other things, and to such a degree insensible that the way is opened for automatic actions; and these actions, becoming more complicated, as in the preceding case, may assume a psychic character and constitute intelligences of a parasitic kind, existing side by side with the normal personality, which is not aware of them.[91]

[120] Our patient's "romances" throw a most significant light on the subjective roots of her dreams. They swarm with open and secret love-affairs, with illegitimate births and other sexual innuendoes. The hub of all these ambiguous stories is a lady whom she dislikes, and who gradually turns into her polar opposite, for whereas Ivenes is the pinnacle of virtue this lady is a sink of iniquity. But the patient's reincarnation theory, in which she appears as the ancestral mother of countless thousands, springs, in all of its naïve nakedness, straight from an

exuberant fantasy which is so very characteristic of the puberty period. It is the woman’s premonition of sexual feeling, the dream of fertility, that has created these monstrous ideas in the patient. We shall not be wrong if we seek the main cause of this curious clinical picture in her budding sexuality. From this point of view the whole essence of Ivenes and her enormous family is nothing but a dream of sexual wish-fulfilment, which differs from the dream of a night only in that it is spread over months and years.

[*Nature of the Somnambulistic Attacks*]

[121] So far there is one point in S. W.’s history that has not been discussed, and that is the nature of her attacks. In the second séance she was suddenly seized with a sort of fainting-fit, from which she awoke with a recollection of various hallucinations. According to her own statement, she had not lost consciousness for a moment. Judging from the outward symptoms and course of these attacks, one is inclined to think of narcolepsy or lethargy, of the kind described, for instance, by Loewenfeld. This is the more plausible since we know that one member of her family—the grandmother—had once had an attack of lethargy. So it is conceivable that our patient inherited the lethargic disposition (Loewenfeld). One often observes hysterical fits of convulsions at spiritualistic séances. Our patient never showed any symptoms of convulsions, but instead she had those peculiar sleeping states. Aetiologically, two elements must be considered for the first attack:

(1) The influence of hypnosis.

(2) Psychic excitation.

[122] (1) INFLUENCE OF PARTIAL HYPNOSIS. Janet observed that subconscious automatisms have a hypnotic influence and can bring about complete somnambulism.[92] He made the following experiment: While the patient, who was fully awake, was engaged in conversation by a second observer, Janet stationed himself behind her and by means of whispered suggestions made her unconsciously move her hand, write, and answer questions by signs. Suddenly the patient broke off the conversation, turned round, and with supraliminal consciousness continued the

previously subconscious talk with Janet. She had fallen into hypnotic somnambulism.[93] In this example we see a process similar to our case. But, for certain reasons to be discussed later, the sleeping state cannot be regarded as hypnotic. We therefore come to the question of:

[123] (2) PSYCHIC EXCITATION. It is reported that the first time Bettina Brentano met Goethe, she suddenly fell asleep on his knee.[94] Ecstatic sleep in the midst of extreme torture, the so-called "witch's sleep," is a well-known phenomenon in the annals of witchcraft.[95]

[124] With susceptible subjects, comparatively small stimuli are enough to induce somnambulistic states. For example, a sensitive lady had to have a splinter cut out of her finger. Without any kind of bodily change she suddenly saw herself sitting beside a brook in a beautiful meadow, plucking flowers. This condition lasted all through the minor operation and then vanished without having any special after-effects.[96]

[125] Loewenfeld observed the unintentional induction of hysterical lethargy by hypnosis.[97] Our case has certain resemblances to hysterical lethargy as described by Loewenfeld:[98] superficial respiration, lowering of the pulse, corpse-like pallor of the face, also peculiar feelings of dying and thoughts of death.[99] Retention of one or more senses is no argument against lethargy: for instance in certain cases of apparent death the sense of hearing remains.[100] In Bonamaison's case,[101] not only was the sense of touch retained, but the senses of hearing and smell were sharpened. Hallucinations and loud speaking of hallucinatory persons are also met with in lethargy.[102] As a rule there is total amnesia for the lethargic interval. Loewenfeld's case D. had a vague memory afterwards,[103] and in Bonamaison's case there was no amnesia. Lethargic patients do not prove accessible to the usual stimuli for rousing them, but Loewenfeld succeeded, with his patient St., in changing the lethargy into hypnosis by means of mesmeric passes, thus establishing contact with the rest of her consciousness during the attack.[104] Our patient proved at first absolutely inaccessible during lethargy; later she started to speak spontaneously, was indistractible when her somnambulistic ego was speaking, but distractible when the speaker was one of her automatic personalities. In the latter case, it seems probable that the hypnotic effect of the automatisms

succeeded in achieving a partial transformation of the lethargy into hypnosis. When we consider Loewenfeld’s view that the lethargic disposition must not be “identified outright with the peculiar behaviour of the nervous apparatus in hysteria,” then the assumption that this disposition was due to family heredity becomes fairly probable. The clinical picture is much complicated by these attacks.

[126] So far we have seen that the patient’s ego-consciousness was identical in all states. We have discussed two secondary complexes of consciousness and followed them into the somnambulistic attack, where, owing to loss of motor expression, they appeared to the patient in the second séance as a vision of the two grandfathers. These complexes completely disappeared from view during the attacks that followed, but on the other hand they developed an all the more intense activity during the twilight state, in the form of visions. It seems that numerous secondary sequences of ideas must have split off quite early from the primary unconscious personality, for soon after the first two séances “spirits” appeared by the dozen. The names were inexhaustible in their variety, but the differences between the various personalities were exhausted very quickly, and it became apparent that they could all be classified under two types, the *serio-religious* and the *gay-hilarious*. It was really only a question of two different subconscious personalities appearing under various names, which had however no essential significance. The older type, the grandfather, who had started the automatisms off in the first place, was also the first to make use of the twilight state. I cannot remember any suggestion that might have given rise to the automatic speaking. According to our previous explanations, the attack can in these circumstances be thought of as a partial self-hypnosis. The ego-consciousness which remains over and, as a result of its isolation from the external world, occupies itself entirely with its hallucinations, is all that is left of the waking consciousness. Thus the automatism has a wide field for its activity. The autonomy of the individual centres, which we found to be present in the patient from the beginning, makes the act of automatic speaking more understandable. Dreamers, too, occasionally talk in their sleep, and people in the waking state sometimes accompany intense thought with unconscious

whispering.[105] The peculiar movements of the speech muscles are worth noting. They have also been observed in other somnambulists.[106] These clumsy attempts can be directly paralleled by the unintelligent and clumsy movements of the table or glass; in all probability they correspond to the preliminary expression of the motor components of an idea, or they correspond to an excitation limited to the motor centres and not yet subordinated to a higher system. I do not know whether anything of the sort occurs with people who talk in their dreams, but it has been observed in hypnotized persons.[107]

[127] Since the convenient medium of speech was used as the means of communication, it made the study of the subconscious personalities considerably easier. Their intellectual range was relatively narrow. Their knowledge comprised all that the patient knew in her waking state, plus a few incidental details such as the birthdays of unknown persons who were dead, etc. The source of this information is rather obscure, since the patient did not know how she could have procured knowledge of these facts in the ordinary way. They were cryptomnesias, but are too insignificant to deserve more detailed mention. The two subconscious personalities had a very meagre intelligence; they produced almost nothing but banalities. The interesting thing is their relation to the ego-consciousness of the patient in the somnambulistic state. They were well informed about everything that took place during the ecstasies and occasionally gave an exact report, like a running commentary.[108] But they had only a very superficial knowledge of the patient's fantasies; they did not understand them and were unable to answer a single question on this subject correctly; their stereotyped reply was "Ask Ivenes." This observation reveals a dualism in the nature of the subconscious personalities which is rather difficult to explain; for the grandfather, who manifests himself through automatic speech, also appears to Ivenes, and according to her own statement "knew all her thoughts." How is it that when the grandfather speaks through the mouth of the patient he knows nothing about the very things he teaches Ivenes in the ecstasies?

[128] Let us go back to what we said at the first appearance of the hallucinations [par. 98]. There we described the vision of the grandfathers as an irruption of hypnosis into the visual sphere. That irruption did not

lead to a “normal” hypnosis but to “hystero-hypnosis”; in other words, the simple hypnosis was complicated by an hysterical attack.

[129] It is not a rare occurrence for normal hypnosis to be disturbed, or rather to be replaced, by the unexpected appearance of hysterical somnambulism; the hypnotist in many cases then loses rapport with the patient. In our case the automatism arising in the motor area plays the part of the hypnotist, and the suggestions emanating from it (objectively described as autosuggestions) hypnotize the neighbouring areas which have grown susceptible. But the moment the hypnosis affects the visual sphere the hysterical attack intervenes, and this, as we have remarked, effects a very profound change over large portions of the psychic area. We must picture the automatism as standing in the same relation to the attack as the hypnotist to a pathological hypnosis: it loses its influence on the subsequent development of the situation. The hallucinatory appearance of the hypnotic personality, or of the suggested idea, may be regarded as its last effect on the personality of the somnambulist. Thereafter the hypnotist becomes a mere figure with whom the somnambulistic personality engages autonomously; he can only just make out what is going on, but can no longer condition the content of the attack. The autonomous ego-complex—in this case Ivenes—now has the upper hand, and she groups her own mental products around the personality of her hypnotist, the grandfather, now diminished to a mere image. In this way we are able to understand the dualism in the nature of the grandfather. *Grandfather I, who speaks directly to those present, is a totally different person and a mere spectator of his double, Grandfather II, who appears as Ivenes’ teacher*. Grandfather I maintains energetically that both are one and the same person, that Grandfather I has all the knowledge which Grandfather II possesses and is only prevented from making it public because of language difficulties. (The patient herself was naturally not conscious of this split, but took both to be the same person.) On closer inspection, however, Grandfather I is not altogether wrong, and he can appeal to an observation which apparently confirms the identity of I and II, i.e., the fact that they are never both present together, When I is speaking automatically, II is not present, and Ivenes remarks on his absence. Similarly, during her ecstasies, when she is with II, she cannot

say where I is, or she only learns on returning from her journeys that he has been guarding her body in the meantime. Conversely, the grandfather never speaks when he is going on a journey with Ivenes or when he gives her special illumination. This behaviour is certainly remarkable, for if Grandfather I is the hypnotist and completely separate from the personality of Ivenes, there seems no reason why he should not speak objectively at the same time that his double appears in the ecstasy. Although this might have been supposed possible, as a matter of fact it was never observed. How is this dilemma to be resolved? Sure enough there is an identity of I and II, but it does not lie in the realm of the personality under discussion; it lies rather in the basis common to both, namely in the personality of the patient, which is in the deepest sense one and indivisible.

[130] Here we come upon the characteristic feature of all hysterical splits of consciousness. They are disturbances that only touch the surface, and none of them goes so deep as to attack the firmly knit basis of the ego-complex. Somewhere, often in an extremely well-concealed place, we find the bridge which spans the apparently impassable abyss. For instance, one of four playing cards is made invisible to a hypnotized person by suggestion; consequently he calls only the other three. A pencil is then put into his hand and he is told to write down all the cards before him; he correctly adds the fourth one.[109] Again, a patient of Janet's[110] always saw, in the aura of his hysteroepileptic attacks, the vision of a conflagration. Whenever he saw an open fire he had an attack; indeed, the sight of a lighted match held before him was sufficient to induce one. The patient's visual field was limited to 30° on the left side; the right eye was closed. The left eye was then focused on the centre of a perimeter while a lighted match was held at 80°. An hysteroepileptic attack took place immediately. Despite extensive amnesia in many cases of double consciousness, the patients do not behave in a way that corresponds to the degree of their ignorance, but as though some obscure instinct still guided their actions in accordance with their former knowledge. Neither this relatively mild amnesic split nor even the severe amnesia of the epileptic twilight state, formerly regarded as an *irreparabile damnum*, is sufficient to sever the innermost threads that bind the ego-complex of the twilight

state to that of the normal state. In one case it was possible to articulate the content of the twilight state with the waking ego-complex.[111]

[131] If we apply these discoveries to our case, we arrive at the explanatory hypothesis that, under the influence of appropriate suggestions, the layers of the unconscious which are beyond reach of the split try to represent the unity of the automatic personality, but that this endeavour comes to grief on the profounder and more elementary disturbance caused by the hysterical attack.[112] This prevents a more complete synthesis by appending associations which are, as it were, the truest and most original property of the "supraconscious" personality. The dream of Ivenes, as it emerges into consciousness, is put into the mouths of the figures who happen to be in the field of vision, and henceforth it remains associated with these persons.

[*Origin of the Unconscious Personalities*]

[132] As we have seen, the various personalities are grouped round two types, the grandfather and Ulrich von Gerbenstein. The grandfather produces nothing but sanctimonious twaddle and edifying moral precepts. Ulrich von Gerbenstein is simply a silly schoolgirl, with nothing masculine about him except his name. We must here add, from the anamnesis, that the patient was confirmed at the age of fifteen by a very pietistic clergyman, and that even at home she had to listen to moral sermons. The grandfather represents this side of her past, Gerbenstein the other half; hence the curious contrast. So here we have, personified, the chief characters of the past: here the compulsorily educated bigot, there the boisterousness of a lively girl of fifteen who often goes too far.[113] The patient herself is a peculiar mixture of both; sometimes timid, shy, excessively reserved, at other times boisterous to the point of indecency. She is often painfully conscious of these contrasts. This gives us the key to the origin of the two subconscious personalities. The patient is obviously seeking a middle way between two extremes; she endeavours to repress them and strives for a more ideal state. These strivings lead to the adolescent dream of the ideal Ivenes, beside whom the unrefined aspects of her character fade into the background. They are not lost; but

as repressed thoughts, analogous to the idea of Ivenes, they begin to lead an independent existence as autonomous personalities.

[133] This behaviour calls to mind Freud’s dream investigations, which disclose the independent growth of repressed thoughts.[114] We can now understand why the hallucinatory persons are divorced from those who write and speak automatically. They teach Ivenes the secrets of the Beyond, they tell her all those fantastic stories about the extraordinariness of her personality, they create situations in which she can appear dramatically with the attributes of their power, wisdom, and virtue. They are nothing but dramatized split-offs from her dream-ego. The others, the automata, are the ones to be overcome; they must have no part in Ivenes. The only thing they have in common with her spirit companions is the name. It is not to be expected in a case like this, where no clear-cut divisions exist, that two such pregnant groups of characters, with all their idiosyncrasies, should disappear entirely from a somnambulistic ego-complex so closely connected with the waking consciousness. And in fact, we meet them again, partly in those ecstatic penitential scenes and partly in the romances that are crammed with more or less banal, mischievous gossip. On the whole, however, a very much milder form predominates.

Course of the Disorder

[134] It only remains now to say a few words about the course of this singular ailment. The whole process reached its climax within four to eight weeks, and the descriptions of Ivenes and the other subconscious personalities refer in general to this period. Thereafter a gradual decline became noticeable; the ecstasies grew more and more vacuous as Gerbenstein’s influence increased. The phenomena lost their plasticity and became ever shallower; characters which at first were well differentiated became by degrees inextricably mixed. The psychological yield grew more and more meagre, until finally the whole story assumed the appearance of a first-class fraud. Ivenes herself was severely hit by this decline; she became painfully uncertain, spoke cautiously, as if feeling her way, so that the character of the patient came through in more and more undisguised form. The somnambulistic attacks, too, decreased

in frequency and intensity. One could observe with one's own eyes all the gradations from somnambulism to conscious lying.

[135] Thus the curtain fell. The patient has since gone abroad. The fact that her character has become pleasanter and more stable may have a significance that is not to be underestimated, if we remember those cases where the second state gradually came to replace the first. We may be dealing here with a similar phenomenon.

[136] It is well known that somnambulistic symptoms are particularly common in puberty.[115] The attacks of somnambulism in Dyce's case[116] began immediately before the onset of puberty and lasted just till its end. The somnambulism of Hélène Smith is likewise closely connected with puberty.[117] Schroeder van der Kolk's patient was 16 at the time of her illness; Felida X., 14½. We know also that the future character is formed and fixed at this period. We saw in the cases of Felida X. and Mary Reynolds how the character of the second state gradually replaced that of the first. It is, therefore, conceivable that the phenomena of double consciousness are simply new character formations, or attempts of the future personality to break through, and that in consequence of special difficulties (unfavourable circumstances, psychopathic disposition of the nervous system, etc.) they get bound up with peculiar disturbances of consciousness. In view of the difficulties that oppose the future character, the somnambulisms sometimes have an eminently teleological significance, in that they give the individual, who would otherwise inevitably succumb, the means of victory. Here I am thinking especially of Joan of Arc, whose extraordinary courage reminds one of the feats performed by Mary Reynolds in her second state. This is also, perhaps, the place to point out the like significance of "teleological hallucinations," of which occasional cases come to the knowledge of the public, although they have not yet been subjected to scientific study.

Heightened Unconscious Performance

[137] We have now discussed all the essential phenomena presented by our case which were significant for its inner structure. Certain accompanying phenomena have still to be briefly considered; these are the phenomena of

heightened unconscious performance. In this field, we meet with a not altogether unjustifiable scepticism on the part of the scientific pundits. Even Dessoir’s conception of the second ego aroused considerable opposition and was rejected in many quarters as too enthusiastic. As we know, occultism has claimed a special right to this field and has drawn premature conclusions from dubious observations. We are still very far indeed from being able to say anything conclusive, for up to the present our material is nothing like adequate. If, therefore, we touch on this question of heightened unconscious performance, we do so only to do justice to all sides of our case.

[138] By heightened unconscious performance we mean that peculiar automatic process whose results are not available for the conscious psychic activity of the individual. Under this category comes, first of all, thought-reading by means of table movements. I do not know whether there are people who can guess an entire long train of thought by means of inductive inferences from the “intended tremors.” At any rate it is certain that, granting this to be possible, such persons must be making use of a routine acquired by endless practice. But in our case routine can be ruled out at once, and there is no choice but to assume for the present a receptivity of the unconscious far exceeding that of the conscious mind. This assumption is supported by numerous observations on somnambulists. Here I will mention only Binet’s experiments, where little letters or other small objects, or complicated little figures in relief, were laid on the anaesthesic skin of the back of the hand or the neck, and the unconscious perceptions were registered by means of signs. On the basis of these experiments he comes to the following conclusion: “According to the calculations that I have been able to make, the unconscious sensibility of an hysterical patient is at certain moments *fifty times* more acute than that of a normal person.”[118] Another example of heightened performance that applies to our case and to numerous other somnambulists is the process known as cryptomnesia.[119] By this is meant the coming into consciousness of a memory-image which is not recognized as such in the first instance, but only secondarily, if at all, by means of subsequent recollection or abstract reasoning. It is characteristic of cryptomnesia that the image which comes up does not bear the

distinctive marks of the memory-image—that is to say, it is not connected with the supraliminal ego-complex in question.

[139] There are three different ways in which the cryptomnesic image may be brought into consciousness:

(1) *The image enters consciousness without the mediation of the senses, intrapsychically*. It is a sudden idea or hunch, whose causal nexus is hidden from the person concerned. To this extent cryptomnesia is an everyday occurrence and is intimately bound up with normal psychic processes. But how often it misleads the scientist, author, or composer into believing that his ideas are original, and then along comes the critic and points out the source! Generally the individual formulation of the idea protects the author from the charge of plagiarism and proves his good faith, though there are cases where the reproduction occurs unconsciously, almost word for word. Should the passage contain a remarkable idea, then the suspicion of more or less conscious plagiarism is justified. After all, an important idea is linked by numerous associations to the ego-complex; it has been thought about at different times and in different situations and therefore has innumerable connecting threads leading in all directions. Consequently it can never disappear so entirely from consciousness that its continuity is lost to the sphere of conscious memory. We have, however, a criterion by which we can always recognize intrapsychic cryptomnesia objectively: the cryptomnesic idea is linked to the ego-complex by the minimum of associations. The reason for this lies in the relation of the individual to the object concerned, in the want of proportion between interest and object.

Two possibilities are conceivable: (*a*) The object is worthy of interest, but the interest is slight owing to distractibility or lack of understanding. (*b*) The object is not worthy of interest, consequently the interest is slight. In both cases there is an extremely labile connection with consciousness, the result being that the object is quickly forgotten. This flimsy bridge soon breaks down and the idea sinks into the unconscious, where it is no longer accessible to the conscious mind. Should it now re-enter consciousness by way of cryptomnesia, the feeling of strangeness, of its being an original creation, will cling to it, because the path by which it entered the subconscious can no longer be discovered. Strangeness and original creation are, moreover, closely allied to one another, if we remember the numerous witnesses in *belles-lettres* to the “possessed” nature of genius.[120] Apart from a number of striking instances of this kind, where it is doubtful whether it is cryptomnesia or an original creation, there are others where a passage of no essential value has been reproduced cryptomnesically, and in almost the same words, as in the following example:

[140]

Nietzsche, *Thus Spake Zarathustra*[121]	Kerner, *Blätter aus Prevorst*[122]
Now about the time that Zarathustra sojourned on the Happy Isles, it happened that a ship anchored at the isle on which the smoking mountain stands, and the crew went ashore to shoot rabbits. About the noontide hour, however, when the captain and his men were together again, they suddenly saw a man coming towards them through the air, and a voice said distinctly: “It is time! It is highest time!” But when the figure drew close to them, flying past quickly like a shadow in the direction of the volcano, they recognized with the greatest dismay that it was Zarathustra.… “Behold,” said the old helmsman, “Zarathustra goes down to hell!”	The four captains and a merchant, Mr. Bell, went ashore on the island of Mount Stromboli to shoot rabbits. At three o’clock they mustered the crew to go aboard, when, to their inexpressible astonishment, they saw two men flying rapidly towards them through the air. One was dressed in black, the other in grey. They came past them very closely, in the greatest haste, and to their utmost dismay descended amid the burning flames into the crater of the terrible volcano, Mount Stromboli. They recognized the pair as acquaintances from London.

[141] Nietzsche’s sister, Elisabeth Förster-Nietzsche, told me, in reply to my enquiry, that Nietzsche had taken a lively interest in Kerner when staying with his grandfather, Pastor Oehler, in Pobler, between the ages of 12 and 15, but certainly not later. It could scarcely have been Nietzsche’s intention to commit a plagiarism from a ship’s log; had this been the case he would surely have omitted that extremely prosaic and totally irrelevant

passage about shooting rabbits. Obviously, when painting the picture of Zarathustra's descent into hell, that forgotten impression from his youth must have slipped half or wholly unconsciously *into his* mind.

[142] This example shows all the peculiarities of cryptomnesia: a quite unimportant detail which only deserves to be forgotten as quickly as possible is suddenly reproduced with almost literal fidelity, while the main point of the story is, one cannot say modified, but re-created in an individual manner. Around the individual core—the idea of the journey to hell–there are deposited, as picturesque details, those old, forgotten impressions of a similar situation. The story itself is so absurd that the young Nietzsche, a voracious reader, probably skimmed through it without evincing any very profound interest in the matter. Here, then, is the required minimum of associative connections, for we can hardly conceive of a greater jump than from that stupid old tale to Nietzsche's consciousness in the year 1883. If we realize Nietzsche's state of mind[123] at the time when he wrote *Zarathustra*, and the poetic ecstasy that at more than one point verges on the pathological, this abnormal reminiscence will appear more understandable.

[143] The other of the two possibilities mentioned above, namely, registering some object, not in itself uninteresting, in a state of distractibility or partial interest due to lack of understanding, and its cryptomnesic reproduction, is found mainly in somnambulists, and also—as curiosities of literature—in people at the point of death.[124] Out of the rich choice of these phenomena we are chiefly concerned here with speaking in foreign tongues, the symptom of glossolalia. This phenomenon is mentioned in practically all cases of ecstasy; it is found in the New Testament, in the *Acta Sanctorum*,[125] in the witch trials, and in recent times in the story of the Clairvoyante of Prevorst, in Judge Edmond's daughter Laura, in Flournoy's Hélène Smith, who was thoroughly investigated on this question too, and also in Bresler's case,[126] which was probably identical with that of Blumhardt's Gottliebin Dittus.[127] As Flournoy has shown, glossolalia, in so far as it is a really independent language, is a cryptomnesic phenomenon par excellence. I

would refer the reader to Flournoy's exceedingly interesting study of this subject.[128]

[144] In our case glossolalia was observed only once, and then the only intelligible words were the interspersed variations of the word *vena*. The origin of this word is clear: a few days previously the patient had dipped into an anatomical atlas and immersed herself in a study of the veins of the face, which were given in Latin, and she used the word *vena* in her dreams, just as a normal person might do. The remaining words and sentences in foreign language reveal at a glance their derivation from the patient's slight knowledge of French. Unfortunately I did not get exact translations of the various sentences, because the patient refused to give them to me; but we can take it that it was the same sort of thing as Hélène Smith's Martian language. Flournoy shows that this Martian language was nothing but a childish translation from the French; only the words were altered, the syntax remained the same. A more probable explanation is that our patient simply strung a lot of meaningless foreign-sounding words together, and, instead of forming any true words,[129] borrowed certain characteristic sounds from French and Italian and combined them into a sort of language, just as Hélène Smith filled in the gaps between the real Sanskrit words with pseudo-linguistic products of her own. The curious names of the mystical system can mostly be traced back to known roots. Even the circles remind one of the planetary orbits found in every school atlas; the inner parallel with the relation of the planets to the sun is also pretty clear, so we shall not go far wrong if we see the names as reminiscences of popular astronomy. In this way the names "Persus," "Fenus," "Nenus," "Sirum," "Surus," "Fixus," and "Pix" can be explained as childish distortions of "Perseus," "Venus," "Sirius," and "fixed star," analogous to the *vena* variations. "Magnesor" is reminiscent of "magnetism," whose mystical significance the patient knew from the Clairvoyante of Prevorst story. "Connesor" being contrary to "Magnesor," the first syllable "Con-" suggests French "contre." "Hypos" and "Hyfonism" remind one of "hypnosis" and "hypnotism," about which the weirdest ideas still circulate amongst laymen. The frequent endings in "-us" and "-os" are the signs by which most people distinguish between Latin and Greek. The other names derive from similar accidents to which

we lack the clues. Naturally the modest glossolalia of our case cannot claim to be a classic example of cryptomnesia, for it consists only in the unconscious use of different impressions, some optical, some acoustic, and all very obvious.

[145] (2) *The cryptomnesic image enters consciousness through mediation of the senses, as an hallucination*. Hélène Smith is the classic example of this. See the case cited above, concerning the number 18 [par. 98].

[146] (3) *The image enters consciousness by motor automatism*. Hélène Smith had lost a very valuable brooch which she was anxiously looking for everywhere. Ten days later her guide Leopold told her by table movements where it was. From the information received, she found it one night in an open field, covered by sand.[130] Strictly speaking, in cryptomnesia there is no heightened performance in the true sense of the term, since the conscious memory experiences no intensification of function but only an enrichment of content. Through the automatism certain areas which were previously closed to consciousness are made accessible to it in an indirect way, but the unconscious itself is not performing any function that exceeds the capacities of the conscious mind either qualitatively or quantitatively. Cryptomnesia is therefore only an apparent instance of heightened performance, in contrast to hypermnesia, where there is an actual increase of function.[131]

[147] We spoke earlier of the unconscious having a receptivity superior to that of the conscious mind, chiefly in regard to simple thought-transference experiments with numbers. As already mentioned, not only our somnambulist but a fairly large number of normal people are able to guess, from tremor movements, quite long trains of thought, provided they are not too complicated. These experiments are, so to speak, the prototype of those rarer and incomparably more astonishing cases of intuitive knowledge displayed at times by somnambulists.[182] Zschokke has shown from his own self-analysis[133] that such phenomena occur in connection not only with somnambulism but with non-somnambulists as well.

[148] This knowledge seems to be formed in several different ways. The first thing to be considered, as we have said, is the delicacy of

unconscious perceptions; secondly, we must emphasize the importance of what proves to be the enormous suggestibility of somnambulists. The somnambulist not only incorporates every suggestive idea into himself, he actually lives himself into the suggestion, into the person of the doctor or observer, with the utter abandon characteristic of suggestible hysterics. Frau Hauffe's relation to Kerner is an excellent example of this. So it not surprising that there is in these cases a high degree of concord of associations, a fact which Richet, for instance, might have taken more account of in his experiments on thought-transference. Finally, there are cases of somnambulistic heightened performance which cannot be explained solely by the hyperaesthetic unconscious activity of the senses, or by the concord of associations, but which postulate a highly developed intellectual activity of the unconscious. To decipher the intended tremor movements requires an extraordinary delicacy of feeling, both sensitive and sensory, in order to combine the individual perceptions into a self-contained unit of thought—if indeed it is permissible at all to make an analogy between the cognitive processes in the unconscious and those of the conscious. The possibility must always be borne in mind that, in the unconscious, feelings and concepts are not so clearly separated, and may even be one. The intellectual exaltation which many somnambulists display during ecstasy, though rather uncommon, is a well-observed fact,[134] and I am inclined to regard the mystical system devised by our patient as just such an example of heightened unconscious performance that transcends her normal intelligence. We have already seen where part of that system probably comes from. Another source may be Frau Hauffe's "life-circles," depicted in Kerner's book. At any rate its outward form seems to be determined by these factors. As we have already noted, the idea of dualism derives from those fragments of conversation overheard by the patient in the dreamy state following her ecstasies.

[4. CONCLUSION]

[149] This exhausts my knowledge of the sources used by the patient. Where the root idea came from she was unable to say. Naturally I waded through the occult literature so far as it pertained to this subject, and

discovered a wealth of parallels with our gnostic system, dating from different centuries, but scattered about in all kinds of works, most of them quite inaccessible to the patient. Moreover, at her tender age, and in her surroundings, the possibility of any such study must be ruled out of account. A brief survey of the system in the light of the patient’s own explanations will show how much intelligence was expended on its construction. How high the intellectual achievement is to be rated must remain a matter of taste. At all events, considering the youth and mentality of the patient, it must be regarded as something quite out of the ordinary.

[150] In conclusion, I would like to express my warmest thanks to my revered teacher, Professor Bleuler, for his friendly encouragement and the loan of books, and to my friend Dr. Ludwig von Muralt for his kindness in handing over to me the first case mentioned in this book (case of Miss E.).[135]

ON HYSTERICAL MISREADING[1]

[151] In his review of my paper "On the Psychology and Pathology of So-called Occult Phenomena,"[2] Mr. Hahn misrepresented my views on "hysterical misreading." Since I regard this phenomenon as being of fundamental importance, perhaps I may be allowed to state my views once again.

[152] My patient misread with remarkable frequency at school, and always in a quite definite way: each time she substituted the Swiss dialect word for the word in question, so instead of saying "Treppe" (stair) she said "Stege," and instead of "Ziege" (goat) she said "Geiss," and so on.[3] These expressions are absolutely synonymous. Hence, if the word "Stege" is produced, it proves that the meaning of the word "Treppe" was understood. There are two possible ways of explaining this phenomenon:

[153] (1) The word "Treppe" is understood correctly and consciously. In this case there is absolutely no reason for a healthy person to reproduce the word incorrectly, i.e., as a dialect word. But with my patient the dialect word somehow crept in.

[154] (2) The word "Treppe" is not understood correctly. In this case any normal person will reproduce nonsense that either sounds like or looks like the word, but he will never reproduce an expression that sounds and looks different but is synonymous. I have made numerous reading-tests with patients suffering from paralysis, mania, alcoholism, senile dementia, etc., who are distractible and unable to concentrate, and on the basis of hundreds of these experiences I can confidently assert that this kind of misreading does not occur in individuals who are not hysterical. Every misreading that occurs in a state of distractibility is based on a phonetic or a textual likeness; with normal persons it is usually caused by momentary constellations. I have found this rule amply confirmed by association tests conducted under conditions of distraction.

[155] If, therefore, my patient reproduces dialect words instead of the literary ones without noticing this frequently repeated mistake, she has in the first place a defective acoustic control of what she is saying; and, in the second place, the synonym shows that the meaning of the optic impression was understood correctly. But it is reproduced incorrectly. Where does the cause of the mistake lie? In my paper I left this question open, contenting myself with the general remark that it was an "automatic" phenomenon which I was not able to localize at the time.

[156] The most probable explanation is as follows: We know from everyday experience that the ordinary kind of misreading disturbs the sense by substituting for the right word a word akin to it in sound or form. Slips of the tongue in uttering a correctly understood word follow the same rule, and when, as often happens, a Swiss finds himself uttering a dialect word, he very rarely does so when reading out loud, and the words that are confused with one another are mostly those with a strong phonetic affinity. This cannot be said of the example I have deliberately chosen: "Ziege—Geiss." In order to explain their confusion, we have to assume an additional factor. This additional factor is the patient's hysterical disposition.

[157] Our dreamy, somewhat drowsy patient reads mechanically; her comprehension of the meaning is therefore practically nil. While her conscious mind is occupied with something quite different, the psychic processes set in motion by her reading remain feeble and indistinct. In normal and sick persons who are distractible but not hysterical, these feebly accentuated psychic processes give rise to misconstructions based on a phonetic or formal likeness, so that reproduction is falsified at the cost of sense. It is the other way round with my patient: the formal connection breaks down completely but the sense connection is preserved. This can only be explained on the hypothesis of a split consciousness; that is to say, besides the ego-complex, which follows its own thoughts, there is another conscious complex which reads and understands correctly, and allows itself various modifications of expression, as indeed is frequently the case with complexes that function automatically. Hysterical misreading differs from all other types in that, despite the misreading, the sense is preserved during reproduction.

[158] If Mr. Hahn fails to understand this well-known automatization of psychic functions in the psychopathology of hysteria, I can only recommend him to a study of the literature and to a little practical observation on his own account. Literature and reality abound in analogous phenomena.

[159] The reason why I attach particular importance to hysterical misreading is that it demonstrates in a nutshell the splitting off of psychic functions from the ego-complex, which is such a characteristic of hysteria, and consequently the strong tendency of the psychic elements towards autonomy.

[160] In my paper, I cited by way of analogy the observations made by Binet,[4] who, having anaesthetized the subject's hand by hypnosis (split it off from the ego-complex), pricked it with a needle under the cover of a screen, whereupon the subject suddenly thought of a row of dots (corresponding to the number of pricks). Or Binet would move the subject's fingers, and she at once thought of "sticks" or "columns"; or the anaesthetic hand was induced to write the name "Salpêtrière," and the subject suddenly saw "Salpêtrière" before her, in white writing on a black ground.

[161] Mr. Hahn is of the opinion that these observations have to do with "something essentially different" from misreading. What is this something? Mr. Hahn does not say.

[162] Binet's experiments make it clear that the conscious complex which is split off from the ego-complex, and upon which the anaesthesia of the arm depends, perceives things correctly but reproduces them in modified form.

[163] The ego-complex of my patient is displaced from the act of reading by other ideas, but the act continues automatically and forms a little conscious complex on its own, which likewise understands correctly but reproduces in modified form.

[164] The type of process is therefore the same, for which reason my reference to Binet's experiments is fully justified. It is a type that repeats itself over the whole field of hysteria; for instance, the systematic

"irrelevant answers" of hysterical subjects, which have only recently been publicized, would also come into this category.

[165] For the rest, I would like to point out that the main emphasis of my paper falls on the fullest possible registration and analysis of the manifold psychological phenomena which are all intimately connected with the development of character at this time of life. The analysis of the clinical picture is not, as Mr. Hahn thinks, based on French writers, but on Freud's investigations of hysteria. Mr. Hahn would like to see the analysis "carried further and pursued more rigorously." I would be very much obliged to Mr. Hahn if, together with his criticism, he would specify new ways of investigating this very difficult field.

II

CRYPTOMNESIA

CRYPTOMNESIA[1]

[166] Modern scientific psychology distinguishes between direct and indirect memory. You have a direct memory when, for instance, you see a certain house and it then "comes into your mind" that a friend of yours lived there some years ago. You see the well-known house, and by the law of association the coexistent memory-image of your friend enters your consciousness. An indirect memory is different: I walk, deep in thought, past the house where my friend X used to live. I pay no attention either to the house or to the street, but am thinking of some urgent business matter I have to attend to. Suddenly an unexpected image thrusts itself obtrusively between my thoughts: I see a scene in which X once discussed similar matters with me many years ago. I am surprised that this particular memory should come up, for the conversation was of no importance. Suddenly I realize that I am in the street where my friend once lived. In this case the association of the memory-image with the house is indirect: I did not perceive the house consciously, for my thoughts distracted me from my surroundings too much. But the perception of the house nevertheless slipped into the dark background of consciousness[2] and activated the association with X. As this association was too feebly accentuated to cross the threshold of consciousness, a common association had to intervene as an auxiliary. This mediating association is the memory-image of the conversation that touched on matters similar to those now being revolved in my consciousness. In this way, the memory-image of X enters the sphere of consciousness.

[167] The direct and the indirect memory-image have one quality in common: the quality of being known. I recognize the association as an image I remember, and therefore know that it is not a new formation. The images we combine anew lack this quality of being known. I say "combine," because originality lies only in the combination of psychic elements and not in the material, as everything in nature eloquently

testifies. If a new combination has the quality of being known it is something abnormal: a deception of memory. The million acts of recollection daily taking place in our brain consist for the most part of direct memories, but a considerable number of them will fall on the side of indirect memory. These last are especially interesting. As our example of indirect memory shows, an unconscious perception that enters the brain passively can spontaneously activate a related association and in this way reach consciousness. The unconscious perception therefore does what our consciousness ordinarily does when we look at the house and ask ourselves "Who lived there?" in order to evoke a clear memory. We thus call back the image of X into our minds. The unconscious perception behaves in exactly the same way; it seeks out the memory-image related to it, and in our example (by a psychological law which I do not propose to go into here) it combines with something that is being gently activated from the other side, namely the image of X talking of similar business matters. We see from this that association can take place without the least assistance from consciousness.

[168] From the way it entered my consciousness as an indirect memory, the image of X would commonly be described as a "chance idea," and the German word *Einfall* clearly expresses the apparently fortuitous and groundless nature of the phenomenon. This kind of indirect memory is very common among people who think intuitively rather than in logical sequence–so common that we often forget how strictly determined all psychic processes are. To take a simple example: I am working away at some casual task, whistling a tune, some popular song whose words I don't even remember at the moment. Somebody asks me what tune it is. I cast round in my memory: it is the student song "Not a cent, not a cent, and my clothes are only lent!" I have no idea how I came to pick on this particular song, which has nothing whatever to do with the associations now engaging my conscious mind. I go back along the train of thought I followed while working. All at once I remember that a few minutes ago I had been thinking, with a certain amount of feeling-tone, of a grand settlement of accounts in the New Year. Hence the song! I need hardly add that one can carry out some very pretty psychological diagnoses on one's fellows in this way. For instance, when a friend of mine was

imprudent enough to whistle three little melodies within a space of ten minutes, I could tell him to his face how sorry I was to hear that his love affair had ended unhappily. The melodies were “Im Aargau sind zwei Liebei” (“In Aargau are two lovers,”—a Swiss folksong), “Verlassen, verlassen bin i” (“Forlorn, forlorn am I”), and “Steh ich in finstrer Mitternacht” (“I stand in midnight’s gloom”). It even happened that on one occasion I whistled a tune whose text I did not know. On making inquiries I discovered a text that was undoubtedly associated with a strongly feeling-toned[2a] train of thought I had pursued five minutes before.

[169] These examples, which one can observe every day in oneself and others, clearly show that a (feeling-toned) train of thought can disappear from the conscious mind without therefore ceasing to exist. On the contrary, it still has sufficient energy to send up, in the midst of the conscious world of associations that have completely changed in the meantime, an idea that bears no relation to its momentary surroundings.

[170] Still more drastic examples are provided by hysteria, which is nothing other than a caricature of normal psychological mechanisms. Recently I had to treat a hysterical young lady who became ill chiefly because she had been brutally beaten by her father. Once, when we were out for a walk, this lady dropped her cloak in the dust. I picked it up, and tried to get the dust off by beating it with my stick. The next moment the lady hurled herself upon me with violent defensive gestures and tore the cloak out of my hands. She said she couldn’t stand the sight, it was quite unendurable to her. I at once guessed the connection and urged her to tell me the motives for her behaviour. She was nonplussed, and could only say that it was extremely unpleasant for her to see her cloak cleaned like that. These symptomatic actions, as Sigmund Freud calls them, are very common among hysterics. The explanation is simple. A feeling-toned memory complex, though not present in consciousness at the moment, motivates certain actions from its invisible seat in the unconscious just as if it were present in the conscious mind.

[171] We can confidently say that our consciousness fairly swarms with strange intruders of this kind, which would be hard put to it to establish

their identity. Every day thousands of associations enter the luminous circle of consciousness, and we would question them in vain for a more specific account of their origins. We must always bear in mind that conscious psychic phenomena are only a very small part of our total psyche. By far the greater part of the psychic elements in us is unconscious.

[172] Our consciousness therefore finds itself in a rather precarious position with regard to automatic movements of the unconscious that are independent of our will. The unconscious can perceive, and can associate autonomously; and the trouble is that only those associations which have once passed through our conscious minds have the quality of being known, and many of them can fall into oblivion so completely that they lose any such quality. Our unconscious must therefore harbour an immense number of psychic complexes which would astonish us by their strangeness. The inhibitions imposed by our waking consciousness do something to protect us from invasions of this kind. But in dreams, when the inhibitions of the conscious mind are lifted, the unconscious can play the maddest games. Anyone who has read Freud’s dream analyses or, better still, has done some himself, will know how the unconscious can bedevil the most innocent and decent-minded people with sexual symbols whose lewdness is positively horrifying. It is to this unconscious that all those who do creative work must turn. All new ideas and combinations of ideas are premeditated by the unconscious. And when our own consciousness approaches the unconscious with a wish, it was the unconscious that gave it this wish. The unconscious brings the wish and its fulfilment.

[173] On this treacherous ground wander all who seek new combinations of ideas. Woe to them if they do not continually exercise the most rigorous self-criticism!

[174] Since, in the airy world of thought, one usually finds what one seeks, and gets what one wishes, the man who seeks new ideas will also be the most easily enchanted with the deceptive gifts of the psyche. Not only is the history of religion or the psychology of the masses rich in examples, but so is the intellectual life of anyone who has ever hoped to achieve

anything. What poet or composer has not been so beguiled by certain of his ideas as to believe in their novelty? We believe what we wish to believe. Even the greatest and most original genius is not free from human wishes and their all-too-human consequences.

[175] Quite apart from this general proposition, what kind of people seek these new combinations? They are the men of thought, who have finely-differentiated brains coupled with the sensitivity of a woman and the emotionality of a child. They are the slenderest, most delicate branches on the great tree of humanity: they bear the flower and the fruit. Many become brittle *too soon*, many break off. Differentiation creates in its progress the fit as well as the unfit; wits are mingled with nitwits—there are fools with genius and geniuses with follies, as Lombroso has remarked. One of the commonest and most usual marks of degeneracy is hysteria, the lack of self-control and self-criticism. Without succumbing to the pseudo-psychiatric witch-hunting of an author like Nordau,[3] who sees fools everywhere, we can assert with confidence that unless the hysterical mentality is present to a greater or lesser degree genius is not possible. As Schopenhauer rightly says, the characteristic of the genius is great sensibility, something of the mimosa-like quality of the hysteric. Geniuses also have other qualities in common with hysterical persons.

[176] It may be that the majority of hysterical persons are ill because they possess a mass of memories, highly charged with affect and therefore deeply rooted in the unconscious, which cannot be controlled and which tyrannize the conscious mind and will of the patient. With women it is sometimes disappointed hopes of love, sometimes an unhappy marriage; with men, a bad position in life or unrewarded merits. They try to repress the affect from their daily lives, and so it torments them with horrid dream-symbols at night, plagues them with fits of precordial anxiety by day, saps their energy, drives them into all kinds of crazy sects, and causes headaches that defy all the medicine-men and all the magic remedies of electricity, sun-baths, and food cures. The genius, too, has to bear the brunt of an outsize psychic complex; if he can cope with it, he does so with joy, if he can’t, he must painfully perform the “symptomatic actions” which his gift lays upon him: he writes, paints, or composes what he suffers.

[177] This applies more or less to all productive individuals. Tapping the depths of the psyche, the instinctively functioning complex sends up from its unknown and inexhaustible treasury countless thoughts to its slave "consciousness," some old and some new, and consciousness must deal with them as best it can. It must ask each thought: Do I know you, or are you new? But when the daemon drives, consciousness has no time to finish its sorting work, the flood pours into the pen—and the next day is perhaps already printed.

[178] I said earlier that only the combinations are new, not the material, which hardly alters at all, or only very slowly and almost imperceptibly. Have we not seen all Böcklin's hues already in the old masters? And were not the fingers, arms, legs, noses and throats of Michelangelo's statues all somehow prefigured in antiquity? The smallest parts of a master work are certainly always old, even the next largest, the combined units, are mostly taken over from somewhere else; and in the last resort a master will not scorn to incorporate whole chunks of the past in a new work. Our psyche is not so fabulously rich that it can build from scratch each time. Neither does nature. One can see from our prisons, hospitals, and lunatic asylums at what enormous cost nature takes a little step forward; she builds laboriously on what has gone before.

[179] This process in the world at large is repeated in the smaller world of language: few novel combinations, nearly all of it old fragments taken over from somewhere. We speak the words and sentences learnt from parents, teachers, books; anyone who talks fastidiously, whether because he has a gift for language or because he takes pleasure in it, talks "like a book"—the book he has just been reading; he repeats rather larger fragments than do other people. The ordinary decent person either does not talk that way or openly admits where he got it from. But if somebody reproduces a sentence eight lines long verbatim from somebody else, we cannot, it is true, peremptorily shut the mouths of those who cry "Plagiarism!"—for as a matter of fact plagiarisms do occur—but neither need we immediately drop the person to whom this misfortune happens. For, when nature instituted the faculty of remembrance, she did not tie herself exclusively to the possibility of direct and indirect memories; she also gave, to clever and foolish alike, the power of cryptomnesia.

[180] The word “cryptomnesia” is a technical term taken from French scientific literature. The Swiss psychologist Flournoy has made particularly valuable contributions, based on case material, to our knowledge of this phenomenon.[4] Cryptomnesia means something like “hidden memory.” What this means in practice is best shown by a concrete example.[5] When, some years ago, I read about Zarathustra’s journey to hell, I was particularly struck by the passage where Nietzsche describes how Zarathustra descends into hell through the mouth of a volcano. It seemed to me that I had read this description somewhere before. I thought at first that it must be a falsification of memory on my part (abnormal quality of being known), but finally the most startling aspect of this quality settled on the passage where the crew of the ship went ashore “to shoot rabbits.” This passage preoccupied my thoughts for several days, till at last I remembered having read a similar story some years earlier in Justinus Kerner. I leafed through his *Blätter aus Prevorst*, that antiquated collection of simple-minded Swabian ghost stories, and found the following tale, which I put side by side with the corresponding passage from Nietzsche:

[181]

Nietzsche, *Thus Spake Zarathustra*[6]	Kerner, *Blätter aus Prevorst*[7]
Now about the time that Zarathustra sojourned on the Happy Isles, it happened that a ship anchored at the isle on which the smoking mountain stands, and the crew went ashore to shoot rabbits. About the noontide hour, however, when the captain and his men were together again, they suddenly saw a man coming towards them through the air, and a voice said distinctly: “It is time! It is highest time!” But when the figure drew close to them, flying past quickly like a shadow in the direction of the volcano, they	The four captains and a merchant, Mr. Bell, went ashore on the island of Mount Stromboli to shoot rabbits. At three o’clock they mustered the crew to go aboard, when, to their inexpressible astonishment, they saw two men flying rapidly towards them through the air. One was dressed in black, the other in grey. They came past them very closely, in the utmost haste, and to their greatest dismay descended amid the burning flames into the crater of the terrible volcano, Mount Stromboli. They

recognized with the greatest dismay that it was Zarathustra.… “Behold,” said the old helmsman, “Zarathustra goes down to hell!”	recognized the pair as acquaintances from London.
[Nietzsche introduces this story with the words: “They say … that through the volcano itself the narrow path leads down to the gate of the underworld.”]	[Kerner goes on to say that when the travellers returned to London, they learnt that two acquaintances had died in the meantime, the very ones whom they saw on Stromboli. From this story it was concluded that Stromboli was the entrance to hell.]

[182] One can see at once that the similarity between the two stories cannot be mere chance. The main argument in its disfavour is the number of verbal correspondences and the reproduction of unimportant details like “to shoot rabbits.” A plagiarism, therefore! Everyone will find this supposition absurd. Why? Because the passage is too unimportant in relation to Nietzsche’s artistic intention. And not only unimportant, but largely superfluous and unnecessary. The rabbits, for instance, characterize nothing in particular, whether we imagine the “Happy Isles” as the Lipari Islands or the Canary Islands. Nor is the description made any more felicitous by the rabbits—on the contrary. The thing is not easy to explain psychologically. The first question is, when did Nietzsche read the *Blätter aus Prevorst?* As I learnt from a letter which Frau Förster-Nietzsche wrote me, Nietzsche took a lively interest in Justinus Kerner when staying with his grandfather, Pastor Oehler, in Pobler, between the ages of 12 and 15, but probably not later. As Nietzsche had to be very economical in his reading because of his weak eyes, it is difficult to understand what could have lured him back to this childish wonder-book in his later years, and the explanation of the plagiarism then becomes even more difficult. I think we may take it that Nietzsche read this story in his early youth and never again afterwards. How then did he come to reproduce this passage?

[183] I believe, though I cannot prove it, that it was not this old wives’ tale that gave Nietzsche the idea of Zarathustra’s journey to hell. Rather, while he was working out the general idea, Kerner’s story would have slipped into his mind because it was associated with the general idea “journey to hell” by the law of similarity. The remarkable thing is the verbal fidelity of the reproduction. The striking agreement between the two texts strongly suggests that the reproduction did not come from the sphere of conscious memory, otherwise Nietzsche would have to be credited with a memory that was absolutely amazing. The normal powers of memory offer no explanation; it is almost inconceivable that Nietzsche could have reawakened that old sequence of words by a voluntary act of evocation. The reappearance of old, long-forgotten impressions is, however, explicable in terms of the physiology of the brain. The brain never forgets any impression, no matter how slight; every impression leaves behind it some trace in the memory, no matter how fine. Consciousness, on the other hand, operates with an unending loss of previous impressions, much as the Bank of England always destroys after a certain lapse of time the notes that are daily returned to it. Under special conditions the re-emergence of old memory traces with photographic fidelity is by no means impossible. Literature records not a few cases of dying people, or people in other abnormal mental states, who recited whole chains of earlier impressions which perhaps never belonged to the sphere of conscious memory at all. Eckermann[8] mentions an old man “of low station” who, on his deathbed, suddenly began talking Greek. It turned out that a number of Greek verses had been drummed into him as a child, so that he should serve as a shining example to a lazy pupil of noble birth. I know another case where an old maidservant recited from the Bible passages in Greek and Hebrew on her deathbed. Investigations showed that as a young girl she had worked for a priest who had the habit of walking up and down after meals, reading the Bible aloud in the original tongues. The Viennese psychiatrist, Krafft-Ebing, who died recently, reports the case of a sixteen-year-old hysterical girl who, in an ecstatic state, could repeat without difficulty a poem, two pages long, which she had read shortly before.

[184] As these examples show, the physiology of the brain makes such reproductions possible. But, for them to take place, an abnormal mental state is always needed, which can justifiably be conjectured in Nietzsche's case at the time when he wrote *Zarathustra*. One has only to think of the incredible speed with which this work was produced.

> There is an ecstasy so great that the tremendous strain of it is at times eased by a storm of tears, when your steps now involuntarily rush ahead, now lag behind; a feeling of being completely beside yourself, with the most distinct consciousness of innumerable delicate thrills tingling through you to your very toes; a depth of happiness, in which pain and gloom do not act as its antitheses, but as its condition, as a challenge, as necessary shades of colour in such an excess of light.[9]

So he himself describes his mood. These shattering extremes of feeling, far transcending his personal consciousness, were the forces that called up in him the remotest and most hidden associations. Here, as I said before, consciousness only plays the role of slave to the daemon of the unconscious, which tyrannizes over it and inundates it with alien ideas. No one has described the state of consciousness when under the influence of an automatic complex better than Nietzsche himself:

> Has any one at the end of the nineteenth century any distinct notion of what poets of a stronger age understood by the word "inspiration"? If not, I will describe it. If one had the smallest vestige of superstition left in one, it would hardly be possible to set aside the idea that one is the mere incarnation, mouthpiece, or medium of an almighty power. The idea of revelation, in the sense that something which profoundly convulses and shatters one becomes suddenly visible and audible with indescribable certainty and accuracy, describes the simple fact. One hears—one does not seek; one takes-one does not ask who gives; a thought suddenly flashes up like lightning, it comes with necessity, without faltering—I never had any choice in the matter.[10]

There could scarcely be a better description of the impotence of consciousness in face of the tremendous automatism driving up from the unconscious. Only this elemental force can wrench from oblivion the oldest and most delicate traces in a man's memory, while yet he retains his full senses. When the brain dies, and consciousness disintegrates, while the cerebral cortex still goes on drowsily working for a bit, automatically and without co-ordination, fragmentary memories may be reproduced together with a mass of morbid rubbish. The same thing happens in insanity. I recently observed a case of compulsive talking in a feeble-minded girl. She rattled away for hours on end about all the warders she had ever met in her life, including their families, their children, the arrangement of the rooms, describing everything down to the craziest detail—a marvellous performance that could not possibly have been a voluntary evocation. The work of genius is very different; it fetches up these distant fragments in order to build them into a new and meaningful structure.

[185] These psychic processes, where an automatic creative force causes lost memories to reappear in sizeable fragments and with photographic fidelity, are what science calls cryptomnesia.

[186] The case of Jacobsohn, which I know only from the remarks of Harden and Schnitzler,[11] would seem to have much in common with cryptomnesia; at any rate I could not say why it should not be so. From this one might, perhaps, draw conclusions about the strength of Jacobsohn’s talent and his passion for art, but hardly, as Schnitzler ventures to do, about his state of mind, let alone infer a focal lesion of the speech centres. Symptoms of a lesion in Broca’s convolution and the neighbouring areas of the brain bear little resemblance to cryptomnesia. I am on the contrary inclined to give Jacobsohn a good prognosis, for the time being, as regards his artistic production. Should any human ill befall him, it would be the purest accident if the cortex of his speech convolutions were also affected.

III

ON MANIC MOOD DISORDER

ON MANIC MOOD DISORDER[1]

[187] Under the term “manic mood disorder” I would like to publish a number of cases whose peculiarity consists in chronic hypomanic behaviour. A constitutional mood disorder characterized by melancholy and irritability has been known for some time, but only recently has attention been drawn to cases which, while still coming into the category of psychopathic inferiority, are remarkable for their excessively “sanguine temperament.” So far as I know from the relevant literature, Siefert[2] was the first to publish a case of this kind. It offered clear indications of a manic state, which, as the anamnesis showed, was chronic and could be followed back into youth. The patient was 36 years old on his admission, and had suffered a severe head trauma at the age of nine. He was intelligent and a skilled worker. Later, however, he led a vagabond’s life, was a deserter, thief, jail-breaker, and hardened alcoholic. He was arrogant in his behaviour, tremendously active, full of noble intentions and plans for world betterment, showing flight of ideas and surprisingly little need for sleep.

[188] In earlier writers we find only the barest hints, which might possibly refer to similar cases, as for instance in Pinel,[3] whose *manie sans délire* with unimpaired brain activity and maniac behaviour is nevertheless too wide a frame for the narrowly circumscribed clinical picture we have in mind. The *mania chronica* mentioned in Mendel[4] is a “secondary psychopathic state” with imbecility; a picture that hardly fits here. Even in Koch, Schüle, Krafft-Ebing, and others we find no mention of these states. In 1896, van Deventer[5] published a second case under the term “sanguine inferiority,” which comes midway between the “sanguine-tempered normal person on the one hand and the maniac on the other.” The patient had an hereditary taint, was excitable and wayward from youth up, of good intelligence, skilled in various crafts, always cheerful and carefree, but with a wild and turbulent character, morally defective in

every sense, showing flight of ideas, dangerous recklessness, and immense activity, occasionally also deep depressions.

[189] In his *Grundriss der Psychiatrie*,[6] Wernicke gives an excellent description of these cases under the term “chronic mania.” He can say “nothing certain” about their causation, but thinks it safe to say that a pure mania never terminates in such a chronic state. The case he cites was preceded by a psychosis of several years’ standing, about which no information was available. He describes this state as follows:

> Chronic mania has all the essential marks of acute mania, only these are modified in accordance with the conditions of a chronic, stable state. Hence, the flight of ideas keeps within the bounds of moderation, and can still be influenced to some extent by reflection and self-control. The elated mood is less marked, but occasionally it breaks through. On the other hand, the irascible mood is maintained owing to unavoidable conflicts with society. The heightened feeling of self-confidence, though not amounting to real megalomania, is very marked and gives these persons a certainty of address which, combined with their undeniable mental productivity, helps them to get on in the world. At the same time, they create for themselves all sorts of difficulties and conflicts by disregarding all the norms and checks which are imposed on them by custom and law. They have no consideration for others, yet demand every consideration for themselves. No signs of any formal disturbance of thinking need be present in this state.

[190] Although this general description fits in very well with the picture of a chronic hypomanic state, it still seems to me rather too broad, since it could also cover a large number of instabilities listed by Magnan—many querulous and morally feebleminded persons (moral insanity). As experience shows, in many psychopathic illnesses there are persons who think unclearly and are prone to flights of ideas, who are ruthlessly egocentric, irascible, and mentally productive, but who can hardly be said to be suffering from chronic mania. In order to arrive at an accurate diagnosis, we require the symptoms of mania in more definite form. Occasional elation, exaggerated self-confidence, mental productivity, conflicts with law and order are not in themselves sufficient to warrant a

diagnosis of “chronic mania.” For this we need the cardinal symptoms: emotional lability with predominantly elated mood, flight of ideas, distractibility, over-activity, restlessness, and–dependent on these symptoms-exaggerated self-importance, megalomaniac ideas, alcoholism, and other moral defects.

[191] So far as the term “manic mood disorder” is concerned, I would prefer van Deventer’s “sanguine inferiority,” because in my view it gives a more accurate description of what the term connotes. We have long been familiar with the idea of a constitutional melancholic mood, connoting a picture whose position midway between “healthy” and “diseased” exactly corresponds to that of the constitutional manic mood. As to the term “chronic mania” in the sense used by Siefert and Wernicke, this expression seems to me altogether too strong, for it is not a question of a real mania at all but of a hypomanic state which yet cannot be regarded as psychotic. The relatively mild manic symptoms are not partial manifestations of a periodic mania and are therefore seldom found in isolation; rather, they are frequently mixed with other psychopathic features, and this is only what one would expect, since the borderlines between the various clinical pictures of psychopathic inferiority are extraordinarily indistinct and fluctuating. Over-accentuation of the ego, periodicity of various symptoms, such as irritability, depression, exacerbation of stable abnormalities, hysterical traits, etc., are found in nearly all cases of degeneracy, without there necessarily being any deeper connection with the basic symptoms. This is all the more reason for delimiting the picture as closely as possible, and the first requisite is always the presence of the fundamental manic symptoms.

1

[192] The following case presents a very mild form of manic mood disorder bordering on simple psychopathic instability.

[193] CASE A, born 1875, business man. Heredity: father contracted paralysis of the insane twelve years after the birth of the patient. Other members of the family healthy. Patient was a bright, clever child,

physically rather weak. Scarlet fever at 8 years old. States that at school he was absent-minded and inattentive, always up to tricks. Severe attack of diphtheria in his twelfth year, with subsequent paralysis of accommodation and of the palate. Was afterwards lazy and superficial in his school-work, but showed great capabilities if he took the trouble. Easily moved to tears, became much more “difficult to understand” after the diphtheria. Entered high school at 13, found the work very easy, was always at the top of his class, extremely gifted but lacked perseverance. Early tendency to abuse of alcohol, no intolerance. Always in a cheerful mood, without worries. Matriculated with distinction. Afterwards he entered the business firm of a relative. Found it didn’t suit him, did little work, let himself be distracted by pleasures of all kinds. A year later, he volunteered for one year’s military service in the cavalry. Heavy abuse of alcohol at first only in merry company, then always before military duty, in order to calm his tremor; always had a full bottle by him, “knocked it back like anything.” Was the master of ceremonies and life and soul of the party. In the last months of military service, apparently only four hours sleep per night without fatigue next day. Then another year at home. Did practically no work. In recent months he gradually got fits of moodiness which lasted a day and repeated themselves at irregular intervals every two months. At these times he was in an abysmal bad humour, sometimes irritable, sometimes depressed, had gloomy thoughts, took a pessimistic view of the world, was often so irritable that when his mother or sister asked him anything he had to keep a grip on himself so as not to “bang both fists on the table.” He couldn’t settle down to any work, a “terrible inner restlessness” plagued him continually, an “everlasting restless urge to get away,” to change his situation, kept him from any profitable activity. He chased one pleasure after another and consumed enormous quantities of alcohol. His relatives finally decided to yield to his craving for change and let him go abroad, where he obtained a position in a branch of the firm. But things didn’t work there either. He flouted the authority of his uncle, who was his chief, annoyed him in every conceivable way, covered him with insults, and led an utterly dissolute life, indulging in every kind of excess. He didn’t do a stroke of work, and after a few months had to be sent home again as a severe alcoholic, in 1899. He was then put into a home for alcoholics, but paid little attention to the regime of abstinence and used his days out for alcoholic and sexual excesses. He stayed there for about six months and then returned home, somewhat better. He did not remain abstinent, but behaved fairly decently until his proposed engagement fell through, which had a shattering effect on him. In despair he took to excessive drinking again, so heavily that he had to be put in the same home for a second time. There he tried as before to dissimulate his use of alcohol, not always successfully. Twice he ran away, the second time to Milan, where he got through several hundred marks in a few days. When his money ran out he telegraphed for more and returned home with a profound moral hangover. When it was suggested to him, in this state, that he should be placed in a closed institution, he readily agreed, and was admitted to Burghölzli on July 22, 1901.

[194] On admission the patient was slightly inebriated, euphoric, very talkative, showing flight of ideas. Told that his mother would visit him the next day, he got excited, wept, declared he was not in a fit state to receive her. In regard to his dipsomania he showed insight, but in regard to its cure he displayed a very shallow optimism. Physical examination revealed nothing but a distinct difference in the size of the pupils. For the rest of July things went well. The patient was always very animated, talkative, cheerful, amiable, showing plenty of social talent, and a sophistication that never went very deep and was at best witty. When out for walks he could talk for hours without stopping, and jumped from one thing to another in his flights of ideas. He expressed opinions on every conceivable subject with the greatest superficiality. He proved to be astonishingly well read in German and English novels of the lighter sort, was always on the go but lacked perseverance. In a short space of time he bought over a hundred books, half of which he left unread. His room was crammed with newspapers, comics, picture postcards, photographs. He took drawing lessons and boasted about his artistic gifts. After three or four lessons he gave up drawing, and the same thing happened with his riding lessons. He realized that his superficiality was abnormal and cheerfully admitted it, even priding himself on this specialty of his: “You see, I’m the most cultured and well-read superficial person,” he said to me once. By the middle of September his patience was at an end. He

became very moody and irritable, suddenly forced his way out, telegraphed home to say he couldn’t possibly remain where he was any longer. He wrote a long letter to the doctors in a huffy, aggressive tone, and several more in the same vein to his relatives. Having returned, after a few days he became quieter and more reasonable. Henceforth he was allowed more freedom, and could go out when he wished. He now began to go out every evening, visiting mostly light concerts and variety shows, and spent almost the entire morning in bed. His mood was continuously elated, he did no work but did not feel the least unhappy about it. This vacuous life continued up to his discharge. He was convinced of the necessity for abstinence, but overestimated his energy and powers of resistance. For his former life he lacked all feeling of shame; could talk with broad complacency about how he had worried his uncle almost sick, and felt no trace of gratitude to him for having taken a great deal of trouble to put him on the right road again. Similarly, he revelled in stories of his drinking bouts and other excesses, although there was nothing in the least praiseworthy about them.

[195] The manic symptoms in this case can be traced back to the high school period, and the purely psychopathic ones to the diphtheria in his twelfth year. The life the patient led from the time he matriculated was quite abnormal and offers a choice of two diagnoses: psychopathic instability or manic mood disorder. Moral insanity, which one might also think of, appears to be ruled out by the wealth of emotional reactions. It is certainly not a case of simple alcoholism, since the psychic abnormality persisted even during abstinence. If we exclude the features that could be grouped under ordinary psychopathic inferiority, we are left with definite hypomanic symptoms: mild flight of ideas, predominantly elated but quite inadequate mood, overactivity without consistency or perseverance. The moral defect is sufficiently explained by the superficiality of mood and the transitoriness of affects.

2

[196] The next case concerns a woman whose life took a similar course, but whose anamnesis, being more detailed, allows us a deeper insight into the

nature of the emotional change.

[197] CASE B, born in 1858, married. Father a neurasthenic eccentric and drunkard, died of cirrhosis of the liver. Mother had heart trouble, died of some mental disease, apparently paralysis of the insane. Nothing known of any severe illnesses in youth. Patient was a bright, uncommonly lively child and a good pupil. From an early age she had suffered under disagreeable conditions at home. Her father was a solicitor, her family of good social standing, but between the parents there was continual strife because the father had an illegitimate liaison. In her eighteenth year, a male secretary employed in her father's business made two violent attempts to rape her, but she did not dare to divulge them to her parents, as the secretary threatened to make devastating revelations concerning her father's affairs. She suffered for years from the memory of these assaults and from the continual sexual molestations of the secretary. Gradually she developed hysterical attacks of convulsions, unaccountable moods, mostly depressions with fits of despair, and to deaden them she began drinking wine. According to her relatives, she was good-natured and soft-hearted, but extremely weak-willed. At 22 she married. Before her marriage she got the consent of her parents to travel part of the way to meet her fiancé, who lived in Italy, but did not return with him at once. Instead, she ran around with him for a couple of days before coming home again. She was married with great *éclat*. The marriage, however, was not a happy one. She felt she was misunderstood by her husband and could never get accustomed to social etiquette. At parties given in their house she secretly slipped away and danced in the yard with the servants. After the birth of a child she became very excitable, partly from weakness, partly because of the visibly increasing estrangement from her husband. From the early days of her marriage she had cultivated a taste for fine wines and liqueurs. Now she drank more and more. On account of her increasing irritability and excitement, her husband sent her on a journey to recuperate. When she returned home she found he had started an intimate relationship with the housekeeper. This was enough to aggravate her already excited condition so gravely that she had to be sent to an institution. She came back after six months and found that the housekeeper, as her husband's mistress, had completely supplanted her.

The consequence was renewed alcoholic excesses. She was then admitted to a Swiss mental home.

[198] The following points are taken from her clinical record. On her admission, May 13, 1888, she went off into loud self-accusations and complained of an inexplicable inner restlessness (which she said had existed ever since the sexual assault). She was soon in a better mood, began comparing the mental home with the private institution she had been in before, praised the latter, complained that she was being boarded as a second-class patient, criticized the regulations. She was extremely labile, at one moment with tears in her eyes, shouting with laughter the next, up to all sorts of tricks. She was extraordinarily talkative and told quite openly, in front of her fellow patients, without the least shame, how she used to make herself drunk. After the alcoholic symptoms had worn off she continued in a very labile mood, garrulous, eager for applause, fond of ambiguous stories, quick at taking words the wrong way, criticizing the doctors and the treatment, "laughing very loudly like a servant girl at quite ordinary jokes," familiar with the staff, socially very entertaining. This emotional lability lasted throughout her stay in the asylum. The diagnosis was alcoholism with moral defect. In November 1890 her husband was granted a divorce, and this was a heavy blow to the patient. She was discharged in December with the best intentions for the future. Her income amounted to 2000 francs a year for five years. She now lived with a woman friend who had a great influence over her. During this time she appears to have been almost completely abstinent. When, in 1895, her income was exhausted, she took a post with her friend in a Swiss asylum. But she did not feel satisfied, got on badly with her superiors, was very upset when a number of escapes took place in her ward, and quit the post after a few months. She then lived alone and began drinking again. Before collapsing altogether, she was able to make up her mind to visit a clinic of her own accord, and was admitted to Burghölzli on October 19, 1895.

[199] On her admission she was much the same as on the admission reported above, only less inebriated. The initial depression quickly disappeared, and she soon unbosomed herself in exuberant letters to her friend. She was a "creature of moods," "never able to hide her feelings,"

allowing herself to be entirely ruled by the mood of the moment. She was extremely active and adapted herself quickly, “cheerful, temperamental, always ready with a bad joke,” sometimes bad-tempered, often carrying on in a rather sentimental way. Her behaviour at concerts in the asylum was ostentatious; instead of singing, she would warble with full-throated laughter. In 1896, on one of her days out, she suddenly got engaged to another patient, also an alcoholic. In July 1896 she was discharged. The medical report emphasized that her alcoholism was caused by her moods, which completely dominated her. Further, that her emotional condition was now more evenly balanced, but that there was still a “congenital lability of mood and great emotional excitability.” After that she lived “in sin” with her fiancé, who soon had a relapse and started her off drinking again. He was put in a home, and she, left to herself, tried to make a living in the grocery trade, but without much success. Once more she took to heavy drinking, got drunk daily, frequented taverns of ill repute, and on one occasion tore off her clothes in a frenzy of excitement, so that she stood there in her petticoat. She often turned up at the tavern dressed only in petticoat and raincoat. In November 1897 she was brought back to the asylum. On admission she had an hysterical attack with symptoms of delirium tremens. Then followed deep depressions, which lasted in milder form until January 1898, though this did not prevent her from showing great liveliness on festive occasions. Later she became touchy, flaunted her superior social position before others, was at times erotic, tried to flirt with a male patient, singing him sentimental songs from a distance. She was full of optimistic plans for the future, started to learn typewriting and helped in the anatomical laboratory. In March 1898 she suddenly went out and got mildly drunk, and received a reprimand which threw her into a blind rage. Next day she was found in an extreme stage of intoxication, and it turned out that she had made herself drunk in the laboratory with 96% alcohol. She was wildly excited, quite unapproachable at first, uttering threats; then manic, with flight of ideas, pressure of activity, eroticism, and devil-may-care humour. After a few days she was the same as before, unable to adapt to regulations, flirting with a manic patient at a concert. Periods of boisterous merriment. Discharged on October 11, 1900, to take up post as a housekeeper. Worked extraordinarily well and was much appreciated for her continual gaiety and sociability. From a letter written at this time we extract the following passages, which are typical of her extreme self-confidence, exaggerated language abounding in forceful expressions, and her elated mood:

[200] The everlasting mistrust, the everlasting disbelief of these pessimists in a final moral cure, saps your strength and breaks your courage. You see yourself abandoned by others and finally you abandon yourself. Then you try to deaden your torments of soul and seize on any and every means that deadens—so long as there's spirit in it. Thank God I no longer need this deadening now. Are you pleased with me? Do you believe in my leonine strength?—!! …

[201] My talent for educating children is a fact which neither the scepticism of Dr. X nor the shrewdness of Dr. Y can abolish.…

[202] I am so tired in the evenings that my head throbs, as though it had been used for a drum in the Basel carnival. Under these circumstances you must bear kindly with me if letters from my hand turn into birds of paradise and the inclination to ballet dance in ink is at its last gasp.

[203] In July 1901 she went down with influenza, and her employer inadvisedly gave her wine as a tonic (!), whereupon she got a bottle of wine sent up every day. On July 7, she was readmitted to Burghölzli for delirium tremens, having lately drunk methylated spirits and eau de cologne. Now and then she seemed to have deep depressions with a sentimental tinge, but they were never so bad that she could not be provoked into wildly gay laughter. At a concert in August her behaviour was quite manic; she adorned herself with three huge roses, flirted openly, showed motor restlessness, behaved extremely tactlessly with the others. No insight afterwards. Her "excitability reached the highest degree of mania" (July 1901). At a music rehearsal in the room of an assistant doctor she was "extremely vivacious and talkative, erotic and provocative." She was sexually very excited at this period, but sometimes depressed. She dashed off her copywork in a careless way, wrote pages of sentimental scribble showing flights of ideas. She could be roused to all kinds of activity, but her energy invariably flagged. Very sensitive, reacting to censure with deep depression, all emotional reactions

extremely labile and immoderate. She had no insight into her lability, greatly overestimated herself and her powers of resistance, had an inflated sense of her personal value, and often made very disdainful remarks about other people. She felt that she still had “a task in front of her,” that she “was destined for something higher and better,” that not her inferiority but her unfortunate circumstances were to blame for her degeneration. From August 1902 to April 1903 she followed a weight-reducing course, and towards the spring a more stable depression supervened, during which she took more pains with her copywork than before.

[204] The first psychopathic symptoms in this hereditarily tainted patient showed themselves from her eighteenth year in the form of marked hysteria resulting from sexual traumata. Indications of some emotional abnormality apart from the hysteria are present from the age of *22*. After her thirtieth year we have an accurate clinical history in which superficiality and emotional lability are already established. Besides alcoholism, a moral defect was diagnosed (1888). In 1896, the alcoholism was recognized as dependent on her emotional lability. In the course of years the manifest hysteria entirely disappeared except for a few symptoms (sentimental tone of the depressions), but the emotional abnormality remained stable. The periodic depressions were always of short duration and never so deep that they could not be banished by a joke. The only depression of longer duration, which had a decidedly improving effect on the patient, occurred under the influence of the reducing course and can therefore be regarded as a specific effect of this treatment. Depressions under such a treatment also occur with normal persons. The patient’s depressions often had a reactive character, especially to censure, and were then merely excessive reactions to a depressing stimulus. Spontaneous exacerbations of stable symptoms were never observed with certainty; in most cases they were excessive reactions to the effects of joy or alcohol. The patient was decidedly manic when drunk. In her normal state we find a mild flight of ideas, which expressed itself particularly clearly in her writings; a predominantly elated mood with optimistic outlook, often indicative of her exaggerated self-esteem; great lability of pleasure/pain affects;

marked distractibility. Her manic over-activity showed itself as a rule merely in her extreme vivacity and talkativeness, but it only needed some kind of festivity to produce an immediate increase of motor activity. The dependence of alcoholism, and of moral inferiority in general, on emotional abnormality is much clearer here than in the first case.

[205] The third case concerns a patient who was chiefly remarkable for her social instability.

[206] CASE C, born in 1876, nurse, unmarried. Heredity: father a drunkard, died of carcinoma of the liver. Step-sister (by the same father) epileptic. Patient had no severe physical illnesses in youth. Clever at school, also got good marks for behaviour, with few exceptions. Once when she got bad marks for arithmetic, she tore up the report under the teacher’s eyes. Once wrote an anonymous letter to the school administration, denouncing certain teachers for assigning too much work. Once she ran away from school for two days. She was a very lively child, passionately fond of reading novels (often half the night). At 16 she left school and went to her sister’s to learn how to be a seamstress. But she did little work, read most of the time, never obeyed her sister, quarrelled with her after six months, and then took up another apprentice post, where she stayed only nine months instead of the required two years. She was quick to learn though not very diligent, was usually very merry, but sometimes irritable. Though “good-natured,” she “never took anything much to heart.” She was “burning with travel fever” and made up her mind to go to Geneva. There she found a job as an apprentice seamstress for a year, remained for the full period, but took occasional time off, paying her employer for the day. Afterwards she returned home. During this period her diet consisted almost entirely of sweets, of which she sometimes consumed five francs’ worth a day. Although it finally sickened her, for a long time afterwards she felt impelled to buy chocolates whenever she passed a confectioner’s. She would then give them to children in the street. She borrowed money for her passions in the most frivolous way from everybody, often just took it from her sister or bullied it out of her. After about six months she induced a relative to take her to America. Stayed a month in Chicago without working. Then she worked at a clothes shop, ran away four days later without giving notice. She then

changed her job ten times in succession, staying a few hours or at most a couple of days in each of them. Finally found a job that suited her, as a companion. Became ill six months later with stomach ulcer; returned to Switzerland. She left a job as receptionist at a hotel after five days because of a quarrel with her employer, and went back home. A few weeks later she took a job as a housemaid, but got "sick of it" after eight months. She "could only stay in a job until she knew the country and the people, then something else had to come along." Then she worked as a student nurse in a hospital in Bern. "Sick of it" after five months, went to another hospital, four months later became ill again with stomach ulcer, spent several months ill at home. At this point she started an illegitimate relationship with the dissolute son of a neighbour. On recovering from her illness, she worked as a shopgirl in Zurich. Spent considerable sums of money on herself and her friend, whom she supported financially. She borrowed money everywhere and left her father and sister to pay her debts. As a result, she was sent to a faith-healing institution for a cure, where she stayed for six months, working fairly well; then another four months as a maid. She started another intimate relationship, but soon got sick of her lover. Then seven months as a wardress in an institute for epileptics, followed by five months as a children's nurse in a private house, which she left because of quarrels with one of the maids. She then betook herself to her late lover in W., made a violent scene but was finally reconciled. After that she got another job as a maid in Schaffhausen for a fortnight, then for two days in Bern, for some weeks in Zurich, for another four weeks in Bern, then again for a short time in Zurich, then for two months as a nurse in a lunatic asylum, then again for a few days in W., where she ran through her earnings at the hotel and started quarrelling again with her lover. After renewed reconciliation, she returned to Zurich, but soon fell out two more times with her lover, took another job for two months, then went to Chur "for the fun of it," then back to W., in order to make another scene with her lover, then returned to Zurich for a few days, only to go immediately afterwards to W. and make a second and this time final scene with her lover. After that she took a job as a children's nurse in the Valais, where she stayed two and a half months. She became ill again with stomach ulcer and returned to Zurich via W. As she got out of the train at W. the first person she ran into was her lover, which annoyed her so much that she took the train straight back to Zurich. On arrival in Zurich, however, she regretted her sudden decision and immediately seated herself in the train back to W. Alighting on the platform at W., she regretted this decision too and rushed back to Zurich. (The distance between Zurich and W. is an hour and a half by rail.) On returning from W. after one of her quarrels, she went to a hotel with an unknown man whom she picked up at the station in Zurich and spent the night with him. With another she started an erotic conversation and apparently followed him even into the toilet, causing a public scandal.

[207] Wherever she worked she was liked, as she was constantly busy and a pleasant companion. She was never quiet, always on the go and excitable. Lately the excitement increased visibly, she also talked much more than before. She had never saved any money; what she earned she spent at once and incurred debts everywhere.

[208] On the recommendation of Professor M., the patient was admitted to Burghölzli on April 2, 1903. The report emphasizes the following points: "The patient suffers from a mild degree of maniacal excitement. The outward cause may be considered to be an affair with a young man which came to nothing. For several weeks the patient was expansive, unstable, irritable; she is excessively open-handed, sleeps little at night, cannot bear to be contradicted. Her mood is elated. She is talkative, occasionally showing flight of ideas. She cannot be kept at home because of her expansiveness, she starts something new every minute, and wants to go to W. in order to wreak her vengeance on her former fiancé."

[209] She had a lively, intelligent expression of face, talked a great deal. Continuous motor restlessness when talking; in ordinary conversation no very noticeable flights of ideas; these only showed more clearly during longer recitals. She was very elated, very erotic, flirting and laughing a great deal; very labile, weeping easily at the memory of unhappy experiences; liked to sulk ostentatiously, and once made a violent scene when the doctor refused to visit her alone in her room, threatened suicide, so that she had to be removed for a while to the observation room. Soon afterwards she was as euphoric as ever. She was very frank and enjoyed

telling of her adventures, but was incapable of putting them down on paper in an orderly fashion. An autobiography still remains to be attempted after several false starts. She expressed a strong desire to go out, but still harboured thoughts of vengeance on her ex-fiancé, threatened to shoot him. Had all sorts of adventurous plans for the future, and once urgently requested to be allowed out in order to answer a newspaper advertisement for an animal trainer, asserting proudly that she did not lack courage. In addition, she had intensive plans for marriage. She took the disorderly life she had lived very lightly, and was convinced that things would go better in future. She showed slight insight *into* the excitement of the last few weeks before her admission. No major depressions or excited states were observed, and no deterioration of the normal state except the present one. Slight increase of excitement during her periods.

[210] In my account of this case I have purposely given a complete chronicle of the changes in social position in order to illustrate the extraordinary instability and restlessness of the patient. Over a period of eleven years, she changed her job no less than thirty-two times, in the great majority of cases simply because she was "sick of it." So far as one can rely on the anamnestic information, the abnormal emotional state can be followed back into childhood. Apart from the menstrual cycle no periodicity was discoverable. Depressions never seemed to arise spontaneously, but were merely the outcome of circumstances. There was no alcoholism, only an enormous abuse of sweets. The findings—mild flight of ideas, talkativeness, predominantly elated mood, lability, distractibility, pressure of activity, eroticism— all bear out the diagnosis of manic mood disorder and explain the patient's erratic and morally defective career.

4

[211] The fourth case was under investigation on a charge of theft and was certified by me as of unsound mind, the intensity of manic symptoms being of so high a degree that even "partial responsibility" seemed to me out of the question.

[212] CASE D, born 1847, painter. Heredity: father an eccentric person, intelligent, very lively, frivolous, always in a merry mood, went in for politics and litigation, neglected his business and his family, drank and gambled, lost his property and fortune, until he finally came to the poorhouse. First brother intelligent and gifted, head full of ideas, interested in social and political problems, died in poverty leaving a pile of debts. Second sister very extravagant, died in dire poverty. Third brother a moderate drinker, but able to support himself and wife. Fourth brother led a profligate life in every respect, a notorious liar, very much come down in the world, living on poor relief. One son of a normal brother was a notorious scrounger and sot. Patient had no serious illnesses in youth. A lively child, alert and intelligent; excellent school reports. Was apprenticed after leaving school; worked very industriously for the first year, clever, made progress. In the course of the second year he changed, started drinking, neglected his work, extravagant. Remained four years in the same job, then took to roaming. His dissoluteness increased, his work grew more and more uneven and careless, and by way of contrast he developed a "terrific opinion of himself," boasted of his cleverness and gifts, always passing himself off as something quite extraordinary. His roamings began at 19. He never stayed anywhere for longer than a few months, was always drinking, dissatisfied, no master was good enough for him, always had his "special ideas," wanted to "be appreciated," thought "everything should be to his liking," was always "worked up," frequently quit his job without giving notice, sometimes without even collecting his wages. In 1871 he returned home utterly destitute, looking like a tramp. Despite that, he bragged endlessly and told boastful stories about himself and his successes. He remained for some time at home, worked eagerly, "always in a hurry." Suddenly his elated mood changed, he became irritable, cantankerous, grumbled about the work, his work-mates, former masters, etc., sometimes getting into a rage and "acting like the devil." Now as before he indulged in drink, and the more he drank the more excited he became, giving vent to an unstanchable stream of talk. After a fortnight he suddenly packed his things, set forth on his wanderings again, and finally, in 1873, came to Paris. He found no work there because of the slump, and was sent home again by the authorities after five weeks. In 1875 he went to Nuremberg.

According to the report of his employer there, he was a very skilful and efficient worker, but had to be dismissed on account of drunkenness. Because of acute manic excitement he had to be kept in confinement for a few weeks, and as no real remission ensued, he was packed off to Switzerland. He was admitted to Burghölzli on March 21, 1876.

[213] The patient was elated, excited, laughing away to himself, showed flight of ideas, made bad jokes, heard voices that told him funny stories, showed immense self-esteem. No essential change subsequently occurred except for a quieting down and cessation of the voices. The illness was taken for mania, and the patient was discharged as cured in August 1876, although at the time of his discharge he certainly did not give the impression of being a normal person. He then began his old wandering life again. He roamed round Switzerland like a vagabond; in November 1876, as a result of great privations and severe cold, he found himself in a delirious state in which it seemed to him that "he was the pope and had ordered a huge dinner." In this state he tried to draw 5000 francs at the post-office and was arrested; on taking food he suddenly became clear again. In 1882 he married. The marriage remained childless. His wife had four or five abortions. He stuck to her for almost a year; then the wanderings were resumed and he stayed with his wife only off and on. In 1885 he found himself in great straits, and in desperation conceived the plan of poisoning himself and his wife. But he was afraid to carry it out, so he fell back on stealing. Up to the beginning of 1886 he committed a series of thefts, was arrested, and in view of his doubtful mental condition was referred to the doctors in St. Pirminsberg for a medical opinion. The following points were emphasized in the report:

[214] The patient was in a continuous state of elation, with heightened self-confidence, amounting at times to real megalomania. He delighted in making mysterious allusions to his importance: "Great things are impending, here in the madhouse sits the founder of God's kingdom on earth." He composed an eighty-page opus intended for the press, largely incoherent in content, through which there ran like a red thread his unbounded glorification of himself. In it he addressed himself rhetorically to the pope, deeming himself his equal in infallibility, also to Christ, spoke of himself as a new Messiah, compared himself to Hercules

and Winkelried, etc. Occasionally he went into real ecstasies, in which he wrote things like: “The greatest artist of all times past and to come shines the shoes of the unfortunate, polishes the floor in St. Pirminsberg. As is the son, so is the father and vice versa.—Hurrah for Helvetia!!! O stone of the wise, how thou shinest! O D—(his own name), what brilliance! Your God, O my companions, has the heart of a child, the voice of a lion, the innocence of a dove, and the appearance of one of you!” During his stay in the asylum the composition of these pieces formed his main occupation. He wrote several pages a day, and when his paper ran out he would sing patriotic songs for hours on end in a raucous voice. He was always very talkative, spoke in dialect, but when he really got going he fell into a literary style. His thought processes were orderly, but with a tendency to digression and detailed description. His language abounded in choice expressions, with a preference for foreign words, though these were generally used correctly. In keeping with his exaggerated self-esteem he always held himself aristocratically aloof from the other patients; the warders he snubbed, whereas he was always very friendly with the doctors. His situation did not worry him, he lived cheerfully from day to day, full of the greatest hopes for the future. He never showed any insight into his illness. Once he was in a particularly bad mood for several days, very irritable, suspicious, reserved, but occasionally cursing and swearing about the asylum. The diagnosis was “periodic mania, which might pass over into insanity.” The thefts were put down to unsoundness of mind.

[215] On October 2, 1886, the patient was transferred to Burghölzli. Until December his state was the same as in St. Pirminsberg. At the beginning of December he quieted down a bit; the earlier symptoms continued but were less intense. He was given some painting to do in the asylum. Among other things he painted the asylum chapel; it was subsequently discovered that between the veins of the marble he had drawn little figures of devils and also a not unskilful caricature of the asylum’s priest. He was discharged on February 25, 1887. Even during this quieter phase he still produced the same old ideas, held forth with great pathos on his vocation as a reformer and world improver. After his discharge he resumed his wanderings in Switzerland, working a bit but never staying

more than a few months in the same place. In 1891 he stole a great deal of food and was sentenced to *six* months in the workhouse. In 1893 he got a year for the same reason. In 1894 he was charged with stealing 700 francs. From the fourth day of his detention on, he heard voices whispering outside his door, and thought he could recognize the voice of one of his nieces, saying: “You will be repaid.” Six days later he was released. At home the hallucinations persisted for another day and then suddenly vanished. In 1895 he was sentenced to two years in the workhouse for theft. In January 1895 he was sent to the penitentiary. According to the statements of officials there, the patient “had a screw loose” from the beginning and soon aroused suspicions of mental disorder. He accused the officials, quite without reason, of swindling. In solitary confinement he covered the walls with senseless daubs, asserting that he was a great artist. At night he was restless, talking loudly to himself about his “daily occupation.” Now and then he was very irritable. On August 19, 1895, another medical report was made on him. The following points were emphasized: “The condition of the patient is much the same as that described in 1886 in the report from St. Pirminsberg. He showed manic excitement, flight of ideas, extraordinary elation, and self-esteem, boasting of his capabilities, his physical prowess, saying that he had known for 25 years how, ‘by means of a certain substance, as with a breath, everything could be decked in the most gorgeous, dazzling colours’; he could ‘change a dog into the most beautiful golden scarab in the twinkling of an eye.’ ” He came out with a lot of similar stories. On November 9 he was moved to Burghölzli. His condition was the same as in the penitentiary. He gave more or less logical reasons for his exaggerations. For instance, he got his gilding effects by brushing over with the right colour; gave up his plan for world improvement after he had seen how incorrigible the world was. His behaviour varied as before; mostly he was elated and excited, but intermittently he was irritable, with stormy moods. Though he quieted down somewhat, his condition remained the same until his discharge on January 16, 1897.

[216] In the weeks preceding his recent arrest he wandered round the neighbourhood of his home village and spent the nights in a barn, the walls of which he scribbled over with verses and sayings. His clothes

were in rags, his shoes were tied to his feet with string. Between September 13 and October 3, 1901, he committed three burglaries with theft at night, taking food, drink, tobacco, and clothes. He stated that on the occasion of one of these thefts he was very agitated because, while in the cellar, he heard a voice saying: “Go down quickly and leave something for me too.” He was arrested on October 8, 1901. At the first hearing he pleaded guilty. He was sent to us for observation on November 1, 1901. During his stay his behaviour was found to be unchanged. On admission he was very cheerful, composed, sure of himself, greeted his old acquaintances cordially, was very talkative and excitable, replying at great length to every question and tacking on remarks and stories showing flight of ideas. He recounted his life story in a coherent manner, keeping fairly well to the facts. At night he slept little, mostly lay awake in bed for hours worrying about “scientific” problems. He had theories about the origin of meteorites, about the transport of dead bodies to the moon, about airships, about the nature of the brain and mental processes, etc. He worked industriously and quickly, often talking to himself or keeping up an accompaniment of animal noises—miaowing, barking, cackling, crowing. When walking about the ward he sometimes went at the run, or even on all fours. At work in the fields he was talkative, enjoyed teasing others, adorned his hat with roots and leaves of vegetables. He conceived his ideas at night and put them down, elaborately and extensively, on paper. His compositions were closely written, looked clean and neat, and except for the copious use of foreign words the spelling was correct. They revealed an erudition of sorts, a very good memory, distinct flight of ideas, with great pressure of speech and forceful expressions. Prose pieces in literary style or in dialect were jumbled together with quotations from Schiller, verses (his own and other people’s), sentences in French, always with a connecting thread of meaning which, however, did not go very deep. No uniform, comprehensive idea could be found in any of his writings, except for an intense subjective feeling of his own value and an unbounded self-esteem. The language he used was sometimes full of deep pathos, sometimes deliberately paradoxical. He was ready to discuss his ideas, did not cling to them obstinately, but dropped them in order to turn to new problems. It was even possible to talk him out of his meteorite theory and to wring from him the admission that “even the greatest scholars have been mistaken.” He would expatiate on all kinds of moral and religious questions, and displayed a lyrical and almost religious feeling—which did not prevent him, however, from blaspheming and making a laughing-stock of religious practices. Once, for example, he performed a gross travesty of the Mass. He said he was not born to work for his living, had better things to do, and must wait for the time when all his grand ideas would be realized, when he would create educational establishments for the young, a new system of world communications, etc. He had great hopes of the future, by comparison with which all thought of the actual present vanished. Despite this keen expectation he had no clear picture of the future in his mind, could only adumbrate vague and fabulous plans which were mostly concocted on the spur of the moment. But he was convinced that “all would come in good time,” and hinted that he would perhaps live longer than other *men* in order to accomplish his work. His earlier statements that he was the Messiah, “the founder of God’s new kingdom,” he corrected as symbolisms; he was only comparing himself to the Messiah and not asserting that he had any more intimate connection with him or with God. In the same way he disclosed that what had previously been taken for delusional ideas were exaggerations or vivid comparisons.

[217] Occasionally there were angry moods, usually provoked by insignificant trifles which at another time would not have been followed by an angry reaction. For instance, he once created a great disturbance at 3 o’clock in the morning, shouting, cursing, and barking like a dog, so that he woke the whole ward. As usual, he had not slept properly after midnight and was annoyed by the snoring of a patient. He justified the uproar by saying that if others were permitted to disturb him with their snoring, then he was permitted to make a noise at night too.

[218] This patient came of an abnormal family, and at least two of his close relatives (father and brother) seem to have had the same mental constitution. The picture of manic mood disorder developed after puberty and had persisted with occasional exacerbations throughout his life. Here again we find a number of symptoms of psychic degeneracy apart from the specifically manic ones. The patient was only an occasional

alcoholic, probably from lack of money and also because, being everlastingly occupied with his enormous afflux of ideas, he lacked real leisure for drinking. His ideas show certain affinities with “inventor’s paranoia,” but on the one hand he lacked the stability and toughness of the paranoiac, and on the other hand his ideas were not fixed and incorrigible, but were more in the nature of inspirations that came to him from his elation and exaggerated self-esteem. The hallucinatory episodes that are mentioned several times in his history cannot easily be related to any known clinical picture; one of them seems to have been an effect of exhaustion, another an effect of imprisonment, a third an effect of excitement. Magnan regards them as “syndromes épisodiques des dégénérés.” Although we know that “prison complexes”[7] can occur in all sorts of degenerate subjects, we are unable to point to any particular underlying psychosis. Again, in our patient we see the delirious states passing quickly and without after-effects, for which reason they may best be regarded as syndromes of degeneracy.

[219] Here too we find periodic mood disorders in the form of pathological irritability. Once (1885) there was a deeper depression, when the patient toyed with the idea of suicide. Despite careful investigation we were only able to discover this one depression, and it is not even certain whether it lasted for an appreciable time or whether it was a sudden change of mood, such as usually occurs with manics. Apart from these few features, which do not belong absolutely to the picture of mania, the case offers all that is necessary for a diagnosis of manic mood disorder. The patient showed distinct flight of ideas, a profusion of fanciful thoughts and words; his predominating mood was not merely cheerful and carefree, but manically elated, expressing itself all the time in manic tricks and immense pressure of activity, which occasionally amounted to purposeless motor hyperactivity. His intelligence was good, and he was capable of judging his situation perfectly correctly, but the next moment his ideas of grandeur returned, and he was swung into them by the force of his overproductive pleasure feelings. He led the most miserable life as a vagabond, roaming about the countryside summer and winter, half starved, sleeping in barns and stables, yet in flagrant contrast with reality was forever brooding on lofty schemes of world reformation.

Significantly, his non-recognition by the rest of humanity was of no concern to him, as it would be to a paranoiac. His continual pleasurable excitement helped him even over this adversity. From all this we see how very much the intellect was taken in tow by the emotions. He was not really convinced of his ideas, for he did not mind correcting them theoretically; but he hoped for their fulfilment, in contrast to the paranoiac, who hopes because he is convinced. This case reminds one forcibly of those miserable lives lived by poets and artists who, with small talent and indestructible optimism, eke out a hungry existence despite the fact that they possess quite enough intelligence to realize their social inadequacy in this form, and enough talent and energy, if applied in other directions, to do good and even outstanding work in an ordinary profession. The patient can also be compared, up to a point, with those individuals whom Lombroso describes as "graphomaniacs." They are psychopaths who, without being paranoid or feeble-minded, overestimate themselves and their ideas in the most absurd way, play about with philosophical or medical problems, write vast quantities of rubbish, and then ruin themselves by having their works published at their own expense. The defective critical faculty of such persons is often due not to feeble-mindedness, for they can sometimes detect the mistakes of their opponents very well indeed, but to an incomprehensible and exorbitant optimism which prevents them from seeing objective difficulties and fills them with invincible hopes of a better time to come, when they will be justified and rewarded. Our patient, however, reminds us also of numerous "higher imbeciles" and crackpot inventors whose feeble-mindedness is confined to lack of criticism of their own particular quirks, and whose intelligence and efficiency in other departments are at least average.

[220] It should be emphasized that in the four cases we have reported the intelligence was good throughout, in the first and second cases even very good, in flagrant contrast to the outward conduct of life, which was extraordinarily inept. It is a contrast also met with in moral insanity. No doubt the majority of cases of moral insanity mentioned in the literature were more or less feeble-minded, but there can also be no doubt that in the majority of cases the feeble-mindedness is not sufficient to explain

their social incapacity. One gets the impression that the intellectual defect is more or less irrelevant and that the main emphasis falls on emotional abnormality. And here it is not so much a lack of ethical feelings that seems to play the chief role as an excess of instinctual drives and positive inclinations. A simple lack of ethical feelings would be more likely to favour the development of a ruthless, coldly calculating “mauvais sujet” or criminal, rather than one of those pleasure-seeking individuals, instinctively up in arms against any form of social restriction, who unthinkingly fly off the rails at every point, often so brainlessly that the veriest imbecile could see the senselessness of it. Tiling[8] has recently pointed out that the main element in the picture of moral insanity is an excessively sanguine temperament,[9] which serves as too mercurial a basis for the intellectual process and fails to give it the necessary continuity of feeling-tone, lacking which there can be no arguments and no judgments capable of exerting any influence on the decisions reached by the will. A great deal has already been said and written about the relation between intellect and will. If there is any field of experience that teaches the dependence of action upon the emotions, that field is certainly psychiatry. The inferiority of the intellect as compared with instinctual impulses in regard to voluntary decisions is so striking that the daily experiences even of a psychologically minded, amateur psychiatrist like Baumann[10] impel him to remark that the specific activity of thought is always preceded by something “primarily characterological,” which provides the necessary disposition for this or that action. Here Baumann is simply voicing Schopenhauer’s “operari sequitur esse” in other terms. What is “primarily characterological” is, in the wider sense, the feeling-tone, whether it be too little or too much or perverse; in the narrower sense it is the inclinations and drives, the basic psychological phenomena which make up man’s empirical character, and this character is obviously the determining factor in the actions of the great majority of people. The role played by the intellect is mostly a subsidiary one, since all it does at best is to give the already existing characterological motive the appearance of a logically compelling sequence of ideas, and at worst (which is what usually happens) to construct intellectual motives afterwards. This view has been expressed in general and absolute terms by Schopenhauer,[11] as follows: “Man ever does what he wills, and does so by necessity; that is because he *is* what he wills; for from what he is there follows by necessity everything he will ever do.”

[221] Even if we admit the fact that numerous decisions are mediated or first considered by the intellect, we should still not forget that every link in a chain of ideas has a definite feeling-value, which is the one essential thing in coming to a decision and without which the idea is an empty shadow. But this feeling-value, as a partial phenomenon, underlies any changes in the whole sequence, which in the case of mania results in Wernicke’s “levelling-down of ideas.” Consequently, even the purest intellectual process can reach a decision simply through feeling-values. Hence the prime motive for any abnormal action, provided that the intellect is fairly well preserved, should be sought in the realm of affect.

[222] Wernicke[12] regards moral insanity as a distant parallel to mania, supposing the elementary symptom to be a levelling-down of ideas. In most cases he finds an inner unrest and irritable moods, but omits all the other, equally important manic symptoms like flight of ideas, pressure of talk, morbid euphoria, etc.

[223] In surveying the literature on morally defective persons one cannot fail to be struck by the emotional excitability and lability so frequently reported.[13] It would perhaps be worth while, when investigating the morally defective, to direct attention mainly to this emotional abnormality, or rather lability, and to consider its incalculable effects on the intellectual processes. In this way it might be possible to shed new light on cases which till now have been judged only from the standpoint of moral defect, and to regard them rather as examples of emotional inferiority in the sense of a relatively mild or serious manic mood disorder. The greatest attention along the lines suggested would be claimed by the cases of moral insanity which follow a periodic or cyclic course with “lucid intervals” and paroxysmal exultations.

[224] To sum up:

1. Manic mood disorder is a clinical condition that belongs to the field of psychopathic inferiority, and is characterized by a stable,

hypomanic complex of symptoms generally dating back to youth.

2. Exacerbations of uncertain periodicity can be observed.

3. Alcoholism, criminality, moral insanity, and social instability or incapacity are, in these cases, symptoms dependent on the hypomanic state.

[225] In conclusion, I would like to thank my chief, Professor Bleuler, for kindly allowing me to make use of the above material.

IV

A CASE OF HYSTERICAL STUPOR IN A PRISONER IN DETENTION

A CASE OF HYSTERICAL STUPOR IN A PRISONER IN DETENTION[1]

[226] The following case of hysterical stupor in a prisoner in detention was referred to the Burghölzli Clinic for a medical opinion. Apart from the publications of Ganser and Raecke, the literature on cases of this kind is very scanty, and even their clinical status seems uncertain in view of Nissl's criticisms.[2] It therefore seems to me of interest to put such a case on record, particularly as the special clinical picture it presents is of considerable importance for the psychopathology of hysteria in general.

[227] The patient, Godwina F., was born May 15, 1854. Her parents were stated to have been healthy. Two of her four sisters died of consumption, another died in a lunatic asylum, the fourth was normal. One brother was also normal and very steady-going. The second brother was Carl F., an habitual criminal. Her two illegitimate daughters were both healthy. Nothing was known of any previous major illnesses. The patient came of poor circumstances; she began work in a factory at the age of 14. At 17 she started a love affair, had her first illegitimate child at 18, her second at 28. She was entirely dependent on her lover, who provided her regularly with money. She alleged that three years earlier she had received from him some 20,000 marks, which she quickly spent. Consequently she got into financial difficulties, let her hotel bills pile up, and then left the hotel, repeatedly promising the proprietor that she would pay as soon as she got the sum due–10,000 marks–from her lover. Suspected of theft, she was arrested on May 31, at 5 P.M. At the preliminary hearing on the same day, and on the following days, she conducted herself quite correctly, and her behaviour in custody was altogether quiet and respectable.

[228] Her daughter stated that the patient had lately been irritable and depressed, which was understandable enough in view of her difficult

situation. Otherwise nothing abnormal could be ascertained.

[229] When, on the morning of June 4, 1902, the cell was opened at 6:30, the patient was standing "rigid" by the door, came up to the wardress "quite rigid" and furiously demanded that she should "give back the money she had stolen from her." She waved away the food that was put before her, remarking that there was "poison in it." She began to rage and shout, threw herself about in the cell, kept on asking for her money, saying that she wanted to see the judge at once, etc. At the call of the wardress, the jailer came with his wife and assistant, and together they tried to calm her down. Apparently there was a fairly lively scene; they held her by the hands and (according to the wardress) also "shook" her. They denied hitting her. The patient was then locked up again. When the cell was opened again at 11 o'clock the patient had torn the top half of her clothes to shreds. She was still very worked up, said the jailer had hit her on the head, they had taken the money she got from her husband, 10,000 marks, all in gold, which she had counted on the table, etc. She showed an acute fear of the jailer.

[230] During the afternoon the patient was quieter. At 6 in the evening the District Medical Officer found her totally disoriented. The following symptoms are worth noting: almost complete lack of memory, easily provoked changes of mood, megalomaniac ideas, stumbling speech, complete insensibility to deep pin-pricks, strong tremor of the hands and head, her writing shaky and broken. She fancied she was in a luxury hotel, eating rich food, that the prison personnel were hotel guests. Said she was very wealthy, had millions; that during the night a man attacked her, who felt cold. At times she was excitable, screaming and shouting gibberish. She did not know her own name and could say nothing about her past life and her family. She no longer recognized money.

[231] On the way to the asylum she was extremely nervous and frightened, started at every little thing in an exaggerated way, clung to the attendant. She was admitted at 8 P.M. on June 4.

[232] The patient was of medium height, physically well nourished. She looked exhausted and haggard. Expression of the face was nervous and tearful, as if she felt utterly helpless and hopeless.

[233] Her head, tongue, and hands trembled. Depression in region of fontanelle; circumference of head 55 cm.; biparietal 15 cm.; occipitofrontal 18.5 cm. Pupils reacted normally to light and to accommodation. Gait rather unsteady. No ataxia, no Romberg sign. Reflexes of forearm and knee- and ankle-jerks brisk; pharyngeal reflex present.

[234] *June 5.* Patient passed a quiet night. Today she kept to her bed, quiet and listless. Ate decently, was clean in her habits. No spontaneous sign of affect; facial expression indicated a mood of nervous discontent without any strong affects. She looked at me with a helpless gaze, jumped at all sudden questions and quick movements. Her mood was very unstable and depended very much on the facial expression of her questioner. A serious face made her cry at once, a laughing face made her laugh, too, and to a stern face she reacted with instant fear, turned her head away, buried her face in the pillows, saying: “Don’t hit me.”

[235] There were no symptoms of any major restriction of the field of vision. (Accurate tests were impossible owing to her psychic condition.) Skin sensibility, or rather sensibility to pain, exhibited peculiarities: at the first examination there was total analgesia on the legs and feet for deep, unobserved pinpricks, with normal sensibility on the head and arms. After a few minutes the picture changed completely: total analgesia on the left arm and normal sensibility on the lower limbs—the very places where the opposite condition had been observed shortly before. The analgesic areas varied without rhyme or reason, being apparently independent of suggestion (though this cannot be ruled out with certainty). The striking thing was the patient’s behaviour during this examination: she resisted it, but did so in an impersonal way, not paying any attention to what I was doing, even when I intentionally administered the pricks quite openly, under her very eyes. *Rather, as if consciously denying the real situation, she looked for some unknown cause of the pain in her nightgown or in the bedclothes*.

[236] The following conversation then took place:

Where are you? — *In Munich.*

Where are you staying? — *In a hotel.*

What time is it? — *I don’t know*.

What’s your name? — *Don’t know*.

Christian name? — *Ida*. (This was the name of her second daughter.)

When were you born? — *I don’t know*.

How long have you been here? — *Don’t know*.

Is your name Meier or Müller? — *Ida Müller*.

Have you a daughter? — *No*.

Surely you have! — *Yes*.

Is she married? — *Yes*.

Whom to? — *To a man*.

What is he? — *Don’t know*.

Isn’t he the director of a factory? — *Yes, he is*. (Wrong answer.)

Do you know Godwina F.? — *Yes, she’s in Munich*.

Are you Godwina F.? — *Yes*.

I thought your name was Ida Müller? — *Yes, my name’s Ida*.

Have you ever been to Zurich? — *Never, but I’ve stopped with my son-in-law*.

Do you know Mr. Benz? (The son-in-law.) — *Don’t know Mr. Benz, never spoken with him*.

But you’ve stopped with him, haven’t you? — *Yes*.

Do you know Carl F? (Her brother.) — *Don’t know him*.

Who am I? — *The headwaiter*.

What is this? (A notebook.) — *The menu*.

Tell me the time. (I showed her my watch, which said 11.) — *One o’clock*.

What is three times four? — *Two*.

How many fingers is this (5)? — *Three*.

No, look carefully! — *Seven*.

Count them. — *1, 2, 3, 5, 7*.

Count up to 10. — *1, 2, 3, 4, 5, 6, 7, 10, 12*.

[237] She couldn’t say the alphabet or do simple multiplication. When she attempted to write, extremely strong tremors appeared; she could not produce a single legible word with her right hand but managed a bit better with her left. She could read only with the utmost difficulty, and frequently misread the letters. With numbers it was even worse; she could not distinguish between 4 and 5. She recognized objects held before her. No symptoms of apraxia. She proved very suggestible. For instance, she was told when standing by the bed in her nightgown that she had a pretty silk dress on. “Yes, very pretty,” she said, stroking the nightgown with her hand and looking down at herself. Then she wanted to lie down in bed again. “But you can’t go to bed with your clothes on!” Silently she began unbuttoning her nightgown, then stopped suddenly: “But I’m not wearing a nightgown!”

[238] *June 6.* The patient’s condition was about the same, but she now knew her name was F., though she still gave “Ida” as her first name. She knew her age, but was otherwise totally disoriented.

[239] *June 7.*

How long have you been here? — *A long time*.

Twenty years? — *Yes, a very long time*.

You’ve only been here a week, haven’t you? — *Only a week?*

Where are you? — *In Munich. Must I always keep telling you?*

Where are you staying? — *In hospital. There are lots of sick people here, but I’m not sick.*

What’s the matter with these sick people? — *Headache*.

Who am I? — *The doctor*.

Have you seen me before? — *No*.

So today is the first time? — *No, yesterday*.

What day of the week is it? — *Sunday*. (Wrong answer.)

Month? — *The second*.

Year? — *I don’t know*.

1899? — *Yes*.

No, it’s 1892! — *Yes, of course*.

Or is it 1902? — *Yes, yes, 1902!* (In an emphatic tone of *voice*.)

No, it's 1900, of course it's 1900, I was all muddled up.

Weren't you in prison recently? — *No, I've never been in prison. A man with a beard hit me*.

Did that happen here? — *Yes*.

Have you any debts? — *No*.

Yes, you have! — *Well, I have a lot of money*.

Where from? — (No answer.)

How much? — *Quite a lot*.

How much, then? — *I don't know, I never counted it. It belongs to my daughter*.

Who was the father of your children? — *He died a long time ago*.

How old are you? — *Fifty*.

What year were you born? — *In May*.

What year were you born? — *I don't know*.

Is your daughter pregnant? (She was very near her time.) — *What's that mean?*

Is your daughter expecting a baby? — *No, it died*.

Have you only one daughter? — *Yes, only one*.

But you have two daughters! — *Yes*.

What is the name of your married daughter's husband? — *I don't know*.

[240] The patient talked quite well today, only stumbling over the more difficult words. She was slow at reading, but didn't make too many mistakes. Comprehension of what she read was much hindered by a high degree of distractibility. Only quite short sentences of the simplest order were understood and reproduced. Longer sentences were neither understood nor reproduced, though the patient did everything she was asked. She recited the alphabet faultlessly. Her counting still had gaps: 10, 11, 12, 13, —, 15, 16, 17, 18, —, 20.

[241] She still confused 4 and 5 when writing. Her writing was very much distorted by the tremor.

[242] On the following days her condition remained essentially the same.

[243] *June 9.* Better today, quick reaction, greeted me in a friendly manner. Orientation in space was correct, she knew her name was Godwina F. But had no idea when, how, or why she came here. Knew only of one daughter, Ida. Knew nothing of the existence of her brother, Carl F., nor of her arrest, her son-in-law, etc. No gross disturbances of sensibility ascertainable.

[244] *June 10.* Received a visit from her daughter Ida this morning. Still remembered it in the evening. Orientation maintained. She asked the wardress about the date.

[245] On being told that she was in detention, she exhibited strong affect, burst into tears, refused to believe it.

[246] *June 11.* Again a little better than yesterday. She was oriented as to place and time, but complained of bad headache. Lay quietly in bed, apparently very exhausted. Very distractible, and had to be prodded into answering. Her memory of events from June 6 back to several months before her arrest was grossly impaired. She had only the haziest ideas about her last stay in Zurich. She knew that she last stayed at a hotel run by a Mr. König, but could not remember the name of the hotel, despite my insistence. For the period immediately preceding her arrest, as also for the period of her detention, she had absolute amnesia. She could only remember that "a man hit her, not here, but somewhere else, probably in another hospital."

[247] Her memory starts again from about June 10. She still remembered her daughter's visit yesterday, but not her painful agitation on being informed that she was in detention. She remembered from June 9 or even earlier that she thought at first she was in Munich (where she had in fact been six months previously). Despite insistent examination, nothing more could be ascertained.

[248] Very nervous and frightened at the least thing. Easily fatigued, and several times wearily closed her eyes during the conversation.

[249] *June 12.* Fully oriented. Had all sorts of ideas about her situation. Thought she came here because she was ill with bad headache and

flickering before her eyes. Said she had been told the police brought her (she got this from the wardress), but that she knew absolutely nothing about it. Also that she had been in prison, but did not know how long, maybe a week. In prison she had been beaten because she said her money had been stolen. She thought she had put the money on the table and then it suddenly vanished.

[250] She also remembered her large debts and the charge of stealing. She was extremely nervous and easily tired, rather unclear in the head, and had to think a long time before answering.

[251] On the following days, no essential change.

[252] *June 18.* Not so frightened or so easily fatigued. Gave a coherent anamnesis, but it still contained a fair number of errors due to distractibility, particularly in the dates. Her memory was fairly clear up to the day of her arrest (May 31); from then on, uncertain. She had to think a long time before remembering the place where she was arrested; said it was in the morning (instead of 5 P.M.). She knew she had been up for a hearing, apparently only once, and said she'd been shut up in the cell for a week. She said the hearing took place on the first or second day of detention (June 2). (In reality it was immediately after her arrest, at 6 P.M., and on the following morning; she was also present at the examination of several witnesses.) She still vaguely remembered seeing her daughter there. (The daughter was arrested under the same charge.) She thought she had to sign something, but did not know what. On the second or third night "she was quite positive that she put the 10,000 marks which she'd been expecting on the table." The money was a great joy to her. Then it seemed as if the door suddenly opened and a black man came in, with bent head, who seized her by the shoulders with cold hands and pushed her into the pillows. Suddenly the thought came to her: "Christ, he's after my money!" She then came to herself from sheer fright, still feeling the cold hands on her shoulders; convinced herself that the door was shut, and looked round for her money on the table. It had vanished. She was in despair; she could not find her way about and no longer knew where she was. Next morning two men and two women came whom she did not know. One of the men seized her by the hair and

hit her. She screamed and “must have lost consciousness.” “It was just like being dead.” When she came to herself again, she was lying here (in the asylum) in bed. She thought she was in Munich, but the wardress told her it was Zurich.

[253] She now felt pretty well, except for the headache and for sleeping badly. Only at night she had bad dreams; for instance, of lying on kittens, or that swarms of cats were crawling over her.

[254] The patient still exhibited marked torpor and considerably reduced power of attention. Comprehension good. Retention very bad; she failed altogether to remember stories of any length. She was good at short, simple sums, but could not solve more complicated ones such as 3 × 17, 7 × 17, 35 ÷ 6, 112 + 73, as she always forgot one part of the calculation. Rapid blunting of attention owing to high fatigability.

[255] Precise sensibility tests showed poor discrimination between qualities of touch and temperature, particularly in the lower limbs. Perimetric examination showed normal field of vision. No analgesia.

[256] In the evening the patient was put for a short time into hypnotic somnambulism by means of a few passes and closing of the eyes. Under suggestion, she drank wine and vinegar from an empty glass. On being told that it was an apple, she bit a pen wiper and pronounced it very sour.

[257] Cautious questioning revealed that *the retrograde amnesia for the period from May 31 to the night of June 3 disappeared under hypnosis*. The patient related that she was arrested at 5 P.M. on the Bellevueplatz, where she was taking a walk with her daughter. The daughter was apprehended first, whereupon the patient, who was a few paces behind her, came up to see what was the matter. The hearing took place at 6 P.M. and continued on the following morning. (The details were confirmed by the daughter.) *The total amnesia for the period from the night of June 5 to June 10 resisted hypnosis*. No memory of this period could be awakened despite repeated attempts.

[258] The headache disappeared under suggestion. Deep sleep was suggested for the night, also amnesia for the whole content of the

hypnosis. The pains in the head were much better after she was wakened, and at night she slept uninterruptedly for eight hours.

[259] On the following days she was hypnotized fairly regularly, with good results. In each hypnosis she showed continuity of memory with the previous ones.

[260] *June 24.* The patient now spent the whole time out of bed, doing some kind of handiwork. Except for a certain dreaminess and distractibility, there were no more symptoms of note. *The retrograde partial amnesia and the total amnesia continued unaltered.* The patient proved very suggestible, so that posthypnotic suggestions were realized too.

[261] *June 27.* Today it was possible to penetrate the total amnesia by a trick.

[262] The patient was put to sleep in the usual way. She at once became cataleptic and profoundly analgesic.

[263] Are you hypnotized now? — *Yes.*

Are you asleep? — *Yes.*

But you can't be asleep, as you're talking to me! — *Yes, that's right, I'm not asleep.*

Look out, I'm now going to hypnotize you! (This procedure was repeated several times. The patient lay quite slack; the slight twitching of the arms that always occurs under hypnosis stopped.)

Are you asleep now? — (No answer.)

Are you asleep? — (No answer.)

You will be able to speak presently! (Passes were made over the mouth.)

Are you asleep? — (Softly and hesitatingly:) *Yes.*

How did you get here? — *I don't know.*

You are now in the detention cell, aren't you? — *Yes.*

And now the door is opening? — *Yes, and a policeman comes in, he's taking me to the asylum.*

Then how did you get here? — *In a cab*.

You are now in the cab. — *Yes, I'm awfully afraid in the cab, there's thunder and lightning and pouring rain. I'm always afraid of the big fat man who beats me*.

Now the cab stops, you are in the asylum. What time is it? — *Eight o'clock. I'm sitting in a little room, a gentleman with a beard comes in and says I needn't be afraid, nobody's going to hit me.… then two women come and then another, they put me to bed*.

[264] Here the memory broke off again. The patient's statements correspond exactly with reality. She was brought to the asylum in a cab, by a police sergeant, at 8 P.M., during a violent thunderstorm. On the way she clung frantically to the sergeant, saying in a terrified voice that she "was going to be beaten again." A doctor was present at her admission, also there were two senior wardresses, and the nurse came soon afterwards.

[265] During the next fortnight the patient's general condition underwent considerable improvement with occasional use of hypnosis. The scope of the amnesias remained unaltered.

[266] *June 21*. During the night the patient suddenly jumped out of bed, totally confused, in great terror, absolutely disoriented, and only after much persuasion could she be quieted down sufficiently to go back to bed. She stayed in bed this morning, trembling and starting violently when spoken to, expressing vague fears and complaining of dizziness and headache.

[267] Immediate inquiries revealed that yesterday, at a concert given in the asylum, she met a male patient who, before being admitted here, had put her in a very unpleasant situation indeed by blurting out the whole story of her brother, the habitual criminal, in the hotel where she stayed before her arrest. She had already complained, at the concert and afterwards, about the unpleasant impression the patient made upon her. After being ordered two hours' rest in bed, which had a very favourable effect, she was examined with the utmost care, and gave the following information:

[268] On going to bed yesterday evening she had dizziness and "noises" in the head. But she slept very well and now felt quite clear. She could not remember anything unpleasant that happened yesterday. When asked whether she remembered yesterday's concert, she suddenly got very red and her eyes filled with tears, but she said in an indifferent tone of voice that she remembered the concert quite well—which she proved by mentioning various details. Nothing unpleasant had happened at the concert. All indirect questions remained without result, only the direct question whether she had seen the patient M. reminded her of the incident. She now related the affair in an indifferent tone of voice, without showing any noticeable affects.

[269] *July 22*. Passed the night quietly. No deterioration.

[270] *In today's hypnosis the amnesia for yesterday's twilight state disappeared*. She was put back into the state of the previous night on its being suggested to her that she was frightened and did not know where she was. She then showed how she jumped out of bed. The wardress called out: "Miss F., be quiet and go back to bed." But she did not go back, tried to hide herself, and felt terribly frightened; then a fellow patient came to comfort and soothe her. (Details of her account could be objectively confirmed.)

[271] *July 24*. Still complained of headache and sleeping badly.

[272] *It was suddenly discovered that even without double hypnosis the patient had a hypnotic recollection of the twilight state from June 4 to June 10*. Her memory now goes back to the morning of June 5, of which she reproduced the scenes of the visits and the examination with a wealth of detail. A fair amount was also elicited from the days following the 5th, but this could not be verified for lack of precise information. As a post-hypnotic suggestion she was told to remember the episode from the twilight state. In place of the short sleep, the hypnosis was followed by hysterical somnambulism, in which the patient mistook me for her lover and addressed tender words to "Ferdinand." By means of a few passes and energetic suggestions for sleeping, the twilight state was terminated and then converted into simple sleep. Total amnesia after waking. The

post-hypnotic suggestion that she would remember her admission to the asylum was not realized.

[273] The patient was discharged on July 25 under police escort.

[274] On August 8, 1902, she wrote in a letter to an acquaintance in the asylum: “Ever since I’ve been here [abroad] I’ve felt unwell, when I wake up at night I don’t know where I am, and I get the feeling that I can’t think any more. I have to jump up and run about the room until I know where I am again.”

[275] The patient wrote that she was in a difficult situation because of money.

*

[276] This case has several interesting peculiarities to offer. It is undoubtedly a purely hysterical ailment.

[277] While in detention, the patient suffered from a delirious twilight state, which after a short pause passed into a stuporous stage characterized by the symptom of the “senseless answer,” strong disturbance of attention despite fairly good comprehension, high suggestibility, fatigability, disorientation, timidity, nervousness, absence of catatonic symptoms, and disturbances of sensibility.

[278] In his lecture on a “remarkable example of an hysterical twilight state,” Ganser,[3] in 1897, gave a cursory account of states which were mostly observed in prisoners in detention. The picture most of the patients present is one of hallucinatory confusion; many exhibit active fear, together with various disturbances of sensibility. Generally, after a few days, there is a striking change, sometimes an improvement, followed by amnesia for the attack. These states owe their characteristic features to the “symptom of the senseless answer,” which consists in the patients’ “inability to answer correctly the simplest questions put to them, although it was obvious from the kind of answers they gave that they had understood the meaning of the questions fairly well. Their answers revealed a positively astounding ignorance and a surprising lack of

knowledge which they definitely must have possessed or must still possess."

[279] An alternating state of consciousness with defects of memory, in conjunction with other hysterical symptoms, provides the diagnostic basis for an hysterical twilight state. Raecke[4] has made a thorough study of such cases, and particularly of the symptom of the senseless answer. The cases he published in his first work were not all of the same kind and were not, perhaps, altogether unexceptional; consequently they provoked sharp criticism from Nissl,[5] who accused Raecke of faulty diagnosis and asserted that "Ganser's symptom of irrelevant talk is first and foremost a special manifestation of catatonic negativism." The irrelevant talk of hebephrenics and catatonics is a very well-known phenomenon, and I do not believe an observer with any experience could mistake it for the "senseless answers" of hysterics. The most he could do would be to overlook a catatonia masked by hysteriform symptoms. When the inadequate answers are the direct manifestation of catatonia, they are clearly characterized as catatonic by the significant absence of affectivity and by associations which seize on irrelevant points in the question, thus differing essentially from the deliberately senseless answers of the hysteric. The irrelevant talk of hebephrenics is often due merely to lack of interest, to the "don't care" attitude typical of such patients, perhaps also to negativistic compulsion. The senseless answer, on the other hand, is sometimes a product of semi-intentional negation, which opposes the effort to give an adequate answer, and sometimes a product of a deep restriction of consciousness, which prevents conscious association of the elements needed for an adequate answer. As an accompanying phenomenon very typical of these latter cases, we would emphasize the stuporous behaviour of the majority of the patients. Raecke, in his second publication,[6] describes several such cases of stupor, having already established stuporous behaviour in three of the five cases mentioned in his first publication.

[280] Severe temporary loss of the intellectual faculties is a symptom not uncommonly met with in the field of hysteria. Here I would mention in passing the cases of alternating consciousness described by Azam,[7] Weir

Mitchell,[8] Schroeder van der Kolk,[9] MacNish,[10] etc. Some of the patients had, after a prodromal stage of sleep, lost all knowledge even of the simplest things. Weir Mitchell's case did not even know the meanings of words. Similar intellectual defects are also found in the moria states of young hysterics.

[281] The phenomenon we are discussing has, however, a very different clinical setting in our case, and assumes a special aspect when combined with other symptoms. If we take Ganser's syndrome to mean a passing state of altered consciousness, amnesically separated from the normal state, in conjunction with exaggerated, negativistic senselessness, then its inner affinity with Raecke's description of stupor in convicts is unmistakable. This stupor is often found in criminals, generally soon after their arrest, and may be regarded as a consequence of the excitements and hardships they have undergone. An hallucinatory prodromal stage, preceding the stupor, is also found in Ganser's syndrome with the same clinical symptoms and can dominate the situation for a longer or shorter period. Similarly, disturbances of sensibility are common to both. The question as to the extent of amnesia is very obscure; like most hysterical amnesias, it is difficult and sometimes impossible to circumscribe. Course and prognosis are equally uncertain. One can only say that in this matter the same is true as in traumatic neuroses, where the illness stands in reciprocal relationship to the injuriousness of the cause.

[282] Our case seems to me particularly suited to throw light on those aspects of the Ganser-Raecke picture which are still relatively unexplored because they are so difficult to observe, that is, on the still open question of amnesia and the psychological mechanism of the most characteristic symptoms.

[283] In our patient, whose anamnesis had nothing special to offer, the picture described by Raecke developed in singularly pure form under the obvious influence of detention. In the loneliness of solitary confinement she naturally became intensely preoccupied with the misfortune that had suddenly befallen her; moreover, she was worried about her daughter, who was in the last stages of pregnancy, and on top of that there was the

anxiety and agitation caused by the charge of theft (which later turned out to be false). All this led to the outbreak of a delirious state on the fourth night of her detention, with violent motor excitement. As chief content of the delirium we find a syndrome which “every prison psychosis can offer for a time.”[11] It consists of that well-known mixture of hallucinatory wish-fulfilment and delusions of being wronged. We must regard as such a symptom of detention the episode which began like a vivid dream with a wish-fulfilling illusion and ended in a state of fearful perplexity and lack of judgment, where nothing could be corrected despite the fact that she was more or less awake. She dreamt that she received the expected *10,000* marks and put them on the table; a black figure suddenly comes in and gives her a violent fright; she leaps up; the hallucinations vanish, leaving behind them the delusions of being robbed, poisoned, etc. In the course of the next day the wish-fulfilling delusion gained the upper hand: the patient thought she was in a luxurious hotel, was very rich, had millions. At the same time she showed marked deficiency of intellect, which the prison doctor who was called in took for *dementia paralytica*.

[284] This intensification of a wish-fulfilling delusion to a real delusion of grandeur may perhaps have been due to extreme restriction of the mental field of vision, since, as Wernicke points out,[12] delusions of grandeur may easily arise when there is a lack of orienting ideas and a predominance of egotistic thinking. Raecke noticed much the same thing in his cases.

[285] On being admitted to the asylum, the patient presented a picture of the most profound restriction of consciousness, with marked anxiety and perplexity. A little later this state passed into a quieter phase characterized by absolute lack of psychic content; her consciousness was a *tabula rasa*. Continuity of all memories seems to have been broken; she fancied she was in a hotel, but this was rather a matter of guesswork, a faint echo of her previous life, than a real misinterpretation of her surroundings in delirium. She had lost all knowledge of the simplest things, even of her own name, and, as though it occurred to her in a dream, gave her daughter’s name as her own. In striking contrast to this marked deficiency of intellect was her good comprehension. She understood requests and questions well; only in her answers, or rather in

her centrifugal psychic performance, was any disturbance evident. As might be expected, the power of attention was almost entirely absent, so that the whole psychic process was broken up into apparently disconnected elements. This picture was completed by her suggestibility; anything one told the patient or forced her to do supplied the only content in her mental void, and this behaviour was quite consistent with her behaviour under hypnosis.

[286] This stuporous state is so far removed from catatonic stupor that the latter has no bearing whatever on a differential diagnosis of our case.

[287] Despite this apparently absolute mental blank, we have a number of clues to support the hypothesis of a psychic process, though it is abnormal in not being illuminated by consciousness.

[288] When asked her Christian name, the patient replied, “Ida.” Ida was the name of the daughter who was arrested with her. Asked whether she knew anybody called Godwina F., she replied, “Yes, she is in Munich.” The patient herself was formerly in Munich. The idea that she was now in Munich, a faint continuity of memory with her earlier personality, obviously gave her the shadowy idea of her former real stay in Munich, and hence a recollection of her real name.

[289] Was she ever in Zurich? “Never, but I’ve stopped there with my son-in-law.” The son-in-law did, in fact, live in Zurich, and the name “Zurich” stirred up memories of the unpleasant experiences she had there, which were also mainly connected with her son-in-law. This double connection thrust the memory of the son-in-law to the forefront, while the obvious answer—that she had been in Zurich—was rejected. We shall see more of this curious mechanism which is so characteristic of hysterical ailments.

[290] Asked what was the matter with the patients in the asylum, she replied, “Headache.” This answer shows that she was unconsciously oriented to her surroundings, but that her supraliminal consciousness could only produce a distant association to the right idea.

[291] The psychology of the next answer is very similar. Asked whether she had recently been in prison, she replied, “No, I’ve never been in

prison. A man with a beard hit me." Here again the right answer cannot be given, or rather it is flatly denied, and an idea closely associated with it is produced instead. The reverse, too, sometimes happens—an affirmative answer is given as a result of suggestibility, but must be denied immediately afterwards because of her peculiar negativism. Thus, when asked whether it was 1902, she answered, "Yes, yes, 1902—no, it's 1900, of course it's 1900. I was all muddled."

[292] Her orientation was quite unmistakable, however, in the episode of the suggested silk dress. The suggestion that she was wearing a silk dress was realized at once, and lasted until she wanted to undress in order to go to bed. At that moment the unconscious orientation broke through; she stopped suddenly and said, "But I'm not wearing a nightgown!" She knew subconsciously that she was standing there in her nightgown and that she would be completely naked if she took it off. The feeling of shame was stronger than the suggestion and prevented her from undressing—not, however, with the right motivation, but because of a suggested association to the right idea.

[293] With the improvement beginning June 9, despite fairly good orientation as to time and place, there was a striking defect of memory for all unpleasant events in the recent past, including all persons who were in any way associated with unpleasant memories for the patient. She remembered only her daughter Ida, but had no knowledge of her other daughter and of the son-in-law she quarrelled with, or of her brother the criminal. Although on June 10 she showed continuity of memory with the previous day, she no longer remembered the information which she received with such lively affect, concerning her arrest and detention. So once again something unpleasant was repressed out of the sphere of consciousness.

[294] As can be seen from the patient's history, the scope of her consciousness gradually reconstituted itself, except for her defective memory of the whole period of the twilight state (which remained irreparable up till the end of observation). As already reported, elucidation of her summary memory from the moment of arrest to the outbreak of psychosis in the night of June 3 presented no difficulty at all.

Much greater obstacles stood in the way of hypnotic elucidation of the twilight state. However, I succeeded in the end, by making use of two tricks mentioned in the literature. The first was devised by Janet.[13] In order to put his well-known medium Lucie into a deeper sleep for a definite purpose, he would hypnotize Lucie II (that is, Lucie I, already hypnotized into somnambulism) by means of passes, just as if she were not yet hypnotized. By means of this procedure Janet discovered Lucie III, whose memory was like a large circle enclosing the two smaller circles of the memories of Lucie II and Lucie I; that is to say, it had at its disposal memories not accessible to either of them. As an intermediate state between Lucie II and Lucie III, Janet found a deep sleep in which Lucie was absolutely uninfluenceable.[14] The same thing was observed in our patient. The short sleeping state which followed the second dose of hypnotism, and from which it was rather difficult to get the patient to speak, probably corresponds to the intermediate state mentioned by Janet.

[295] The second trick I used was the method used by Forel in Naef’s famous case.[15] This consists in putting the patient each time into the appropriate situation, thereby giving him *points d’appui* round which the other associations aggregate like crystals.

[296] By means of these two procedures it was possible to demonstrate that our hypothesis of an unconscious but none the less certain orientation—even during the deepest twilight state—was correct. We therefore find the remarkable fact that the apparently severe disturbance of the psychic process in the Ganser-Raecke twilight state is merely a superficial one, affecting only the extent of consciousness, and that the unconscious mental activity is little affected, if at all.

[297] The psychological mechanism whereby such a disturbance comes about is nicely illustrated in the story of the little relapse which was observed in the asylum, when the patient had that unpleasant encounter at the concert. In the evening she complained of dizziness and noise in her ears, and that night she suddenly woke up, totally disoriented, confused, and frightened. The next day she had amnesia for the nocturnal interlude, and, when examined for its aetiology, displayed a systematic negativism that prevented her from saying what had really happened, although the

words were almost put into her mouth. During this recital, she exhibited no adequate affect, but her sudden blushing and the tears in her eyes showed that the sore spot had been touched.

[298] Here we have the primary phenomenon in the genesis of hysterical symptoms which Breuer and Freud have termed *hysterical conversion*.[16] According to them, every person has a certain threshold up to which he can tolerate "unabreacted" affects and allow them to pile up. Anything that exceeds that threshold leads—*cum grano salis*!—to hysteria. In the language of Breuer and Freud, our patient's threshold had been reached and exceeded as a result of her detention, and the unabreacted affect—the "excitement proceeding from the affective idea"—flowed off into abnormal channels and got "converted." Just how it will flow off is "determined" in most cases by chance or by the individual; that is to say, the line of least resistance is in one case the convulsion mechanism, in another sensibility, in a third the disturbance of consciousness, and so on. In our case, to judge from all the crucial points in the patient's history, the determining factor seems to have been the *idea of forgetting*. Her "not knowing" turns out to be partly an unconscious and partly a half-conscious *not wanting to know*. Raecke thinks that the not-knowing he found so remarkable in his patients may be due to fear, the fear of not knowing the simplest things, which, by auto-suggestion, leads to a real and effective not-knowing. This may often be true; but with our patient the semi-intentional repression of anything unpleasant from her consciousness was such a striking and dominant feature that Ganser's symptom seems to be altogether accessory. It may be regarded as a pathologically exaggerated consequence of the unconscious urge to forget, since her conscious mind drew back not only from feeling-toned ideas but from other zones of memory as well.

[299] As to the clinical status of our case, we must define it as the "hysterical stupor of the convict" in the sense used by Raecke This special form of hysterical illness—if we leave out of account the "prison complex" of hallucinations and delusions–may be described on the basis of the material at present available as a "prison psychosis," since, with few exceptions, the cases so far known have been observed only in prisoners.

[300] In conclusion, I would like to thank my chief, Professor Bleuler, for his kindness in referring this case to me.

V

ON SIMULATED INSANITY

A MEDICAL OPINION ON A CASE OF SIMULATED INSANITY

ON SIMULATED INSANITY[1]

[301] Several cases of simulation have recently been published by Bolte,[2] who in the course of his article remarks that the question of simulation presents fewer difficulties in practice than it does in theory. I would not like to go all the way with this statement. As a matter of fact, cases do occasionally come up for observation which are extremely confusing and create any amount of difficulty for the specialists who are asked to give a medical opinion. It is precisely on the practical side that the art of the diagnostician is sometimes taxed to the utmost. Generally speaking, simulation used to be suspected much more frequently and injudiciously than it is now, yet in spite of this the older literature abounds in cases on which the observers were unable to reach agreement. Today, through our knowledge of the various clinical pictures of dementia praecox and hysteria, we have advanced a step further, and have also gained rather more insight into the question of simulation, though this is not to say that we have acquired greater certainty in regard to doubtful cases. We possess no infallible method of unmasking the malingerer and are as dependent as ever on the subjective impression he makes on the observer. As Bolte rightly points out, it is always a risky business to publish these cases at all, for it requires considerable literary talent to lend an air of plausibility to subjective impressions. It is an unfortunate fact, as Fürstner says,[3] that the observer cannot convey to the reader all the detailed nuances of the picture—the changing facial expression, the attitude, verbal response, and so forth. Hence no author need be surprised if the reader doubts his cases of simulation or at least finds in them something to cavil at. In any conscientious appraisal of simulation there is so much to take into account and so much to investigate that, in reading a report that is the least bit summary, one is apt to regret the omission of this or that item which seems of importance.

[302] Modern diagnostic requirements are far higher than formerly, when, strange as it seems, it was often simply a question of whether the case fit into the purely theoretical scheme of the psychoses or not. The prolonged

controversy over the famous case of Reiner Stockhausen [pars. 346ff. below] is particularly instructive in this respect. Since then, the theory of hysteria has brought us so much that is new and important that we are obliged to reckon with many more factors today than we were twenty years ago. Indeed, it is a well-known fact that the majority of malingerers are mentally abnormal and consist in the main of degenerates of various descriptions. How frequently hysteria occurs in such individuals it is difficult to say, but judging by other types of mental degeneracy the percentage must be very high, assuming, of course, that one takes as hysterical all "psychogenic" symptoms. The question of an hysterical disposition is of great importance in diagnosing simulation. The lying of hysterics is proverbial, and in the domain of psychiatry hysteria furnishes perhaps the most cases of simulation. We have reason to suppose that for simulated insanity, too, some importance attaches to hysteria, considering that a fairly large number of hysterical psychoses occur among persons in detention and among convicts, who are naturally greatly interested in simulating. Here I would refer the reader to the numerous studies of twilight states recently made by Ganser.

[303] In judging a doubtful case of simulation, one must bear in mind that successful simulation is not a simple thing at all, but often makes the greatest demands in the matter of shamming, self-control, and psychic toughness. This cannot be achieved by mere lying, for the deception must be kept up with consistency and unshakable will power for weeks or even months on end. All this requires an extraordinary amount of energy, coupled with an art of shamming that would do credit to the most accomplished actor. Such cases are rare, but they nevertheless exist. There can be no doubt that among the ranks of the degenerate and criminally minded there are persons who possess a quite unusual amount of energy and self-control, which apparently extends even to the vasomotor processes.[4] Exceptions of this kind are certainly uncommon, for the criminal is characterized, as a rule, by an impulsive energy that tires quickly, rather than by endurance. The art of shamming, however, seems to be a gift that is widely disseminated among criminals. It is found chiefly in thieves and poisoners. The mendacity of thieves is well known; Krauss[5] says of them: "All common criminals lie, but their lies are clumsy and palpable. Only thieves lie skilfully and naturally. They lie unthinkingly, without a moment's

hesitation, as soon as they open their mouths. They no longer even know that they are lying. It has become so much second nature to them that they believe their own lies.” In agreement with this we find a preponderance of thieves among malingerers. Of the ten malingerers investigated by Fritsch, seven were up for larceny, and two of the other three had previous convictions for theft. Among 8,430 admissions to this asylum, I found eleven malingerers.[6] Of these, six had been investigated for offences against property (larceny, embezzlement, swindling), two had previous convictions for theft, and one had been investigated for attempted poisoning.

[304] Malingerers in this category of criminals therefore have a natural predisposition to deceive. If we discount the degree of intelligence and accidental factors which might assist simulation, then the one who plays his role best will be the one who lies most skilfully. The most confident of all liars are pathological swindlers, and the convincing thing about their lies is the fact that they believe them themselves, as they are no longer able to distinguish between truth and fiction. They differ from the actor in that the latter always knows when his role is at an end, whereas the former allow themselves to be hypnotized by the game they are playing, and keep it up with a curious intermingling of two mutually exclusive spheres of thought. Delbrück even speaks of a real double consciousness.[7] The more an actor enters into his role the more he loses himself in it, and the more his acting is accompanied by unconscious emotional movements of the body,[8] which is just why he “acts” so convincingly. The dramatic build-up of his role is certainly not a pure act of volition, but is chiefly dependent on a special disposition whose essential ingredient seems to be a certain amount of suggestibility. The greater this subjective suggestibility is, the more likely it is that the role which began as a mere game will falsify the reality, so captivating the subject as to replace his original personality. Pick[9] has given us a beautiful example of the way a daydream changes into a real twilight state. He tells the story of a young girl who flirted with the idea that she was an empress. She painted her role in ever more glowing colours, got so absorbed in it that in the end it turned into an hysterical twilight state with complete splitting of consciousness. The second case reported by Pick concerns a girl who dreamt herself into sexual situations and finally staged a rape on herself by lying naked on the floor and tying herself to the table and chairs. An interesting case of this kind is reported in a dissertation done

under Wernicke:[10] A girl fantasized that she was engaged, and she received letters and flowers from her fiancé which she had sent herself, with disguised handwriting. I observed a case of the same type in a young girl who played an elaborately contrived dream-role in her somnambulistic twilight states.[11] Such phenomena are not so very rare and can be observed in all gradations of intensity, from fanciful exaggerations to genuine twilight states. In all cases they begin with a feeling-toned idea which develops on the basis of suggestibility into an automatism. These experiences must be taken into account in a study of simulation. We should not forget that a large number of malingerers are hysterical[12] and therefore provide favourable soil for auto-suggestions and disturbances of consciousness.

[305] There is a Japanese proverb which says: "Thieving begins with lying." In the same way, congenital mendacity and an hysterical disposition are the beginning of simulation. The art of conscious shamming is a rare gift, so rare that it cannot be presumed in all malingerers, for sustained shamming requires an energy that exceeds the common measure both in quality and quantity. It ought not to be assumed so long as the commoner symptom of hysteria cannot be ruled out with certainty. We often find in hysteria all those mechanisms which make possible the most incredible toughness and a refinement of self-inflicted pain. When, for instance, a work-shy female hysteric can burn her feet in the most atrocious way with sulphuric acid, simply in order to get a free stay in a hospital, or another can kill off her entire dovecot so as to simulate haemoptysis with the blood, we may expect even more refined practices in individuals who are acting from feeling-toned motivations. In such cases we no longer have to reckon with the possibilities of normal psychology—which would be to credit them with the energy of a Mucius Scaevola[13]—but with subconscious mechanisms which far exceed the strength of the initial conscious impulse and, with the help of anaesthesias and other automatisms, bring about an auto-suggestion without further assistance from consciousness or even at its expense. The completely automatic nature of many hysterical symptoms explains their toughness and, in the case of histrionic performances, their perfection: since no reflective and deliberating conscious processes intervene, the subconscious complexes can reach full development. All doubtful cases of simulation should therefore be examined for possible hysterical symptoms, in the absence of suitable methods for investigating those disturbances of consciousness

which unfortunately elude observation all too easily and, in general, form one of the darkest chapters of psychiatry.

[306] If, then, we try to envisage the psychological mechanism of a twilight state on the basis described above, we shall not be surprised if the picture contains numerous elements which strike us as contrived and artificial, or even if certain symptoms are recognized as being wilfully produced. We should not, however, jump to the false conclusion that the other symptoms are being shammed as well. Similarly, technical tricks like the one recommended by Jacobi-Jenssen should be used with great caution, for if the subject takes over a symptom that has been suggested to him, this does not, in accordance with what we said above, decide anything for or against simulation. A confession of simulation at the end of the disturbance should be received with caution (especially when, as in one case, it followed a threat of a week's solitary confinement in darkness). Paradoxical as it may sound, certain experiences with hypnotized patients, who after an obvious hypnosis assert that they have not been hypnotized at all, make this caution necessary. On no account should one be satisfied in doubtful cases with a mere confession of simulation; a thorough catamnesis is needed for full elucidation, since only very rarely is objective insight into the inner state of the subject possible during the actual psychic disturbance. Despite confession there may easily be, in persons of a hysterical disposition, defects of memory that are unknown to the subject himself and can only be discovered by means of an accurate catamnesis.

[307] We spoke above of feeling-toned ideas that may have a releasing effect on an hysterical disposition. How severe the consequences of violent emotion may sometimes be can be seen from disturbances following accident and shock neuroses. Besides the long-term consequences of the affect, we also find at the moment of the affect itself peculiar disturbances which outlast it for a longer or shorter period. I refer to the emotional confusion known as "examination fright," "stage fright," or "emotional paralysis." The latter term stems from Baetz,[14] who, during an earthquake in Japan, noticed in himself a general paralysis of movement and feeling, despite completely unimpaired apperception. This accords with numerous other phenomena observed during and immediately after violent affects.[15] We all know the tragicomic confusion exhibited by men during fires, when

pillows and mattresses are carried downstairs and lamps and crockery thrown out of the window.

[308] In accordance with these observations on normal persons, we should expect something similar in degenerate subjects, though with abnormalities both quantitative and qualitative. Our knowledge in this respect is unfortunately very defective and the case material scanty. I have put together a number of observations on this subject, drawn from mental defectives, but for the time being they should be regarded as case histories.

1

[309] The first case concerns a mental defective who was sent to us for a medical opinion on a charge of rape. He had given perfectly reasonable answers at all the hearings, but, as the judge doubted whether the accused had the necessary power of discrimination to recognize the punishable nature of his action, a medical opinion was asked for. On admission the patient exhibited conspicuously stupid behaviour that made us suspect simulation. He spoke to nobody, walked up and down the room, his hands stuck impudently in his pockets, or stood apathetically in a corner and stared into space. When he was questioned, we had to repeat each question several times in a loud voice until the answer came. He stuttered, often did not answer at all but just gaped at the questioner. He was oriented as to time and place, but was unable to say why he was in the asylum. There were other striking peculiarities: when walking up and down the room he often made a sharp military turn, or would suddenly spin around himself where he stood (there was a catatonic in the room with him who made similar movements). After the fifth day his behaviour slowly began to change, he became freer in his movements, less rigid, demanded to know why he was here, since he was not mentally ill. Investigation now became possible, and we were immediately struck by the man’s extraordinary dull-wittedness; all his reactions were very slow, he had to think a long time before giving particulars, the story of his life was a jumble of fragments in chronological disorder, made up of unintelligible contradictions. He could no longer remember dates and names he had been quite familiar with before, but described them in a clumsy, roundabout fashion. For instance, he had once been dismissed from a firm of lithographers because he could not stand the smell of acid. He told the story as follows: “There was a thing standing open

where the thing was in, a sort of little dish, and then I felt sick," etc. On the following days he grew more alert, and finally was able to give a clear and coherent account of his affairs. He had insight for his initial stupidity and explained that it was due to the great fright he got when he was sent to the asylum, saying that he always felt that way when he came to a new place.

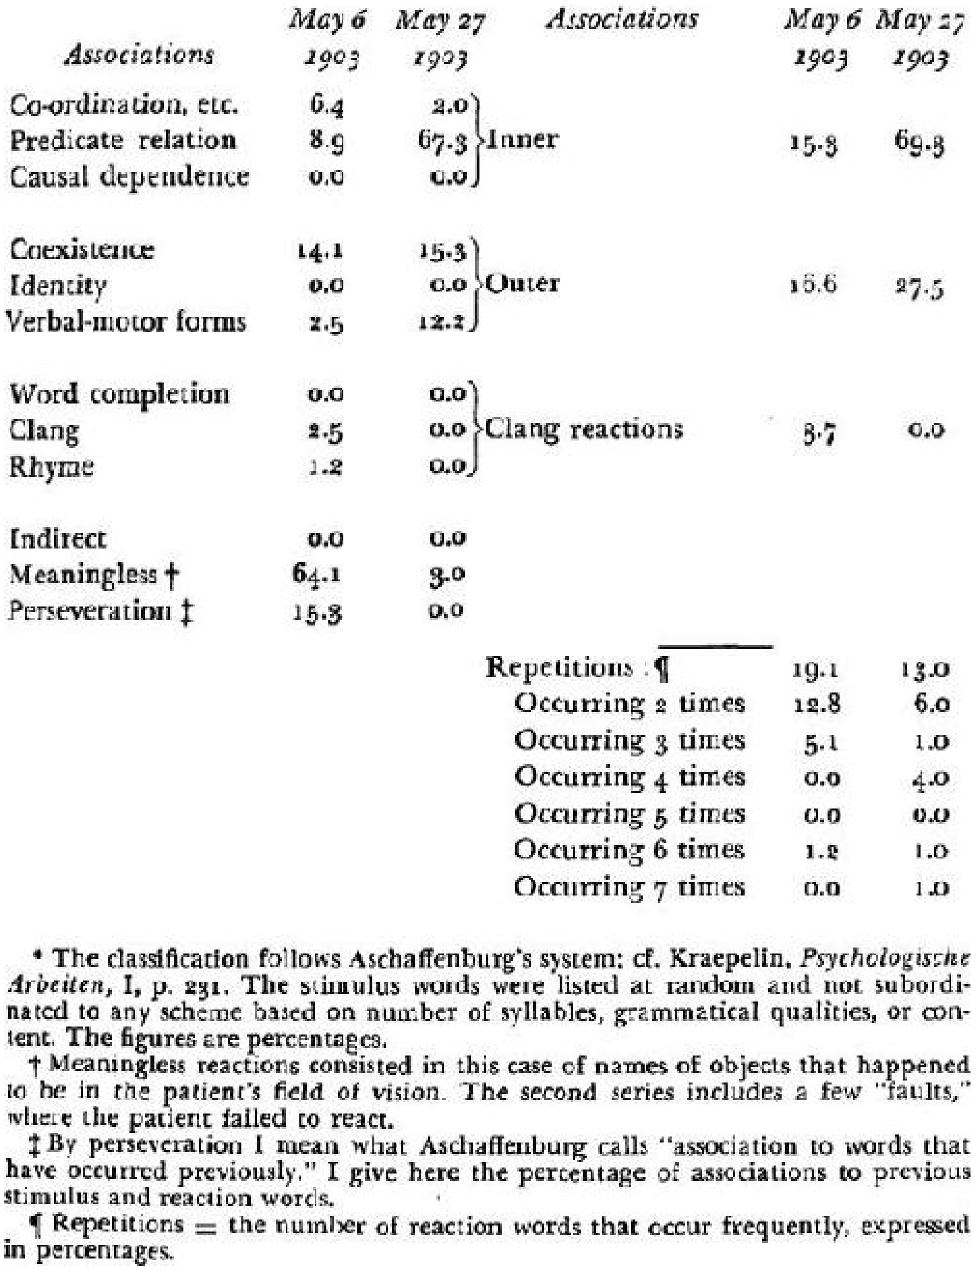
[310] Was the patient simulating? In my opinion not; he never tried to make capital out of this strange disturbance afterwards, although, with the stupid cunning of the mental defective, he sought every possible excuse for getting himself released. He seemed to regard this abnormal effect of emotion as a quite ordinary and regular thing. Moreover, it does not seem to me possible to simulate confusion and dull-wittedness, and particularly "examination fright," in so natural a way. Was his imitation of the catatonic intentional, unintentional, or merely accidental? I would prefer to reserve final judgment on this case.

2

[311] The second case again has to do with a feeble-minded individual, a 17-year-old boy who was sent to us for a medical opinion, also on a charge of rape. He behaved very apathetically at first, had an extraordinarily stupid expression on his face, and gave hesitant answers brought out with great difficulty. During his stay of several weeks in the asylum his condition gradually improved; he became brighter, gave quicker and clearer answers, and it was noticed that he associated with the warders and patients in a natural and unconstrained way much sooner than he did with the doctors. In order to obtain a more accurate picture of the disturbance I took two series of association tests, amounting to 324 in all, at an interval of three weeks. The first series was taken the day after admission. The tests produced the result shown in Table I.

[312] This list shows very clearly the change in the patient's mental state. The preponderance of meaningless reactions, clang reactions, and repetitions in the first series indicates a state of inhibited association which can best be described by the word "embarrassment."[16] With regard to the perseveration and its comparatively large preponderance in the first series, I would not venture to say anything where the material is so limited. This syndrome may be regarded as analogous to the one described in Case 1.

TABLE I *



Associations	May 6 1903	May 27 1903	Associations	May 6 1903	May 27 1903
Co-ordination, etc.	6.4	2.0	Inner	15.3	69.3

			Occurring 3 times	5.1	1.0
			Occurring 4 times	0.0	4.0
			Occurring 5 times	0.0	0.0
			Occurring 6 times	1.2	1.0
			Occurring 7 times	0.0	1.0

* The classification follows Aschaffenburg's system: cf. Kraepelin, *Psychologische Arbeiten*, I, p. 231. The stimulus words were listed at random and not subordinated to any scheme based on number of syllables, grammatical qualities, or content. The figures are percentages.

† Meaningless reactions consisted in this case of names of objects that happened to be in the patient's field of vision. The second series includes a few "faults," where the patient failed to react.

‡ By perseveration I mean what Aschaffenburg calls "association to words that have occurred previously." I give here the percentage of associations to previous stimulus and reaction words.

¶ Repetitions = the number of reaction words that occur frequently, expressed in percentages.

[313] The following two observations derive from investigations I am at present making with my colleague Dr. Riklin.

[314] (1) Embarrassment is a state in which the attention cannot be concentrated, as it is fixed elsewhere by a strongly accentuated idea. I tried to reproduce this state by distracting the attention at the moment of association. This was done as follows: the subject (who was naturally a practised one) was asked to fix his attention on the visual ideas that

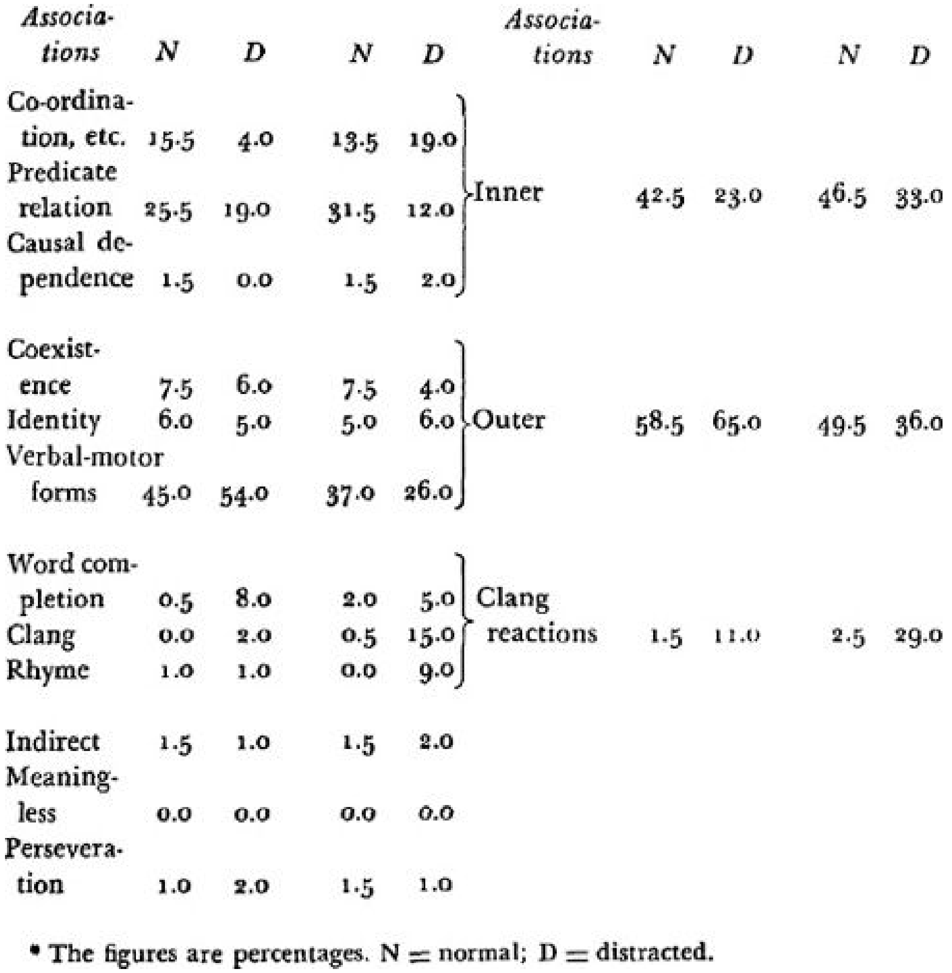
presented themselves as the stimulus word was called, but, as in the ordinary test, to react as quickly as possible. He was therefore in a state that corresponds more or less to embarrassment, since his attention was fixed and only a fraction of it was left over for the reaction simultaneously taking place. The two experiments, made with two different people, each consisted of 300 separate tests (Table II).

[315] (2) Similar results were obtained in experiments with outer distraction, where the subject associated while simultaneously making pencil strokes of a certain length in time to the beating of a metronome. A corresponding change is shown in Table III (page 170), based on 300 associations.

[316] In this experiment, practice naturally plays an important part, but the change in the associations is nevertheless very striking. Later on,[17] I shall give a detailed report on the experiments and their significance for psychopathology. I think these examples suffice to throw an explanatory light on the association disturbances of our mental defective.

[317] We see from these experiments that with inadequate investment of attention the quality of the associations shows a general deterioration; that is to say, there is a distinct tendency to produce outer and purely mechanical associations. A person who thinks in terms of such associations has very poor powers of comprehension and assimilation, and consequently comes very near to certain states of dementia. This may possibly be the reason for the feeble-mindedness heightened by emotionality observed in Case 2. The findings here throw some light on Case 1, which unfortunately was not subjected to detailed psychological investigation. In Case 2, simulation was quite out of the question, and yet the patient’s behaviour ran much the same course as that of the first. Is it not possible that when feebleminded and degenerate individuals are placed in an asylum the unwonted internment becomes associated with affects which are neutralized only gradually, in accordance with the poor adaptability of defectives? So far as it is possible to judge this matter at all, I should say it is not so much a question of mental defect as of a certain mental disposition, also found in other degenerate individuals, which puts abnormal obstacles in the way of an inner assimilation of affects and new impressions, and thus produces a state of continual perplexity and embarrassment.

TABLE II *



Associations	*N*	*D*	*N*	*D*	*Associations*	*N*	*D*	*N*	*D*

[318] How far this disposition to neutralize affects in a faulty or abnormal way coincides with hysteria is not easy to determine, but according to Freud's theory of hysteria the two are identical. Janet found that the influence of affects is seen most clearly in hysterical persons, and that it produces a state of dissociation in which the will, attention, ability to concentrate are paralyzed and all the higher psychic phenomena are impaired in the interests of the lower; that is, there is a displacement towards the automatic side, where everything that was formerly under the control of the will is now set free. Speaking of the effect of emotion on hysterical subjects, Janet says:

> Emotion has a decomposing action on the mind, reduces its synthesis and makes it, for the moment, wretched. Emotions, especially depressive ones such as fear, disorganize the mental syntheses; their action, so to speak, is analytic, as opposed to that of the will, of attention, of perception, which is synthetic.[18]

[319] In his latest work, Janet extends his conception of the influence of affects to all possible kinds of psychopathic inferiority; he says, as earlier:

> One of the marks of emotion is that it is accompanied by a decided lowering of the mental level. It brings about not only the loss of synthesis and the reduction to automatism which is so noticeable in the hysteric, but proportionately to its strength it gradually suppresses the higher phenomena and lowers tension to the level of the so-called inferior phenomena. Under the influence of emotion, mental synthesis, attention, the acquisition of new memories, are seen to disappear; with them diminish or disappear all the functions of reality, the feeling of and pleasure in reality, confidence and certitude. In place of these we observe automatic movements.…[19]

They have a particularly deleterious effect on the memory:

> But this dissociative power which belongs to emotion is never more clearly displayed than in its effect on the memory. This dissociation can act on memories as they are produced, and constitute continuous amnesia; it can also act suddenly on a group of memories already formed.[20]

This effect is of special importance for us, as it explains the disturbance of memory in cases of emotional confusion and also throws a remarkable light on the amnesias in Ganser's twilight states. In the Ganser syndrome which I analysed,[21] the most important feature was an anterograde amnesia which depended on affective elements. It was evident that the prolonged retrograde amnesia also present in this case covered all the unpleasant, powerfully affective events in the recent past. A relapse suffered by the patient while under observation was caused by a highly disagreeable affect. Phleps reports much the same thing in his above-mentioned study of the amnesia which, in his cases, was present for the causative affect (i.e., the Ljubljana earthquake).

[320] The picture presented by the two patients mentioned above was one of gross feeble-mindedness, which obviously set in acutely and was not caused by any demonstrable illness. Further observation showed that the degree of feeble-mindedness actually present was not nearly so great. In many so-called malingerers who sham a high degree of stupidity we find the same

outward behaviour, ranging from conscious, crassly nonsensical talk to the problematical borderline cases we have just been discussing. We find, however, in the twilight states described by Ganser, and recently by a number of other writers as well,[22] symptoms apparently indicating an almost impossibly high degree of feeble-mindedness, which in fact seems to be based on a purely functional deficiency that can be explained in terms of psychological motivations, as I have shown above. Ganser's "senseless answers" are of the same kind as those of the malingerer, only they arise from a twilight state that does not seem to me very far removed clinically from the cases of emotional stupidity reported earlier.[23] If we apply these remarks to the question of simulation, we can easily imagine that, in cases of emotional confusion following the excitements of arrest, interrogation, solitary confinement, etc.,[24] one person will hit on the idea of simulating insanity, while others will be inclined by the disposition I have described to lapse into a state of stupidity, in which, according to the mentality of the individual, conscious exaggeration, half-conscious play-acting, and hysterical automatisms will be fused in an impenetrable mixture, as in the picture of a traumatic neurosis, where the simulated and the hysterical are inseparably combined. I would even say that in my view it is but a step from simulation to Ganser's syndrome, and that Ganser's picture is simply a simulation that has slipped out of the conscious into the subconscious. That such a transposition is possible is proved by the cases of pathological swindling and pathological dreaminess. A contributory factor in all this is the abnormal influence of affects mentioned earlier. The literature on simulation leaves much to be desired in this respect, as very often in difficult cases the experts are only too delighted if they can succeed in unmasking one or the other symptom as simulated, and this leads to the false conclusion that everything else is "simulation" as well.

3

[321] Here I would like to report on a case[25] which is instructive from several points of view.

[322] J., born 1867, mill-hand. Heredity: father quick-tempered, mother's sister melancholic, committed suicide.

[323] Nothing special is known of the patient’s youth, except that his father early prophesied prison for him. At 16½ he ran away from home and began wandering, working in various textile-mills for about seven years. At 22 he married. The marriage was not happy, the fault being entirely his own. After two years he ran away from his wife, taking with him her savings, emigrated to America, where he lived an adventurous and roving life. Came back after some years to Germany and tramped through it on foot. Arrived in Switzerland, he made it up again with his wife, who soon afterwards filed a petition for divorce. He ran away from her a second time, embezzled a sum of money entrusted to him by a fellow worker, spent the lot, and was arrested and sentenced to six months’ hard labour (1892). After serving his sentence he resumed his roamings round Switzerland.

[324] In 1894 he was sentenced to a month’s imprisonment for theft. He is stated to have attempted suicide about this time (though not in connection with the punishment). After his release he took to the road again until 1896. From then on he worked uninterruptedly for four years in the same mill. In 1900 he married for the second time. This marriage, too, was unhappy. In 1901 he ran away from his wife, taking with him her savings to the value of 1200 francs. He went on a binge with it for a fortnight, then came back to his wife with 700 francs. Later (1902) he again took her money and ran away for good, committing two thefts when the money gave out. He was arrested soon afterwards and was sentenced to six months’ hard labour for the first theft. It was not until the spring of 1903 that he was recognized and arrested for committing the second theft. At the first hearing he gave his particulars correctly, but denied the charge, involved himself in contradictions, and finally gave quite incoherent and confused answers. In solitary confinement he became restless at night, threw his shoes under the bed, covered the window with a blanket “because somebody was always trying to get in.” The next day he refused food, saying it was poisoned. Gave no more answers, saw spiders on the wall. The second night, in a communal cell, he was restless, insisted that there was somebody under the bed. The third and fourth day he was apathetic, wouldn’t answer, ate only when he saw the others eating, maintained that he had killed his wife and that there was a murderer under the bed with a knife. The prison doctor testified that the patient gave the impression of being a catatonic.

[325] He was admitted on June 3, 1903, for a medical opinion.

[326] The patient seemed listless, apathetic, his face rigid and stupid-looking. He could be made to answer only with difficulty. Stated his name and address correctly, but appeared disoriented as to time and place. He gave five fingers held before him as four, ten as eight. Could not tell the time, named coins wrongly. He complied with requests correctly but carried them out in a senseless manner. When asked to lock the door he persistently tried to put the key in upside down. He opened a matchbox by breaking open the side. Strong suspicion of simulation. Was put in the observation room. Quiet at night, got up only once to move his bed, saying that the decoration on the ceiling would fall on top of him. Next day the same. At the examination he gave senseless answers and had to be pressed all the time. It was clear that he understood questions and requests quite well, but did his best to react to them in the most senseless way possible. Could not read or write. Took the pencil in his hand correctly, but held the book upside down, again opened the matchbox from the side, but lit a candle and put it out again correctly. He gave quite senseless names and values to coins.

[327] Physical examination showed brisk reflexes of forearm and patella. Sensibility to pain seemed generally reduced, almost non-existent in some areas, so that there was only a scarcely perceptible reaction to really deep needle-pricks. The right pupil was somewhat larger than the left; reaction normal. The face was markedly asymmetrical.

[328] This examination was carried out in a separate room on the same floor as the observation room in which the patient had been previously. When the examination was over we told him to find his way back to his room by himself. He went first in the opposite direction and rattled at a door he had not passed before, and was then told to go in the other direction. He now tried to open two more doors leading into rooms near the observation room. Finally he came to the right one, which was opened for him. He went in, but remained standing stiffly by the door. He was told to make his bed, but stood there without moving. His bed was in the corner facing him, clearly visible from where he stood. So we let him stand. He stood rigid on the same spot for an hour and a half, then suddenly turned pale, sweated profusely, asked the warder for some water, but fell unconscious to the floor before it arrived. After lying on the floor for ten minutes and recovering himself somewhat, he was put on his feet again, but rapidly went into another faint. He was then put to bed. He didn't respond to questions at all,

refused food. In the course of the afternoon he suddenly got up and threw himself against the door with considerable force, head foremost. When the warders tried to restrain him because of the danger of suicide, a hand-to-hand fight ensued, and it took several warders to subdue him. He was put in a straitjacket, whereupon he quickly calmed down. On the night of June 4 he was quiet, turned his bed round only once. At the morning visit he suddenly seized hold of the doctor and tried to pull him into bed, then seized the warder. Hyoscine injection. On the following days he again showed dull and stupid behaviour with occasional attacks on doctors and warders, which however never came to dangerous blows. He seldom said anything, and what he said was always stupid and nonsensical, uttered in an unemotional, toneless voice. He refused all food for the first three days, but on the fourth day he began eating again, then better every day. On June 7 he suddenly demanded to have a vein opened because he had too much blood. When this was refused he sank back into a dull brooding. In contradiction to his apathetic behaviour, however, he seemed to take an interest in his surroundings; on seeing a patient in the bed next to him offering violent resistance to nasal feeding, he suddenly called out that they should tie the man's feet together, then it would go better. On June 8 he was given a strong dose of faradism. Poor reaction. He was told that this would happen daily from now on. On the morning of June 9 he was suddenly clear, demanded a private interview at which he made the following statement:

[329] You know very well that there's not much the matter with me. When I was arrested I was so scared and upset thinking of my mother and sisters, they being so respectable, that I didn't know what to say, so I got the idea of making things look worse than they were. But I soon saw you weren't taken in, besides I felt such a fool playing the looney, also I got sick of always lying in bed. I'm sick of everything. I think all the time of killing myself.… I'm not crazy, yet I sometimes feel I'm not quite right in the head. I didn't do this to avoid going to jail, but for the sake of my family. I intended to go straight, and hadn't been in jail for nine years until last fall.

[330] When asked how he came to simulate insanity, he said: "I was sorry for my old mother and regretted what I'd done. I was so frightened and upset that I thought, well, I'll make out I'm worse than I am. When I got back to the cell after the hearing I was at my wit's end. I would have done away with myself if I'd had a knife." He did not seem to be very clear about the

purpose of the simulation, said he “just wanted to see what they would do with him.” He gave adequate motives for his actions under simulated insanity. One striking thing was the statement that despite his four-day fast he had felt no appetite. A thorough anamnesis was now undertaken, a point of special interest being the patient’s remark that he was always driven from place to place by an “inner unrest.” As soon as he settled in one place for a time, the vague urge for freedom came over him again and drove him away. Throughout his story he showed a fair amount of uncertainty with regard to exact particulars (years and dates, etc.), but his uncertainty was quite surprising when it came to judging the time of recent happenings. Although otherwise properly oriented as to time, he maintained that he had been in the asylum for a fortnight (instead of six days). By the evening of the same day he had become uncertain again, and now wavered between ten and twelve days. He recounted the details of his stay in the asylum unclearly, and he no longer remembered many little incidents, trivial in themselves, that took place during his simulation; he also got various things muddled up in time. He had only a vague memory of his admission and the examination that followed; he knew that he had been told to put a key in the lock but thought he had done it correctly. He also remembered the examination on the next day, and said that the room had been full of doctors, about seven or eight of them (in reality there were five). He could still remember the details of the examination, but only when helped. With regard to the scene that took place afterwards, he made a statement to the following effect:

[331] He remembered quite well how he came out from the examination; we had turned him loose and he lost his way in the big corridor. It seemed to him that in order to reach the examination room he had first gone up some steps. Then, when he found that he did not have to go down any steps, he thought we wanted to fool him and lead him to the wrong room. Therefore, when we eventually took him to the sick room, he thought it was not the right room, nor did he recognize it again, especially when he saw that all the beds were occupied. (But his bed was empty and clearly visible.) That was why he remained standing by the door, then he felt queer and fell over. Only when he was put to bed did he notice that there was a bed unoccupied, that it was his bed and that he was in the right room.

[332] He treated this intermezzo as if it were simply a misunderstanding, without the least suspicion that it was something pathological. The

dangerous ruthlessness with which he banged his head against the door he explained as a deliberate attempt at suicide.

[333] The next day, June 10, we got the patient to do simple additions based on Kraepelin's arithmetic tests. The average performance per minute was 28.1 additions, out of a total of 1,297 additions in 46 minutes. Increased practice produced an insignificant result: the difference between the average performance in the first and in the second halves amounted to only 1.5 in favour of the latter. So not only was the performance very poor, but the increased practice proved to be insufficient. In comparison with this relatively very easy work the number of errors was abnormally high: 11.2% of the additions were wrong; there were 1.5 errors per minute in the first half, 4.7 in the second half. These findings illustrate very well the rapid tiring of energy and attention despite the fact that there was no abnormal psychic fatigability. Optic perception was considerably reduced; the patient took a surprisingly long time to grasp the simple pictures in the Meggendorfer picture-book. His comprehension of things heard and read was likewise reduced. In reproducing a simple Aesop's fable, he left out important details and made up the rest. His retention, particularly for figures, was poor. As already indicated, his memory of events in the not so recent past was tolerably good, and he had retained a normal amount of school knowledge. No signs of mental defectiveness. No restriction of the field of vision. No other hysterical symptoms. Red-green blindness. Reflexes as at the first examination. No disturbances of sensibility other than general hypalgesia. About a week later (June 19) he was subjected to another thorough examination, having maintained correct behaviour in the meantime. No changes in his physical condition. Comprehension still not up to normal, but a decided improvement noticeable. No improvement in retention, but his work-curve showed a change for the better.

[334] For the sake of clarity I give the results of the first and second tests side by side:

TABLE IV

	June 10	*June 19*
Average performance per minute	28.1	32.4
Average per minute for first half	27.4	31.9
Average per minute for second half	28.9	32.9

Error in total number of additions	11.2%	4.0%
Errors per minute for first half	1.5	1.1
Errors per minute for second half	4.7	1.5

[335] The result of the second test shows an increase of 4.3 in the performance per minute as compared with the first series, and a very definite reduction in the number of errors. This result may be taken as confirming our clinical observations, in so far as a distinct improvement in the patient’s energy and attention did in fact occur in the course of a week. Unfortunately, he was not given an association test. On June 23 he made an ostentatious attempt at suicide by slowly sawing through the skin of his left wrist with a sharp stone. Afterwards he put up a childish resistance to being bandaged.

[336] The medical opinion stated that the patient must be assumed responsible for the theft, and therefore punishable, but only partially responsible for the offence of simulation.

[337] There can be no doubt that the patient really did simulate. We have to admit that the simulation was excellent, so good, in fact, that, though we never lost sight of the possibility of simulation, we sometimes seriously thought of dementia praecox or of one of the deeper hysterical twilight states mentioned by Ganser. The consistent masklike rigidity of the face, the dangerous nature of his suicide attempt (banging his head against the door), the real fainting-fit, the—to all appearances—deep hypalgesia, are facts which cannot easily be explained as mere simulation. For these reasons we soon discarded the idea of pure simulation on the supposition that, if it really was a case of simulation, there must be some pathological factor in the background which somehow lent a helping hand. Hence the sudden confession came as something of a surprise.

[338] To judge by the material reported above, the patient was a degenerate. His forgetfulness and lack of concentration point to some form of hysterical inferiority, as grosser cerebral lesions seem ruled out by the anamnesis. Although we have no other direct indications of hysteria, this assumption nevertheless appears the most probable. (Hypalgesia is a mark of degeneracy which is also found elsewhere, particularly in criminals.) As we have seen, the patient got confused at the hearings, and explained that this was due to his state of desperation at the time, i.e., to a strong affect. The question of the logical motivation in this case still remains very obscure,

and it looks as if he never came to a really clear decision to simulate. In his catamnesis he expressly emphasized and reiterated the strong affect he had experienced, and we have no grounds for not believing him in this point. It looks, rather, as if the affect played an important aetiological role. Although every feature of the resulting clinical picture is simulated (with the exception of the fainting-fit), almost every symptom is accompanied by phenomena that cannot be simulated. Lest I should lose my way in details, I shall confine myself solely to the fact, revealed by the catamnesis, that at least at times during his simulation the patient had a defective and faulty comprehension, as was borne out by the disturbance of attention noted on June 9. Accordingly, his memory of the critical period also proved strikingly vague. So, together with simulation, we find real and appreciable disturbances over the whole field of attention. These disturbances outlive the simulation and get very much better in the course of a week.

[339] Earlier writers maintain that simulation has a deleterious effect on the mental state.[26] Allowing for diagnostic errors, the impairment will probably be confined to a disturbance of attention resembling hypnosis; this may offer a plausible explanation of our case.[27] It should not be forgotten, however, that an alteration of this kind never occurs as a result of a mere decision: a certain predisposition is needed (what Forel would call a “dissociation”). And this is where, in my view, the decisive importance of affects comes in. As we have already explained at some length, affects have a dissociating (distracting) effect on consciousness, probably because they put a one-sided and excessive emphasis on a particular idea, so that too little attention is left over for investment in other conscious psychic activities. In this way all the more mechanical, more automatic processes are liberated and gradually attain to independence at the cost of consciousness. Here I would call attention to the beautiful experiments conducted by Binet[28] and Janet[29] on automatization in states of distractibility.

[340] On this foundation Janet based his conception of the influence of affects, which holds that automatisms are one and all fostered by distractibility (i.e., feebleness of attention) and, as Binet expresses it, thrive chiefly on “the psychic shadow side.” The assumption therefore is that certain ideas, which are present in consciousness at the same time as the affect but whose content need not be in any way related to it, become automatized. This assumption is amply confirmed by clinical experience,

and particularly by the anamnesis of hysterical tics. Our case, showing a state of semi-simulation, has as its essential symptom a strong and stable disturbance of attention such as occurs in a hypnotized person, whose attention is likewise fixed in a certain direction. Any interesting object can so attract our attention that we are “transfixed” by it. Hysterical subjects go even further—they have a tendency to identify themselves more and more with the object of interest, so that not, as in normal persons, a limited, but an unlimited number of associations is produced with all their subconscious ties. Owing to the peculiar nature of hysteria, these ties can be severed only with the greatest difficulty. From this point of view I see our patient as a malingerer whose malingering worked only too well, in the sense that it slipped into the subconscious.

[341] It would be desirable if more attention were paid to borderline cases of this kind. They might, perhaps, throw light on many things which at present are extremely difficult to explain. Here I am thinking of a case on which several medical opinions have already been given by different German clinics. It concerns an accomplished swindler and thief who, the moment he is arrested, sinks into a catatonia-like stupor for months at a stretch. A medical opinion was also given on this case in our asylum. The moment he was released, the patient suddenly awoke from his profound, stuporous imbecility and took a polite and ceremonious farewell.

[342] I have to thank my colleague Dr. Rüdin for the following case from the Heidelberg clinic, concerning an individual who had several previous convictions for theft and offences against decency. He had been epileptic for fourteen years. After his arrest for the second offence against decency in 1898, the patient could scarcely be made to answer at all, and a few days later became completely mutistic, remaining in a stuporous condition for seven months with unimpaired orientation. In 1901 he was caught *in flagrante* committing burglary with theft, became very excitable, then relapsed into his stuporous attitude for six weeks. In 1902 he was again arrested for theft, but this time he was very timid, silent, and gave only the briefest answers. Afterwards he became mutistic again, would not obey requests, but was otherwise quite orderly. A medical opinion was given on all three occasions and he was declared irresponsible on grounds of epileptic stupor.

[343] Leppmann[30] reports the following case of "simulation": Mentally defective murderer, who, after making a full confession while in detention, lapsed into a stuporous condition ("depressive melancholia"). After the "depression" disappeared, he simulated imbecility with loss of memory for the recent past. Sentenced to fifteen years' imprisonment. After sentence was pronounced, the patient immediately relapsed into an apprehensive stupor.

[344] Landgraf[31] reports a remarkable case of simulation in an habitual thief. In the second year of his ten-year prison sentence he became imbecilic, dumb, and kept his eyes closed. He spent eight years in this state, in the sick-ward, often not eating for weeks on end, usually sleepless, and playing at night with fruit-stones, buttons, etc. He put up a violent resistance to narcosis with chloroform. Afterwards he appeared paralysed for a fortnight, and was incontinent. On the expiry of his sentence he was sent home, imbecilic, blind, and dumb. Suddenly he left the house, committed a series of brilliant robberies. A fortnight later he was caught, and exhibited the same abnormal behaviour as before. Certified as a malingerer, he was sentenced to ten years' imprisonment. While in prison he was imbecilic, blind, deaf, and dumb for ten weeks, never once forgetting his role. Then he opened his eyes and began working, but remained deaf and dumb until his death.

[345] Marandon de Montyel[32] reports on the following case: A menstruating, psychopathic woman tried to drown her four-year-old child, was arrested, made a full confession, and gave financial distress as the reason for her deed. A week later she recanted, shammed amnesia for the deed and its motive, acted like an imbecile, did not know either her surroundings or her past (anterograde amnesia). On account of simultaneous depression she was certified irresponsible and interned in a lunatic asylum, whereupon her condition improved. Several months later she came up before the public prosecutor, manifested violent fright, and the next day relapsed into "simulation."

[346] The case of Reiner Stockhausen, on which monographs were written by Jacobi, Böcker, Hertz, and Richarz in 1855,[33] deserves mention. Stockhausen was a degenerate individual, many times convicted for theft and vagrancy. At one of the hearings he grew confused, gave strikingly

senseless answers (Ganser), mostly negative in character: “It’s all up, I must shoot myself, always in need of money, but there’s nothing left, everything sold, everything gone,” etc.[34] Later he was less informative, often irritable, muttering half-intelligible answers and repeating stereotyped phrases: “Haven’t got nothing more, everything’s sold, spent, gone on drink,” etc. He was extremely unclean in his habits, slept little and fitfully.

[347] Three of the medical opinions assumed simulation, one insanity. Thereupon he was sent to an asylum for a year for observation. At first he was very excitable and inaccessible, then he “laid aside his stiffness and reserve more and more. He acted like a peaceable, fairly sociable, reasonable human being.” But as soon as “the conversation turned to things which might be connected with the crime he was accused of, or as soon as his mental health or his emotional state was touched upon, he seemed to get violently indignant and at once began talking like a madman.” A fourth medical opinion assumed simulation because the symptoms observed in the patient “did not accord with either melancholy, insanity, craziness, lunacy, or idiocy.” He was sentenced to fifteen years’ imprisonment, but it made no impression on him. Two years later he was still being examined off and on by the experts, and each time they found the logical continuation of symptoms that had already been in existence for three years.

[348] Finally, I would like to mention a case published by Siemens[35] of a young day-labourer, who, falsely accused of murder, wept continuously while in detention, protested his innocence, then refused to answer any more, kept on lamenting his fate, would not eat, slept badly. When excited, he smashed things. Probably imbecilic (reading and writing very poor). On being admitted to the asylum he seemed very frightened, had to be questioned repeatedly before he would answer, said he was not ill but slept badly, refused food at first. Later he refused to answer at all, gazed at the doctors uncomprehendingly, but told the warder the story of his arrest. In spite of his apathetic behaviour he was provoked to laughter at the jokes of a maniac. Remained in this state for two months, until his release. Received the news of his release without moving a muscle. At home he was still taciturn for a time, indifferent, not working. Then he became normal again, complained about the wrong he had suffered, denied he was insane.

[349] To our way of thinking, these cases can hardly be regarded as simulation. The characteristic feature of these disturbances is their dependence on external events, mostly of a highly affective nature; this, together with their clinical behaviour, brings them closer to the psychogenic ("hysterical") ailments described by Ganser and Raecke, and also (particularly the last case) to the kind of stupidity I would describe as "emotional." Freud has offered convincing proof that the chief aetiological role in psychogenic disturbances is played by affects. It would therefore be worth while to pay more attention than we have done hitherto to repressed affects in criminals who exhibit doubtful states. We already have a number of pertinent observations; for instance, the intercurrent Ganser syndrome noted by Westphal[36] can be traced back to emotion, and a similar case is reported by Lücke.[37] The recurrence of a Ganser syndrome observed by me[38] conformed absolutely to the Freudian mechanism of repressed affect. One may therefore, with some justification, regard these peculiar states as due to the prolonged influence of affects, and in psychogenic disorders it is not surprising if all kinds of "faked" symptoms creep in, depending on the environment.

[350] It is impossible to discuss the question of simulation on the basis of the existing case material without making certain observations of a general nature.

[351] First, as regards the material, one can scarcely imagine any that is more unequal and more difficult to evaluate. In many cases the method of description is at fault, since the main stress is laid on the obvious symptoms, while the other symptoms—the hysterical ones especially—come off very badly. The investigation and "unmasking" of symptoms often consist in technical tricks, if not in old-fashioned cruelties like cold showers, etc. The standpoint of the earlier writers (which has even been passed on to some of the books now in vogue)—namely, that anything which does not fit into the known clinical pictures or into a dogmatic system of ideas is not a disease but simulation–is depressing and highly unscientific. Particularly damaging to description and investigation alike is a diagnostic optimism,[39] that accords very ill with the facts. From time to time we meet with cases of simulation which can lead the most experienced doctors by the nose for a long time. There was, for instance, Billod's patient,[40] who simulated nine

times with success; a case of Laurent's[41] simulated successfully for two years; and a case, "unmasked" on a second examination as a skilled malingerer, who had been declared incompetent on the authority of a very experienced doctor.[42] So we have every reason for caution.

[352] Secondly, there is another point worth mentioning: the concept of simulation is not understood by all the authors in the same way. Fürstner[43] mentions the following case of "simulation" by seventeen-year-old Sabina S., who, spurred on by reading the life of Katharina Emmerich,[44] staged an enormous swindle by passing herself off as a saint. She abstained apparently from all food, twice drove nails through her insteps to the soles of her feet, and performed all sorts of miracles which fooled the doctors and officials and created a great sensation. When examined by Fürstner, she induced true-to-life tonic and clonic spasms of the eye-muscles and in the face and throat muscles. In the asylum, of course, her mystic abstention from food, etc., turned out to be the sheerest swindle, very cleverly done. The purpose of the whole undertaking, apparently, was that she wanted to stay with a relative, who functioned as a priest.

[353] Such cases can hardly be described as simulation, for the means employed bear no relation to the ends but are merely symptoms of a known mental disorder of which history affords us hundreds of examples. When a criminal simulates insanity, that is a comparatively convenient and simple means of getting transferred to an asylum, from which he can escape more easily. Here the means are adapted to the ends. But when an hysterical girl tortures herself in order to appear interesting, both means and ends are the outcome of some morbid mental activity. An hysterical haemorrhage of the lung is something simulated, "faked," but that does not make the patient a simulant; she really is ill, only not ill with consumption. If the doctor calls her a simulant, he does so merely because he has not understood the symptom properly, i.e., has not recognized it as hysterical. When Sabina S. faked miracles she was not a simulant, if by this term we mean a person who is genuinely healthy and whose actions are intended to conceal his inner healthiness, whereas the abnormal actions of Sabina S. were precisely what revealed her inner morbidity. In the same way hysterics do not lie, even though what they say is not true in the objective sense. Wherever hysteria is involved, the term "simulation" should be used with caution in order to avoid misunderstandings.

[354] I would like to sum up the results of my work in the form of the following conclusions:

1. There are people in whom the after-effect of violent emotions shows itself in the form of a lasting confusion, which one could describe as “emotional stupidity.”

2. Affects, by acting specifically upon the attention, favour the appearance of psychic automatisms in the widest sense.

3. A certain number of cases of simulation are probably due to the after-effect of violent emotions and their automatization (or to auto-hypnosis) and must therefore be termed pathological.

4. Ganser’s complex in prisoners can probably be explained in the same way and must be regarded as an automatized symptom closely related to simulation.

[355] In conclusion, I would like to thank my chief, Professor Bleuler, for his kindness in allowing me to make use of the above material.

A MEDICAL OPINION ON A CASE OF SIMULATED INSANITY[1]

[356] Simulation of insanity is in general a rather rare phenomenon, being confined almost entirely to persons in detention and convicts. For the ordinary public the fear of the lunatic asylum is too great and this particular form of simulation too inconvenient for it to be worth their while to seek illicit advantages in this way. The sort of people who take to simulation have been found by experience to be composed for the most part of individuals who show unmistakable signs of mental and physical degeneracy. Experience shows, therefore, that simulation generally rests on a pathological foundation. This fact explains why the recognition of simulated insanity is one of the most difficult tasks of the diagnostic art. If the simulation is recognized and proved, it immediately raises the question of soundness or unsoundness of mind, and the answer to this is beset with all kinds of difficulties.

[357] Apart from cases of exaggeration of real or imaginary symptoms, we also find a number of peculiar mental states in degenerate subjects whose cause can be traced back to the powerful affects produced by the arrest, trial, and solitary confinement. Even among normal persons are many whose capacity to assimilate strong affects is much worse, and who are unduly depressed or irritated by unpleasant emotions and cannot recover their composure for a long time afterwards. In the domain of psychopathic inferiority, that broad and undefined zone separating the "healthy" from the "morbid," we find the various types of normality caricatured, and here the powerful affects manifested by normal individuals take on a character that is excessive and odd in every respect. The affective states are often abnormally prolonged or abnormally intense; they exert an influence on other parts of the psyche or on physical functions which are not directly touched by normal affects. Strange, sudden alterations of psychic behaviour may be produced in this way, and they are often so striking that they immediately make one think

of simulation. Such emotional-changes are observed among feebleminded persons especially, mostly in the form of extreme imbecility. The possibility that these states may occasionally be combined with conscious exaggeration makes the picture even more complicated. It is of some practical importance not only for the doctor, but also for the examining official, to be able to recognize psychological possibilities of this kind. The following case seems to me very instructive in this respect, as it concerns a prisoner who showed psychopathic inferiority with half-conscious simulation. The psychological and psychiatric side of this case has already been subjected to close study, and the findings were recently published in the *Journal für Psychologie und Neurologie*.[2] Here I am only putting the medical opinion on record. For the psychological discussion of this case I must refer the reader to the publication mentioned below.

[358] The case was referred to us by the District Attorney, Zurich.

Report

[359] We were asked to give an opinion on the mental state of I. G., of Rothrist, Canton Aargau, born March 24, 1867, millhand, and in particular to answer the following questions:

1. Is the respondent mentally ill?
2. If Dr. S. is correct in his suppositions, from what other mental illness might the respondent be suffering?
3. Since when is this condition presumed to have existed?

[360] The material on which our opinion is based consists of documents relating to the theft of a bicycle, of which the respondent is accused; documents of the criminal court, Schwyz, relating to theft in 1902; documents of the district court, Hinwil, relating to theft in 1894; documents of the district court, Baden, relating to embezzlement in 1892; a written statement by the respondent’s brother; the deposition of police constable S.; and observations made in the asylum.

1. *Previous History*

[361] The father of the respondent is stated to have been a respectable but rather quick-tempered man. The mother is alive and healthy. A brother of the father is alleged to be a religious crank. A sister of the mother committed suicide as a result of melancholia. Respondent has no children. His first wife had a still-birth.

[362] Nothing special is known of the respondent's youth, except that he was a naughty boy who was often told by his father that he would end up in prison. He attended school for eight years. At fifteen he entered a textile mill, where he worked for a year and a half. One day he ran away from the mill and found similar work in Turgi. He remained there for sixteen months, and states that he occasionally sent money home to his parents. Then he wandered off again and found another job in a textile mill in Wollishofen, where he remained about five months. After that he wandered about for "many weeks" and came to Linthal, worked for a year and a half, wandered off again, came to Ziegelbrücke, where he stayed about three years. At 22 he married. The marriage was not happy; after two years he ran away from his wife, taking with him her hard-earned savings, and emigrated to America, where he lived a roving and adventurous life, and eventually, after many wanderings, found work as a stoker on a European steamer which took him to Germany. From Bremen he wandered on foot all through Germany into Switzerland, came to Wald, worked there for six months, and was also reconciled with his wife. The reconciliation did not last long, however. After a time the wife filed for a divorce, which was granted. To this end she made use of the opportunity afforded her by the respondent's first offence. Apparently, in consequence of irregular employment, he had gone to Baden in Aargau, where he found work in a textile mill. He absconded on November 13, 1892, with 275 francs, which had been entrusted to him by his room-mate, as the respondent had at his disposal a lockable trunk. He travelled with his booty to Zurich, then to Mülhausen, Colmar, Strassburg, Belfort, Montbéliard, La Chaux-de-Fonds, Bern, and Glarus, where he was arrested on November 27, 1892, just as he was about to draw the dole. The money he embezzled had all been spent. He is also said to have had a previous conviction with ten days' imprisonment for fraud, some time

in 1892. He received six months' "correctional punishment" and was deprived of his civil rights for three years. After serving his sentence he roamed round Switzerland aimlessly, working here and there for short periods in various jobs. On March 15, he was sentenced to *one* month's imprisonment by the district court at Hinwil, for having pocketed a pair of pruning shears to the value of fr. 4.50. From the certificate of good conduct applied for on this occasion it appears that he had been apprehended "shortly before" in a "totally destitute condition" in Canton Glarus and had been sent back to his home parish; also that he first attempted suicide and showed himself very refractory in transit, so that he had to be locked up in the local jail, from which he broke out during the night and escaped.

[363] According to his own statement, he wandered or rather tramped round all the cantons of Switzerland until 1896, when he again found regular work in a textile mill in Schwanden. States that he remained there for four years and eight months, and married again in the autumn of 1900. The marriage was childless and not very happy.

[364] In the summer of 1901 he ran away on the Monday following a Sunday night debauch, taking with him a savings book belonging to his wife, showing funds amounting to 1200 francs, which he unlawfully drew at the bank in Glarus. Accordingly a description of him was circulated in the police gazette in Zurich. After a fortnight he came back again and gave his wife 700 francs. The rest he kept for himself. Eight weeks later he again ran away, ostensibly to look for work, taking with him another 400 francs. When, after a little while, he returned, he pretended to his wife that he had no more money left. But evidently he still had about 500 francs. After ten months he ran away again, always lodging in inns, and on September 15, 1902, stole a bicycle standing in front of a house, and on October 26 another bicycle from the corridor of a public-house in Siebnen, Canton Schwyz, valued at 200 francs, rode it to Lucerne, and was arrested on October 28, 1902, as he was about to sell it for 120 francs. He was sentenced to six months in the workhouse on November 22, 1902.

[365] Later it was learned that he sold the first bicycle to a mechanic in Glarus for 70 francs, or rather for a pair of field-glasses valued at 45 francs and the rest in cash.

[366] When questioned by the District Attorney on May 29, 1903, the respondent gave his particulars correctly, but denied the charge of theft and maintained that he had bought the bicycle from one Emil H. at the last church fête in Wädenswil. From then on his answers were unclear and inconsistent.

[367] Previous to this the respondent is stated not to have given any impression of abnormality. Only in solitary confinement did he become restless at night. He threw his shoes under the bed, covered the window with a blanket "because somebody was always trying to get in." The next morning he refused nourishment, saying the food was poisoned. Henceforward he spoke only when pressed, said there was a spider on the wall, that spiders were poisonous, and that this was a sign that he was being poisoned. On the night of May 31 he slept in a cell for four persons. He was restless at night, repeatedly asserting that there was someone under the bed. On June 2 his behaviour was still the same; he was apathetic, did not speak to the other prisoners, but ate when he saw the others eating. The District Medical Officer testified that the respondent's remarks ("they wanted to do him in because he had killed his wife," "he had seen a murderer under the bed with a knife," etc.) and his general behaviour gave the impression of a catatonic state.

2. *Observations Made in the Asylum*

[368] On his admission on June 3, 1903, the respondent sat there listlessly and could only with difficulty be made to answer. The expression of the face was dull and masklike. He gave his name and address correctly, knew he was in Zurich, but otherwise did not appear to be oriented as to time and place, and could not state the year he was born. He persistently gave 5 fingers held before him as 4, 10 as 8. He could not tell the time, said 5:30 for 5:50, 3:30 for 7:30, and when shown 3:30 said "also 3:30." He recognized only 5-franc pieces; 1-franc pieces he called 20 cents. On being given a key and asked to lock the door, he put the key in upside

down. He tried to open a matchbox sideways. He was then put to bed. During the night he was quiet, but moved his bed once, remarking that the plaster rose on the ceiling would fall on top of him.

[369] At the examination next morning he gave scanty answers, had to be continually pressed. He seemed unclear about time and place, said he was in a hospital in Zurich. He evidently understood all the questions quite well but gave senseless answers, all very curt and confined to the fewest possible words.

[370] Examples:

What is the name of this hospital? — *Zurich Hospital*.

What sort of people are in your room? — *Sick people*.

What is the matter with them? — *They can't walk*.

Aren't they wrong in the head? — *No, in the legs*.

How long have you been here? — *Two days*.

What day is it? — *Saturday*.

What day did you arrive? — *Wednesday*.

What day is it, then? — *Saturday*. (It was Thursday.)

What day is it? — *Sunday*.

What holiday was it last Sunday? (Whitsun.) — *Singing-festival in Zurich. I heard singing*.

Where were you last Sunday? — *In Zurich*.

What did you do? — *Nothing*.

Where do you live? — (No answer.)

Glarus? Wädenswil? — *Glarus*.

Where were you before you came here? — *Zurich*.

What did you do in Zurich? Did you go anywhere? — *Wandered around*.

[371] Respondent gave no more answers, despite energetic pressing. He was then asked to do various things, and it was noted that he understood the requests correctly, as previously the questions, but carried them out in a deliberately senseless manner.

[372] He was asked to write the word “Rothrist.” He at once took the pen in his hand and made a zigzag line.

[373] He was asked to read. He held the book upside down, tried to read from right to left. Called the letter O a “ring,” a 9 (inverted) “5”, a 1 a “line,” a 6 (inverted) “3”, a 4 (inverted) “2”, a 3 (inverted) no answer, a 2 (inverted) “2”, a 3 (inverted) “5”.

[374] Said spontaneously that he “couldn’t read it.”

[375] He was told to hold the book properly. He turned over the pages. The book was then placed before him. Question: What’s that? Reply: “What are you? Why are you here?” He could not be made to read.

[376] He was asked to lock the door with a key. He turned the key to the right to lock, to the left to open, both times with a show of strength. (N.B.: Lock opens to the right.)

[377] He was asked to open a matchbox. First he tried, as yesterday, to break it open from the side, but on being encouraged opened it properly, struck a match, also lighted a candle and put it out, both correctly.

[378] He was asked to open the blade of a pocket-knife: opened the corkscrew.

[379] He was asked to open a spectacles case and put on the spectacles. Spontaneous remark: “I don’t want any. They aren’t spectacles.” Turned the case over in his fingers, then opened it correctly when shown how to. Tried to put the spectacles on upside down.

[380] He was given a purse, with the question: What is that? “A little box.” What’s in it? “Cigars.” Tried to open it by pulling off the clasp.

[381] Some money (fr. 3.40) was put in front of him with the question: How much is that? “5 francs.”

[382] He was shown a gold piece (fr. 20) and asked: How much is that worth? “Nothing.”

[383] Physical examination showed brisk forearm and patellar reflexes.

[384] Sensibility to pain seemed to be generally reduced, in places almost non-existent, e.g., on the right forearm. Pupils reacted to pain; right pupil

somewhat larger than the left; both showed normal reaction. Face rather asymmetrical, the left eyebrow standing higher than the right. Badly swollen veins on the left leg. On the left side of the chest, over the second and third ribs, there was a scar 5½ cm. long and almost 3 cm. broad (caused by the alleged attempt at suicide).

[385] This examination was carried out in a separate room on the same floor as the observation room where the respondent had been since the previous evening. When the examination was over he was told to find his way back to his room by himself. He went first in the opposite direction and rattled at a door he had not passed before, and was then told to go in the other direction. He now tried to open two more doors leading into rooms near the observation room. Finally he came to the right one, which was opened for him. He went in, but remained standing by the door. He was told to make his bed, but stood there rigid, without moving. His bed was in the corner facing him, clearly visible from where he stood. We let him stand. He stood for 1½ hours on the same spot, turned pale, sweated profusely, asked the warder for some water, and suddenly toppled over before it arrived, slipping to the floor full-length by the stove. His face was pale purple and covered with sweat. He said nothing and did not react when spoken to, although he was conscious. After ten minutes he was put on his feet again, but hardly was he upright than he turned pale, his pulse very weak, soft, rather rapid. He was then put to bed, where he lay quiet and silent.

[386] Towards four o’clock in the afternoon he suddenly got up, went to the door and banged it violently with his head, then took a run and threw himself head foremost against the door with considerable force. (According to the head warder, there was such a racket that he thought “everything was falling to bits” in the observation room.) When they tried to restrain him he struggled so much that he had to be straitjacketed, whereupon he calmed down at once.

[387] On the night of June 4 he was quiet, turned his bed round only once, and then didn’t want to go back again. At the morning visit he suddenly seized hold of the doctor and tried to pull him into bed, then seized the warder and fought with him. He was given a narcotic by injection. On the

following days he exhibited the same dull, apathetic behaviour with occasional attacks on doctors and warders, though the attacks were confined to wrestling and never came to blows. He seldom said anything, and what he said was always stupid and nonsensical, and was uttered in an unemotional, toneless voice. He ate nothing for the first three days. On the fourth day he began to eat a little, then better every day. On June 7 he suddenly announced to the doctor that he had too much blood, and would they please open a vein—a request which was naturally not granted. It was also observed that in contradiction to his apparent apathy he took a lively interest in what was going on around; for instance he suddenly called out that they ought to tie up the feet of a patient who was offering violent resistance to nasal feeding, then it would go better.

[388] On June 8 he was given a strong dose of faradism, and was told that henceforth this would happen daily and would do a great deal to improve his condition, particularly his speech.

[389] On the morning of June 9 he was suddenly clear, demanded an interview with the director. He was taken to a separate room, where he delivered the following oration:

[390] "You know very well that there's not much the matter with me. When I was arrested I was so scared and upset thinking of my mother and sisters, they being so respectable, that I didn't know what to say, so I got the idea of making things look worse than they were. But I soon saw you weren't taken in, besides I felt such a fool playing the looney, also I got sick of always lying in bed. I'm sick of everything. I thought of killing myself. This week I asked to be bled and I planned to fight against being bandaged and so make the blood run. I'm not crazy, yet I sometimes feel I'm not quite right in the head. I didn't do this to avoid going to jail, but for the sake of my family.… I hadn't been in jail for nine years until last fall." (Wept.)

[391] When asked how he came to simulate insanity, he said: "I was sorry for my old mother and regretted what I'd done. I was so frightened and upset that I thought, well, I'll make out I'm worse than I am. When I got back to the cell after the hearing I was at my wits' end. I'd have jumped out of the window but for the bars. I thought I can't bring any more

disgrace on my mother and sisters. I'd have had a nice life if only I could have gone straight. I've always gone on the booze instead of working. My wife always told me I was wrong in the head—naturally, if your head's full of booze." He went on to say that he hadn't really known what would happen to him if he simulated, he just wanted to see what we would do. Other people had simulated and got away with it. He didn't know he would be taken to Burghölzli, he thought it would be the cantonal hospital.

[392] In this way he arrived at the idea of pretending to be mad. He hadn't eaten anything because he thought he would starve himself. (Another time he said he had lost his appetite.) He had been in despair and he still was; for all he cared we could open a vein today, the only reason why he had not killed himself before was that he did not want to bring more disgrace on his mother by committing suicide.

[393] He said he feigned fear of poisoning because it gave him an excuse for not eating. He simulated hallucinations because he knew that mad people often saw such things. When he was moved to a communal cell he was obliged to start eating as soon as he saw the others eating. During this recital the respondent repeatedly burst into tears and was obviously in a very penitent mood.

[394] On this and the following day (June 9–10) he was subjected to a thorough examination.

[395] Pupillary, patellar, and other reflexes showed no change. When tested for sensibility to pain the respondent definitely reacted, but it was clear that sensibility in general was considerably reduced in a uniform way over the entire surface of the body (hypalgesia). The visual field showed no restriction, but he was found to have typical red-green blindness. Apperception was considerably reduced, so that simple pictures were perceived very slowly and faultily. If he was shown a picture long enough, he understood it and could describe it correctly. When Aesop's fable of the ass in the lion's skin was read out to him, he understood the meaning but reproduced the story very inaccurately:

[396] An ass found a lion’s skin with a dead lion inside it. [This passage was a spontaneous addition of the respondent’s.] Then he took the skin and wrapped himself in it. He ran round roaring like a lion. Then the other animals tore him to pieces. The meaning is: Do not make yourself bigger than you are.

[397] His retention was likewise reduced, and this was particularly apparent in reckoning, as he easily forgot one or the other component of a simple sum. For instance, he could not calculate 147 + 178; even simpler sums were difficult for him, e.g., “15 + 17 = 42–yes, 42, no, 37.” He reckoned as follows: “15 + 15 = 30 + 7 = 37–no, 32.” Division was the worst; he could not solve 92 ÷ 8. Apart from poor aptitude for arithmetic, the fault lay chiefly with his reduced retention, i.e., a so-called bad memory.

[398] Otherwise he showed medium intelligence and a knowledge that was sufficient and appropriate to his circumstances.

[399] After this he composed an autobiography, running to five and a-half pages, in which he accepted the chief blame for his unsuccessful life and also for the unhappy outcome of his two marriages. In the same remorseful and contrite tone he gave an oral account of his life-history, emphasizing again and again that he alone was to blame for his criminal career, that he had drunk foolishly and neglected his work, that an inner unrest always drove him on his way and prevented him from settling down with his wife; he had never been able to “submit to the yoke.” Every so often he had to run away, driven by a vague urge for freedom.

[400] The story of his life was correct so far as it could be checked objectively. He was at fault only in the dates. He also told the story of his various thefts faithfully and without cover-up. He was surprisingly uncertain, however, with regard to the temporal location of recent happenings. He was unsure whether he had been three or four days in Selnau; on the morning of June 9 he was definite that he had been a fortnight in the asylum; later, towards afternoon, he thought it was certainly twelve days at least, and in the evening he hovered between ten and twelve days. Otherwise he was well oriented as to time. He recounted the details of his present stay in a confused manner, and he no

longer remembered many little incidents that took place during his simulation; he also got various things muddled up in time. He had only a vague memory of his admission and the examination that followed; he knew that he had been told to put a key in the lock but thought he had done it correctly. He remembered also the examination on the next day, and said that the room had been full of doctors, about seven or eight of them (in reality there were five). He could still remember the details of the examination, but only when helped. With regard to the scene that took place afterwards, he made a statement to the following effect:

[401] He knew quite well how he came out after the examination, we turned him loose and he lost his way in the big corridor. It seemed to him that in order to reach the examination room he had first gone up some steps. Then, when he found he did not have to go down any steps, he thought we wanted to fool him and lead him to the wrong room. Therefore, when we took him to the sick room, he thought it was not the right room, nor did he recognize it again, especially when he saw that all the beds were occupied. That was why he remained standing by the door. We let him stand there, and then he felt queer and fell over. Only when he was put to bed did he notice that there was a bed unoccupied, that it was his bed and that he was in the right room.

[402] The fact that he banged his head against the door so forcefully was, he explained, due to his desperation; he was in such a state that he didn’t care if he bashed his head in.

[403] (Respondent would not admit the suicide attempt reported in the documents. He stated that he had merely been monkeying about with a revolver, that it had gone off, and that he had no intention of committing suicide.)

[404] In order to obtain a more accurate picture of his condition at this time (June 10), we took what is known as his “work-curve.” We put him to adding up single figures for 46 minutes and then plotted the results (performance and error) in a curve.[3] The striking thing is the low level of performance per minute despite increasing practice, and the large, rapidly increasing number of errors. This behaviour was not the result of fatigue; it reflected a state of peculiar psychic debility and uncertainty.

[405] On the following days the respondent was left to his own devices. He passed the time in reading and playing cards, and complained off and on of vague ailments (“weak back,” etc.), grumbled about the warders and the asylum, saying that there was nothing whatever the matter with half the so-called patients here, etc.

[406] On June 19 he was subjected to another thorough examination.

[407] His physical condition showed no change.

[408] In his comprehension there was a distinct improvement, for although his perception was still uncertain and not quick enough, it was quicker and more accurate than before.

[409] No change could be demonstrated in his retention. Memory and calculation were just as uncertain as on June 9.

[410] On the other hand, the work-curve (taken on June 17) showed a distinct improvement. Not only was the average performance higher, there was also a considerable drop in the number of errors.

[411] Respondent now exhibited a continual mood of mild depression and often asked when he could go away.

[412] On June 23 he suddenly made an attempt at suicide by slowly sawing through the skin of his left wrist with a sharp stone, near the artery. On beginning to bleed he asked the warder for a knife, because he hadn’t “finished it off properly,” whereupon, of course, the attempt was discovered. At first he resisted when we tried to stitch and bandage the wound, but gave way at once when we threatened to have him held down by four warders.

3. *Opinion*

[413] The following points are clear from the material set forth under sections 1 and 2:

[414] Respondent has always inclined to lead a work-shy, vagrant existence. He never remained anywhere for long, was continually moving about and changing his job; he could not endure the settled life of marriage, quarrelled with his wife, embezzled her money, and squandered

it. If opportunity were favourable, he several times resorted to stealing. His characteristic instability was, in his opinion, due to an inner unrest which drove him forth again and again, even from jobs that might have suited him. He himself was aware of this peculiarity, and realized also that he had only himself to blame for his unfortunate career.

[415] Investigation shows that even apart from this peculiarity the respondent is not quite normal. He exhibits a number of deviations from the norm which, if not exactly pathological, must nevertheless be described as signs of degeneracy; for instance, general reduction of sensibility to pain (hypalgesia), red-green blindness (Daltonism), reduced attention, poor comprehension of things seen and heard, characterized by retardation and lack of accuracy.

[416] This abnormal condition comes nearer to congenital degeneracy than to any known mental illness. Owing to our meagre knowledge of the family circumstances no strong hereditary influences could be proved, but they may nevertheless exist.

[417] One can, if necessary, distinguish certain groups among hereditarily tainted persons which correspond to definite clinical pictures, according to the way the symptoms are constellated. The respondent comes closest to hysteria, since his chief symptoms—instability of character and forgetfulness—play a particularly prominent role in hysteria. Red-green blindness, dulling of the senses in general, are symptoms that are found in various forms of degeneracy (or “psychopathic inferiority”). His easy emotional excitability, his inquisitive interest in the asylum’s affairs, and his rash judgments, though they cannot with certainty be described as hysterical, nevertheless give that impression. On the other hand, the attempt at suicide, which stopped just at the point where it began to be dangerous, has a definitely hysterical character. (This is not to say that a depression cannot sometimes reach such a pitch that the attempt has a more than merely theatrical outcome.)

[418] In view of the fact that the respondent comes of an otherwise reputable family and is not just a moral degenerate, but was prevented from leading a steady and useful life mainly on account of his abnormal psychic disposition, we must assume that the reasons he gave for

simulation, particularly the powerful feeling of remorse, were in fact sufficient, although the psychology of it is not altogether clear. Indeed, it is remarkable how vague he was in this connection, for he had no very clear idea of what he really wanted to gain by simulation, and of what would happen to him if he simulated. It is probable that the thought uppermost in his mind was that his offence would be forgiven him; but, judging by what he told us, he had at the time absolutely no conception of the consequences of his actions. It looks very much as if he were following an inexplicable urge to extricate himself from his simulation rather than a clear train of thought.

[419] With regard to the outward appearance of his condition at that time, it must be emphasized that apart from a number of minor inconsistencies and improbabilities which always kept us on the watch for simulation, the respondent acted the part of a madman extremely well on the whole —so well, in fact, that there could be no mistaking a distinct affinity with certain hysterical twilight states on the one hand and with certain forms of dementia praecox (tension neurosis) on the other. The dull facial expression, the ruthlessness with which he banged his head against the door, his real fainting-fit, all these are facts which it would be difficult to explain as pure simulation. So even at this stage we had the impression that, if simulation were present at all, there must still be some pathological factor in the background which enabled the respondent to play his strenuous role. Further observation fully confirmed this conjecture. According to his own subsequent confession, it was an intentionally simulated insanity, but, without his either knowing it or willing it, it succeeded so well that it almost turned into real insanity—that is to say, it began to take on pathological features, because the meticulous imitation of a semi-imbecilic state had an effect on the normal activity of the mind, and this showed itself in various symptoms which could no longer be simulated. What the respondent said about the scene in the observation room is proof of this. His bad memory, which moreover was particularly defective for the whole period of simulation, cannot be held responsible for the above report of the incident, since it was a quite positive memory of a falsification of perception which cannot be regarded as normal and which sufficiently explains the oddity of the

situation at the time. We see from this that the respondent already had a pathologically indistinct and definitely falsified perception of his environment. Further proof of the supposed disturbance of consciousness is furnished by the respondent's obvious helplessness, which led to his fainting-fit. He could easily have altered his position or done something to avoid fainting from discomfort, without necessarily stepping outside his role. The remark that he had no appetite at the beginning of his hunger-strike is also significant. All this suggests that the intention to simulate insanity became a powerful auto-suggestion which blurred his consciousness and in this way influenced his actions regardless of his conscious will. This also gives us the key to his histrionic feats. There are numerous cases known to science of deceptions which started off as conscious and became, by auto-suggestion, involuntary and unconscious, and also much more convincing and consistent. Into this category fall, in particular, all cases of pathological lying (*pseudologia phantastica*).

[420] These phenomena are observed as a rule in hysterically disposed persons, which is an additional reason for suspecting the respondent of some hysterical degeneracy.

[421] Although certain episodes doubtless came about only as a result of the restriction and blurring of consciousness, it is not surprising that the respondent occasionally dropped the mask and showed an interest in his surroundings that contradicted his apparent apathy.

[422] The most probable hypothesis is that he acted the greater part of his seeming insanity with conscious intent, but that certain elements in the simulation worked on him so convincingly that they acquired the force of an overmastering suggestion and so induced a genuine auto-hypnosis. That these abnormal psychic processes had an injurious effect on his mental activity in other ways is shown by the difference between the work-curve on the second day after simulation ceased and nine days later.

[423] As is clear from the respondent's own statements, the development of simulation was attended by strong affects. Affects always have a disturbing influence on consciousness, as they place undue emphasis on feeling-toned thought-processes and thus obscure any others that may be present. Hence it is understandable that the respondent was not very clear

as to what he wanted to gain by simulation. In our opinion, the initial affects were the source of the overmastering suggestion to simulate that later ensued. That this phenomenon of partly conscious, partly unconscious simulation could come about at all was evidently due to the respondent's hysterical disposition, and the most outstanding feature of this disposition is an abnormal dissociability of consciousness, which, the moment a strong affect appears, can easily lead to mental confusion and the formation of suggestions which are very difficult to combat. Altogether, the psychological mechanism of his simulation seems to us to suggest that the initial psychic weakness was the final cause of the idea of simulation. The respondent was probably aware of the confusion wrought by his emotions, and he may have converted it into the wish to go mad rather than bring more disgrace on his mother through another penal conviction.

[424] However that may be, it is sufficient to show that his simulation had pathological features and that it appears to have been influenced, even in origin, by causes that were not quite normal.

[425] We have no reason to suppose that the same or a similar disturbance of consciousness existed before his imprisonment, that is to say, at the time the offence was committed; moreover, it is very improbable there was any pathological disturbance at that time—unless, of course, one chooses to regard his ordinary state of congenital degeneracy as such a disturbance. Degenerative symptoms of this kind are, however, found in a large number of habitual criminals who must be considered fully responsible in the eyes of the law. On the other hand, we are of the opinion that the psychological state in which the decision to simulate was taken is not quite the same as the one designated by the term "responsibility," because in the former case there was an undeniable predisposition which underlay the wish to simulate and fostered it in such a manner that we must suppose the respondent was acting under abnormal influences which considerably restricted his freedom of will.

[426] We therefore conclude that insanity within the meaning of the law was not present at the time the theft was committed, but that partial responsibility must be assumed for the simulation.

[427] Further, having regard to the fact that the simulation was for the most part conscious, and that a spontaneous twilight state is in consequence precluded, the respondent must also be deemed punishable.

[428] We therefore answer the questions put to us as follows:

[429] 1. The respondent is not at the moment mentally ill.

2. He is, on the other hand, in a condition of psychopathic inferiority with hysterical features.

3. This condition has existed presumably since birth. It does not preclude responsibility for theft; but partial responsibility must be assumed for simulation.

VI

A THIRD AND FINAL OPINION ON TWO CONTRADICTORY PSYCHIATRIC DIAGNOSES

ON THE PSYCHOLOGICAL DIAGNOSIS OF FACTS

A THIRD AND FINAL OPINION ON TWO CONTRADICTORY PSYCHIATRIC DIAGNOSES[1]

[430] It is not so very uncommon for two psychiatric diagnoses to reach contradictory conclusions, especially when, as in the present case, it is a question of the very elastic borderline between complete irresponsibility and partial responsibility. The peculiarity of this case consists firstly in the fact that the medical expert was confronted, not with the defendant herself, but merely with the reports that had previously been passed on her. In adopting this procedure, the authorities were swayed by the reflection that the material already amassed in these reports was so exhaustive that further observation would be superfluous. The medical expert was able to concur with this view. Secondly, the case is of interest inasmuch as it gave rise to a discussion of principle concerning the relation—a very important one in practice—of moral defect to hysteria. The medical expert would like to submit the views expressed in the final opinion for the consideration of his professional colleagues.

[431] Our opinion is based on the existing records, etc., the legal records being specified under “Documents.”

[432] At the same time we have tried to form our own judgment on the basis of two consultations with the defendant in prison.

Questions Asked by the Examining Magistrate

[433] (*i*). May one assume, from the psychiatric reports (Opinions A and B) that Mrs. Z. is totally irresponsible, or is it a case of partial responsibility only?

(*ii*). Was the material at the disposal of the Governors of Asylum B. complete?

Opinion A: November 17, 1904

[434] THE FACTS: Mrs. Z. defrauded two women of 200 marks by telling them she had a ticket in the Hungarian state lottery, and had drawn a high prize (38,000 or 180,000 marks). She now needed the money to pay for her ticket, so that she could collect the winnings.

[435] EXAMINATION: To the examining magistrate the defendant stated that in November 1903 a certain August Baumann had offered her further lottery tickets to the value of 2000 francs. In order to buy them, she had tried to raise the money.

[436] The examination showed, however, that in 1900 and 1901 she had relieved a certain B. [another person] of 4000 francs by telling the same story. Nevertheless, the defendant maintained the existence of Mr. Baumann with such obstinacy that it was at first conjectured she might perhaps be his victim.

[437] Despite exhaustive inquiries, Baumann's existence could not be proved. But as the defendant stuck to her story, and the evidence of several witnesses raised the question of her mental health, the examining magistrate considered it possible that she was suffering from pathological self-deception. For these reasons she was recommended for a medical opinion.

[438] DOCUMENTS: The Opinion was based on the documents then in existence, the following being of special interest: The records of the Cantonal Court of G.; a report from the penitentiary in G., which states: "Z. is a pleasure-seeking, dissolute person and a first-class impostor. Her behaviour in the penitentiary was entirely normal, there was never any sign of a psychic defect"; and, finally, a report from the District Medical Officer of K., September 1904, which assumed an abnormal mental condition and limited responsibility on the grounds of various nervous troubles, such as the unshakable "self-suggestion" of Baumann's existence and the incomplete correction of an anxiety dream she had in prison. In addition, there were a number of important testimonies representing the defendant as mentally abnormal.

[439] Observation began on September 28, 1904, and the Opinion was delivered on November 17. The observation established the presence of hysterical symptoms, and that the belief in Baumann's existence was a pathological self-deception in which the defendant herself believed. She admitted that she obtained the money by fraud, but insisted that she meant to pay it back as soon as she received her winnings.

[440] There were no other disturbances of intelligence and consciousness.

[441] CONCLUSION DRAWN BY THE OPINION: The most important finding is the presence of hysteria. Basic to all hysteria is an hysterical character, which is generally congenital. "Experience shows that persons of this kind habitually lie even when there is no need to, and invent whole stories," which, however, have reality value for the person concerned. "It goes without saying that with constitutionally hysterical persons lying and fraud cannot be judged in the same way as with normal people; they succumb more easily to an already existing tendency to deceive, their lies readily suggest themselves, and many of the checks which prevent normal people from lying and cheating do not operate in these persons."

[442] The Opinion assumed partial responsibility.

[443] CRITICISM OF THE OPINION: The previous history is incomplete, as it is based almost entirely on the documents. That, however, is not the fault of Asylum A., but of its distance from Switzerland, which prevented a personal examination. Examination by letter would have been impossible. The discovery of hysterical symptoms is not particularly difficult, hence the risk of deception is small. Moreover the examining doctors X. and Y. are professionals of good repute. Although greater completeness would have been desirable, the findings are nevertheless not only reliable but sufficient to warrant the above conclusion.

[444] The important question of how far the belief in Baumann's existence influenced her actions is not discussed. If she really believed in Baumann and his lottery tickets, her fraudulent manipulations would be bound to appear much less reprehensible to her, as she could always exculpate herself in her own eyes by telling herself that she would pay the money back again. This kind of reasoning would appeal very much to the weak

character of an hysteric, a fact which ought to have played a considerable part in determining the degree of responsibility. Opinion A seems to assume that the defendant did believe in Baumann. In that case there is an omission in the Opinion which makes the whole conclusion appear doubtful. But if the defendant was lying, if she purposely put the blame on somebody unknown, then the conclusion reached by the Opinion could still be correct, even though it takes no stand on this question.

Opinion B: March 23, 1905

[445] THE FACTS: Mrs. Z. defrauded a certain H. of 700 francs. She told the injured party that she had a ticket in the Budapest lottery, which had won—first 135,000 and then 270,000 francs. On various pretexts of secondary importance she induced H. to give her considerable sums of money from time to time, thus repeating the game as before.

[446] EXAMINATION: At the hearing the defendant again insisted that she had received a lottery ticket from the agent Baumann. In view of the fact that one medical opinion had already been submitted, the examining magistrate thought it advisable to obtain a second.

[447] DOCUMENTS: The Opinion was based on the documents then available (list of documents followed). Private inquiries concerning the defendant were also initiated by the asylum.

[448] This material is much more complete than in Opinion A. We refrain from giving in detail all the valuable points of view arising out of the above material, and refer the reader to the “Conclusions” below. They confirm at some length that the defendant was from the beginning a morally defective psychopath, who already had a variegated record of offences behind her.

[449] Observation began on January 19, 1905, and the Opinion was delivered on March 23, 1905. The period of observation was therefore sufficiently long to warrant a very thorough appreciation of her psychic state. The main finding was again a number of undoubted hysterical symptoms. (The fact that other physical disturbances of a different nature were found in Opinion B is of no special importance: hysterical

symptoms can change very rapidly.) As in Opinion A, no pathological defect of intelligence and no disturbance of consciousness could be demonstrated. The far more thorough investigation of her mental state proved, first and foremost, the existence of an hysterical character with all its subsidiary symptoms—unsociableness, irritability, tendency to lie and to intrigue, bad memory, etc.

[450] Here too the belief in the existence of Baumann proved unshakable (at least to all appearances). The defendant maintained that she had spent the best part of the money on Baumann's tickets. In her relations with those about her she showed her sly and rebellious nature.

[451] CONCLUSIONS DRAWN BY THE OPINION: From the life and behaviour of the defendant, who has an hereditary taint, it is abundantly clear that she suffers from hysteria. Her hysterical character expresses itself in the form of crass egotism. She manifests an extraordinary lack of feeling towards her relatives, her former husband, and her fiancé, both of whom she swindled without scruple. In the sexual sphere she knows no moral restraints. She is pleasure-seeking and extravagant. Her extreme instability and moodiness are characteristic. Her feelings vary inordinately.

[452] She knows what is permitted and what is not, but is totally wanting in moral feeling.

[453] The belief in the existence of Baumann must be regarded as a pathological fraud which she has gradually talked herself into believing.

[454] Her unlawful actions must be regarded as symptoms of her hysterical aberration. She is therefore totally irresponsible. Her illness has developed with her personality. She is therefore incurable.

[455] The defendant is a danger to the community, and it is necessary to protect society from her machinations. Considering the craftiness of her procedure, this would seem best accomplished by permanent internment in a closed institution.

[456] CRITICISM OF THE OPINION: The material leaves nothing to be desired; it is more than sufficient to establish constitutional hysteria. In our view, however, the Opinion goes decidedly too far in its conclusions.

[457] It establishes quite correctly that there is a total lack of moral feelings, but that is not an hysterical symptom and does not belong in any way to the hysterical character. There are thousands of severe hysterics who have very sensitive moral feelings, and there are just as many hardened criminals who show no signs of hysteria. Moral defect and hysteria are two completely different things, which occur independently of one another, as everyday experience shows.

[458] As may be elicited from the Opinion, the defendant is a morally defective person who, besides that, is hysterical. Only her moral defect can lead to criminality, not her hysteria; otherwise all hysterics would be criminals, which is contrary to all experience.

[459] Consequently, the conclusion that the unlawful actions are symptoms of hysteria falls to the ground, and the question of responsibility appears in quite another light, a point to which we shall return later on.

[460] Despite thorough discussion, the question of belief in Baumann does not find a satisfactory solution in this Opinion either. Nevertheless, thanks to its greater thoroughness, one can see much more clearly here that this question is of no particular significance as regards her freedom of action. Before she ever got this idea, the defendant lied, defrauded, indulged in sexual activity to excess, and, in the case of the offence mentioned in Opinion B, acted with full consciousness of defrauding. It therefore seems completely out of the question that any pathological compulsion emanated from this idea.

[461] One could perhaps say that the general idea of fraudulent action depended on belief in the existence of Baumann, supposing that this belief was really present. Be that as it may, it is at any rate certain that the defendant carried out the details of her frauds with clear consciousness. For instance, she journeyed to K., ostensibly to pay for the tickets, but returned after a few days loaded with new clothes and presents.

[462] The correct conclusion to be drawn from Opinion B, therefore, is that she acted unlawfully in consequence of her moral defect. One must, however, agree with the Opinion in so far as the undoubted existence of hysteria had a considerable influence on her actions.

Final Opinion

[463] From the material collected under Opinions A and B, it seems to us proven beyond a doubt that Z. is a morally defective and hysterical person.

[464] Moral defect (moral insanity) is a congenital condition characterized by the absence of moral feelings. Hysteria never causes a moral defect; it can at most mask the existence of such, or exaggerate its pre-existing influence on a person’s actions. Hysteria is a morbid condition, congenital or acquired, in which the affects are exceedingly powerful. Hence the patients are more or less the continual victims of their affects. At the same time, however, hysteria generally determines only the *quantity*, not the *quality*, of the affects. The quality is given by the patient’s character. A soft-hearted person, if she becomes hysterical, will simply burst into tears more easily, a ruthless person will become harder, and one who is inclined to excess will fall victim to her inclinations even more unresistingly than before. It is in this manner that we have to envisage the influence of hysteria on criminal actions.

[465] A person who is morally defective from the beginning and who is or becomes hysterical therefore has even less power of resistance than one who is only morally defective. This behaviour is brought out very nicely in Opinion B. No sooner is she released from prison than the defendant immediately succumbs again to the temptation of fraud. She brings off her coups with consummate skill and has, so far as one can judge, a positively uncanny influence over her victims. As Opinion B rightly remarks, these artful powers of persuasion must be put down to hysteria, for in hysteria there is always so much feeling and such a natural gift for play-acting that, however much they lie and exaggerate, hysterics will always find people gullible enough to believe them. Even doctors are often taken in by their wiles.

[466] Neither of the Opinions has proved that the defendant was acting under the compulsion of a pathological conviction, a delusional idea (Baumann), or a pathological and irresistible instinct. Both stress that she knew her actions were immoral. A clouding of consciousness at the moment of the deed is likewise out of the question.

[467] The defendant simply gives way to her evil inclinations. She acts exactly like any common criminal. Her hysteria fosters her actions and prevents any resolutions to the contrary. It does this because only evil inclinations are present. If good ones were there too, the hysteria would occasionally foster them as well, as happens in hysterical persons who are not morally defective. This shows that the essential thing can only be the moral defect.

[468] Is the defendant legally irresponsible on account of her moral defect?

[469] Every habitual criminal is morally defective, and is thus ill in a scientific sense. The law, however, as it stands at present, claims all individuals who recognize the punishable nature of their actions and who are not acting under an irresistible compulsion.

[470] The juridical conception of irresponsibility therefore includes all psychic abnormalities with the exception of moral defect. So if we adhere to the meaning of the law, moral defect should logically not be taken into account in adjudging the question of responsibility.

[471] In the present case, is the hysteria by itself strong enough to cause total irresponsibility?

[472] As the Münsterling Opinion [B] makes clear, the defendant is morally defective. If such a defect is present and offences are committed, they must naturally be connected first of all with the moral defect, since they are two things that go together unconditionally. If the offences are to arise from hysteria, it must be shown from the character of the offences that they have their roots in hysteria and not in moral defect.

[473] Are the defendant’s offences specifically hysterical?

[474] No proof of this has been furnished. To all appearances it is a question of conscious and intentional fraud, of a kind common among skilled impostors. Its roots lie in evil inclinations and lack of resistance to them. But that is not hysterical. The only point where one might surmise a specifically hysterical motive is the question of Baumann. But it is precisely here that the greatest mistrust is to be recommended. The Baumann swindle served a purpose, and on one occasion it very nearly came off (in K.). Opinion B emphasizes that the defendant once said she

would not let herself be hypnotized, as she was “not obliged to tell the doctors the whole truth.” In view of this remark it may be supposed that she had more insight into her swindles than she was credited with. It therefore behoves us to exercise the greatest caution in regard to the Baumann swindle. On the occasion of the present offence, the undersigned had a lengthy talk with the defendant on this point and ascertained that this time she swindled on purpose, in order to obtain money. Baumann played no part in it at all. She also assured me that she did not possess any tickets, but she still maintains the existence of Baumann to this day with the greatest positiveness and many tears, so that it is extremely difficult to resist the impression of his reality. However, the only point of practical importance here is that in the present instance she swindled on her own account, quite clearly and without beating about the bush, as once before in 1900. It is also clear that no hysterical motivation may be inferred for her offences.

[475] These offences, and particularly their remarkably sure results, must be understood as the co-operative action of moral defect and hysteria, the hysteria being merely an accessory influence in respect of the offence. Owing to the strength of their affects, hysterical persons are always their own victims; they do not belong to themselves, as it were, but to the momentary affect. Consequently, their actions are always being compromised by passing moods. We all know how much these can obscure our judgment and hinder reflection. With a higher degree of hysteria, such as the defendant exhibits, the decisions of the will are always influenced by abnormal affects, which is not the case with normal people, who can calmly weigh the pros and cons of their actions. Hysteria therefore limits the subject’s responsibility.

[476] Accordingly, we answer your questions thus, to the best of our knowledge and conscience:

(*i*). On the basis of Opinions A and B, only a diminished or partial responsibility can be assumed.

(*ii*). The material collected under Opinion B is put together with so much care and thoroughness that one could hardly add anything more than subsidiary details to its completeness.

[477] The standpoint of the Opinion [B] means nothing less, in practice, than an abandonment of the scientific conception of moral defect. The logical conclusion to be drawn would be the exclusion of moral defectives from the legal conception of insanity. In theory this might be described as a retrograde step or concession to the lay psychologist's interpretation of criminal law, and in practice as a lack of consideration for society. We, as doctors of the mentally ill, should pay no attention to either reproach, for our first charge is to watch over the welfare of the state institutions committed to our care. If we, too, now put into practice our theory of the mental sickness of moral defectives, we find that with increasing psychological education of the judiciary our institutions are getting choked with criminals, thanks to our altruistic medical reports. Conditions in an asylum will rapidly become untenable. (Just now in Burghölzli, only one more criminal is needed to make the situation quite impossible.) In this way we ruin the character and reputation of an asylum completely, and no one could blame a respectable family if it did everything in its power not to send an unfortunate mentally sick relative into the villainous hubbub of a criminal ward. The presence of criminals completely poisons the tone of the place, and its spirit as a hospital. In addition, only a very few asylums have the equipment for confining criminals. The more the legal experts realize the futility of the existing criminal practice, the more they will insist upon getting rid of their permanently incorrigible clients by interning them in a lunatic asylum, on the increasingly popular plea that society must be protected. Naturally criminal justice wants that, but why must the asylum suffer for it? The asylum should never become the executive organ of criminal law. By relieving criminal justice of inconvenient elements we do not make them better, we merely ruin our asylums. So long as society is unwilling to alter the laws relating to criminal justice, it must also discover to its cost that, as a result of the rapidly increasing number of partially responsible persons, the most dangerous criminals are turned loose against it at ever shorter intervals. Only in this way can the pressing need for reforms be demonstrated to the public.

ON THE PSYCHOLOGICAL DIAGNOSIS OF FACTS[1]

[478] As readers of the *Centralblatt* may be aware, the "psychological diagnosis of facts" has recently been the object of some discussion. The essence of psychological diagnosis consists in bringing to light, by means of associations, the complex of ideas relating to a crime. In our work on "The Associations of Normal Subjects,"[2] Riklin and I put forward the concept of the "feeling-toned complex" and described its effects on the associations; these effects were examined in greater detail in my inaugural paper on "Reaction-Time in the Association Experiment." The discovery of feeling-toned complexes in the associations of insane persons has been of great help to us in our diagnostic work for the past two years, as is apparent from a number of publications by Riklin and myself.

[479] After the publication of my studies in word-association, an article by Wertheimer and Klein appeared in Volume XV of the *Archiv für Kriminalanthropologie und Kriminalistik*, on the psychological diagnosis of facts.[3] The authors discuss, in the main, the possibility of finding, through the associations, the feeling-toned complex relating to a crime committed in the past. As Messrs. Wertheimer and Klein are erroneously described as the "discoverers" of this idea, I would like to clarify the situation by taking this opportunity to remark that, so far as the experiment is concerned, the honour of the title of discoverer belongs to Galton or Wundt. The concept of feeling-toned complexes, however, and the determination of their specific effects on association, derive from the Zurich Clinic, and more particularly from the "Diagnostische Assoziationsstudien" published in the *Journal für Psychologie und Neurologie*, 1904–5. If Wertheimer and Klein had had a little more respect for the workers before them in this field, and had cited the source from which they appropriated their seemingly original ideas, they could

have spared themselves sundry unpleasant discussions (cf. Weygandt's criticism in the latest issue of Aschaffenburg's *Monatsschrift*[4]).

[480] Wertheimer's merit is confined at present to having emphasized a special instance of the feeling-toned complex—crime—and the possibility of discovering it from the associations. I am privately informed that experiments in this direction are in progress, though as yet they do not seem to have advanced much beyond the laboratory stage.

[481] Readers may be interested to know that today I succeeded for the first time in testing out, on a delinquent, our method of discovering complexes, and with excellent results.

[482] A detailed account of the case will appear in a forthcoming issue of the *Schweizerische Zeitschrift für Strafrecht*.[5] I permit myself only a brief report on the case now:

[483] Yesterday evening an elderly gentleman came to see me, obviously in a state of great agitation. He told me that he had staying with him a young man of eighteen, whose guardian he was. Some weeks ago he noticed from time to time that small sums of money were missing from his cashbox, now amounting to over 100 francs. He at once informed the police, but was unable to bring proofs against any one person. He rather suspected his ward, but had no absolute proof of this. If he knew that his ward was the thief, he would prefer to settle the matter on the quiet, so as to spare the feelings of the boy's highly respectable family. But first he wanted to know for certain whether his ward was really a thief. He now asked me to hypnotize the young man and question him under hypnosis. As can readily be understood, I declined this strange request, but proposed instead an association test, which could be rendered plausible enough in the form of a consultation (the suspected delinquent had wanted to consult me once before on account of mild nervous troubles). His guardian agreed to the plan and this morning the young man turned up for the consultation. I had, of course, previously equipped my list of one hundred stimulus words with the critical words designed to hit the complex. The experiment went off smoothly; but in order to determine the critical reactions still more precisely I decided to employ my reproduction procedure as well. The complex for the theft was then

revealed so plainly by the associations that I was able to tell the young man with quiet assurance: “You have been stealing.” He paled, was completely nonplussed for a moment, and after a little hesitation broke down and tearfully admitted to the theft.

[484] I would merely like to add, in this provisional report, that the effects of a theft complex on the associations are naturally exactly the same as in the case of any other complex of similar emotional intensity. For further details I must refer the reader to the forthcoming publication.

BIBLIOGRAPHY

BIBLIOGRAPHY

The items of the bibliography are arranged alphabetically under two headings: *A*. List of periodicals cited, with abbreviations; *B*. General bibliography, including both books and articles. It has not been possible to establish the full names of some medical writers cited in the early literature.

THE COLLECTED WORKS OF

C. G. JUNG

THE PUBLICATION of the first complete edition, in English, of the works of C. G. Jung was undertaken by Routledge and Kegan Paul, Ltd., in England and by Bollingen Foundation in the United States. The American edition is number XX in Bollingen Series, which since 1967 has been published by Princeton University Press. The edition contains revised versions of works previously published, such as *Psychology of the Unconscious*, which is now entitled *Symbols of Transformation;* works originally written in English, such as *Psychology and Religion;* works not previously translated, such as *Aion;* and, in general, new translations of virtually all of Professor Jung's writings. Prior to his death, in 1961, the author supervised the textual revision, which in some cases is extensive. Sir Herbert Read (d. 1968), Dr. Michael Fordham, and Dr. Gerhard Adler compose the Editorial Committee; the translator is R. F. C. Hull (except for Volume 2) and William McGuire is executive editor.

The price of the volumes varies according to size; they are sold separately, and may also be obtained on standing order. Several of the volumes are extensively illustrated. Each volume contains an index and in most a bibliography; the final volumes will contain a complete bibliography of Professor Jung's writings and a general index to the entire edition.

In the following list, dates of original publication are given in parentheses (of original composition, in brackets). Multiple dates indicate revisions.

*1. PSYCHIATRIC STUDIES

On the Psychology and Pathology of So-Called Occult Phenomena (1902)

On Hysterical Misreading (1904)

Cryptomnesia (1905)

On Manic Mood Disorder (1903)
A Case of Hysterical Stupor in a Prisoner in Detention (1902)
On Simulated Insanity (1903)
A Medical Opinion on a Case of Simulated Insanity (1904)
A Third and Final Opinion on Two Contradictory Psychiatric Diagnoses (1906)
On the Psychological Diagnosis of Facts (1905)

†2. EXPERIMENTAL RESEARCHES

Translated by Leopold Stein in collaboration with Diana Riviere

STUDIES IN WORD ASSOCIATION (1904–7, 1910)

The Associations of Normal Subjects (by Jung and F. Riklin)
An Analysis of the Associations of an Epileptic
The Reaction-Time Ratio in the Association Experiment
Experimental Observations on the Faculty of Memory
Psychoanalysis and Association Experiments
The Psychological Diagnosis of Evidence
Association, Dream, and Hysterical Symptom
The Psychopathological Significance of the Association Experiment
Disturbances in Reproduction in the Association Experiment
The Association Method
The Family Constellation

PSYCHOPHYSICAL RESEARCHES (1907–8)

On the Psychophysical Relations of the Association Experiment
Psychophysical Investigations with the Galvanometer and Pneumograph in Normal and Insane Individuals (by F. Peterson and Jung)
Further Investigations on the Galvanic Phenomenon and Respiration in Normal and Insane Individuals (by C. Ricksher and Jung)
Appendix: Statistical Details of Enlistment (1906); New Aspects of Criminal Psychology (1908); The Psychological Methods of

Investigation Used in the Psychiatric Clinic of the University of Zurich (1910); On the Doctrine of Complexes ([1911] 1913); On the Psychological Diagnosis of Evidence (1937)

*3. THE PSYCHOGENESIS OF MENTAL DISEASE

The Psychology of Dementia Praecox (1907)
The Content of the Psychoses (1908/1914)
On Psychological Understanding (1914)
A Criticism of Bleuler's Theory of Schizophrenic Negativism (1911)
On the Importance of the Unconscious in Psychopathology (1914)
On the Problem of Psychogenesis in Mental Disease (1919)
Mental Disease and the Psyche (1928)
On the Psychogenesis of Schizophrenia (1939)
Recent Thoughts on Schizophrenia (1957)
Schizophrenia (1958)

†4. FREUD AND PSYCHOANALYSIS

Freud's Theory of Hysteria: A Reply to Aschaffenburg (1906)
The Freudian Theory of Hysteria (1908)
The Analysis of Dreams (1909)
A Contribution to the Psychology of Rumour (1910–11)
On the Significance of Number Dreams (1910–11)
Morton Prince, "The Mechanism and Interpretation of Dreams": A Critical Review (1911)
On the Criticism of Psychoanalysis (1910)
Concerning Psychoanalysis (1912)
The Theory of Psychoanalysis (1913)
General Aspects of Psychoanalysis (1913)
Psychoanalysis and Neurosis (1916)
Some Crucial Points in Psychoanalysis: A Correspondence between Dr. Jung and Dr. Loÿ (1914)
Prefaces to "Collected Papers on Analytical Psychology" (1916, 1917)

The Significance of the Father in the Destiny of the Individual (1909/1949)
Introduction to Kranefeldt's "Secret Ways of the Mind" (1930)
Freud and Jung: Contrasts (1929)

‡5. SYMBOLS OF TRANSFORMATION (1911–12/1952)

PART I
Introduction
Two Kinds of Thinking
The Miller Fantasies: Anamnesis
The Hymn of Creation
The Song of the Moth

PART II
Introduction
The Concept of Libido
The Transformation of Libido
The Origin of the Hero
Symbols of the Mother and of Rebirth
The Battle for Deliverance from the Mother
The Dual Mother
The Sacrifice
Epilogue
Appendix: The Miller Fantasies

*6. PSYCHOLOGICAL TYPES (1921)

Introduction
The Problem of Types in the History of Classical and Medieval Thought
Schiller's Ideas on the Type Problem
The Apollinian and the Dionysian
The Type Problem in Human Character
The Type Problem in Poetry

The Type Problem in Psychopathology
The Type Problem in Aesthetics
The Type Problem in Modern Philosophy
The Type Problem in Biography
General Description of the Types
Definitions
Epilogue
Four Papers on Psychological Typology (1913, 1925, 1931, 1936)

†7. TWO ESSAYS ON ANALYTICAL PSYCHOLOGY
On the Psychology of the Unconscious (1917/1926/1943)
The Relations between the Ego and the Unconscious (1928)
Appendix: New Paths in Psychology (1912): The Structure of the Unconscious (1916) (new versions, with variants, 1966)

‡8. THE STRUCTURE AND DYNAMICS OF THE PSYCHE
On Psychic Energy (1928)
The Transcendent Function ([1916]/1957)
A Review of the Complex Theory (1934)
The Significance of Constitution and Heredity in Psychology (1929)
Psychological Factors Determining Human Behavior (1937)
Instinct and the Unconscious (1919)
The Structure of the Psyche (1927/1931)
On the Nature of the Psyche (1947/1954)
General Aspects of Dream Psychology (1916/1948)
On the Nature of Dreams (1945/1948)
The Psychological Foundations of Belief in Spirits (1920/1948)
Spirit and Life (1926)
Basic Postulates of Analytical Psychology (1931)
Analytical Psychology and *Weltanschauung* (1928/1931)
The Real and the Surreal (1933)

The Stages of Life (1930–1931)
The Soul and Death (1934)
Synchronicity: An Acausal Connecting Principle (1952)
Appendix: On Synchronicity (1951)

*9. PART I THE ARCHETYPES AND THE COLLECTIVE UNCONSCIOUS

Archetypes of the Collective Unconscious (1934/1954)
The Concept of the Collective Unconscious (1936)
Concerning the Archetypes, with Special Reference to the Anima Concept (1936/1954)
Psychological Aspects of the Mother Archetype (1938/1954)
Concerning Rebirth (1940/1950)
The Psychology of the Child Archetype (1940)
The Psychological Aspects of the Kore (1941)
The Phenomenology of the Spirit in Fairytales (1945/1948)
On the Psychology of the Trickster-Figure (1954)
Conscious, Unconscious, and Individuation (1939)
A Study in the Process of Individuation (1934/1950)
Concerning Mandala Symbolism (1950)
Appendix: Mandalas (1955)

*9. PART II AION (1951)

RESEARCHES INTO THE PHENOMENOLOGY OF THE SELF

The Ego
The Shadow
The Syzygy: Anima and Animus
The Self
Christ, a Symbol of the Self
The Sign of the Fishes
The Prophecies of Nostradamus
The Historical Significance of the Fish

The Ambivalence of the Fish Symbol
The Fish in Alchemy
The Alchemical Interpretation of the Fish
Background to the Psychology of Christian Alchemical Symbolism
Gnostic Symbols of the Self
The Structure and Dynamics of the Self
Conclusion

*10. CIVILIZATION IN TRANSITION
The Role of the Unconscious (1918)
Mind and Earth (1927/1931)
Archaic Man (1931)
The Spiritual Problem of Modern Man (1928/1931)
The Love Problem of a Student (1928)
Woman in Europe (1927)
The Meaning of Psychology for Modern Man (1933/1934)
The State of Psychotherapy Today (1934)
Preface and Epilogue to “Essays on Contemporary Events” (1946)
Wotan (1936)
After the Catastrophe (1945)
The Fight with the Shadow (1946)
The Undiscovered Self (Present and Future) (1957)
Flying Saucers: A Modern Myth (1958)
A Psychological View of Conscience (1958)
Good and Evil in Analytical Psychology (1959)
Introduction to Wolff’s “Studies in Jungian Psychology” (1959)
The Swiss Line in the European Spectrum (1928)
Reviews of Keyserling’s “America Set Free” (1930) and “La Révolution Mondiale” (1934)
The Complications of American Psychology (1930)
The Dreamlike World of India (1939)

What India Can Teach Us (1939)
Appendix: Documents (1933–1938)

†11. PSYCHOLOGY AND RELIGION: WEST AND EAST

WESTERN RELIGION

Psychology and Religion (The Terry Lectures) (1938/1940)
A Psychological Approach to the Dogma of the Trinity (1942/1948)
Transformation Symbolism in the Mass (1942/1954)
Forewords to White's "God and the Unconscious" and Werblowsky's "Lucifer and Prometheus" (1952)
Brother Klaus (1933)
Psychotherapists or the Clergy (1932)
Psychoanalysis and the Cure of Souls (1928)
Answer to Job (1952)

EASTERN RELIGION

Psychological Commentaries on "The Tibetan Book of the Great Liberation" (1939/1954) and "The Tibetan Book of the Dead" (1935/1953)
Yoga and the West (1936)
Foreword to Suzuki's "Introduction to Zen Buddhism" (1939)
The Psychology of Eastern Meditation (1943)
The Holy Men of India: Introduction to Zimmer's "Der Weg zum Selbst" (1944)
Foreword to the "I Ching" (1950)

*12. PSYCHOLOGY AND ALCHEMY (1944)

Prefatory note to the English Edition ([1951?] added 1967)
Introduction to the Religious and Psychological Problems of Alchemy
Individual Dream Symbolism in Relation to Alchemy (1936)
Religious Ideas in Alchemy (1937)
Epilogue

†13. ALCHEMICAL STUDIES

Commentary on “The Secret of the Golden Flower” (1929)
The Visions of Zosimos (1938/1954)
Paracelsus as a Spiritual Phenomenon (1942)
The Spirit Mercurius (1943/1948)
The Philosophical Tree (1945/1954)

‡14. MYSTERIUM CONIUNCTIONIS (1955–56)

AN INQUIRY INTO THE SEPARATION AND SYNTHESIS OF PSYCHIC OPPOSITES IN ALCHEMY

The Components of the Coniunctio
The Paradoxa
The Personification of the Opposites
Rex and Regina
Adam and Eve
The Conjunction

*15. THE SPIRIT IN MAN, ART, AND LITERATURE

Paracelsus (1929)
Paracelsus the Physician (1941)
Sigmund Freud in His Historical Setting (1932)
In Memory of Sigmund Freud (1939)
Richard Wilhelm: In Memoriam (1930)
On the Relation of Analytical Psychology to Poetry (1922)
Psychology and Literature (1930/1950)
“Ulysses”: A Monologue (1932)
Picasso (1932)

†16. THE PRACTICE OF PSYCHOTHERAPY

GENERAL PROBLEMS OF PSYCHOTHERAPY

Principles of Practical Psychotherapy (1935)
What Is Psychotherapy? (1935)

Some Aspects of Modern Psychotherapy (1930)
The Aims of Psychotherapy (1931)
Problems of Modern Psychotherapy (1929)
Psychotherapy and a Philosophy of Life (1943)
Medicine and Psychotherapy (1945)
Psychotherapy Today (1945)
Fundamental Questions of Psychotherapy (1951)

SPECIFIC PROBLEMS OF PSYCHOTHERAPY

The Therapeutic Value of Abreaction (1921/1928)
The Practical Use of Dream-Analysis (1934)
The Psychology of the Transference (1946)
Appendix: The Realities of Practical Psychotherapy ([1937] added, 1966)

[‡]17. THE DEVELOPMENT OF PERSONALITY

Psychic Conflicts in a Child (1910/1946)
Introduction to Wickes's "Analyses der Kinderseele" (1927/1931)
Child Development and Education (1928)
Analytical Psychology and Education: Three Lectures (1926/1946)
The Gifted Child (1943)
The Significance of the Unconscious in Individual Education (1928)
The Development of Personality (1934)
Marriage as a Psychological Relationship (1925)

[*]18. THE SYMBOLIC LIFE

Miscellaneous Writings

[*] See announcement at end of this volume.

[1] [Translated from *Zur Psychologie und Pathologie sogenannter occulter Phänomene* (Leipzig, 1902). It was Professor Jung's inaugural dissertation for his medical degree and was delivered before the Faculty of Medicine, University of Zurich. The 1902 title-page stated that the author was at that time "First Assistant Physician in the Burghölzli Clinic" and that the dissertation was approved on the motion of Professor Eugen Bleuler. The book was dedicated to the author's wife, Emma Rauschenbach Jung (1882–1955). A translation by M. D. Eder was published in *Collected Papers on Analytical Psychology* (London and New York, 1916; 2nd edn., 1917). In the following version, the headings have been somewhat re-ordered and some new headings supplied in brackets in an attempt to clarify the structure of the monograph.—EDITORS.

[2] "Über drei Fälle von 'Hysteria magna' " (1900), p. 928.

[3] *Alterations of Personality* (orig. 1892), p. 2, modified.

[4] *Text-Book of Insanity* (orig. 1879), p. 498, modified.

[5] Richer, *Études cliniques* (1881), p. 483.

[6] Ibid., p. 487; cf. also Erler, "Hysterisches und hystero-epileptisches Irresein" (1879), p. 28, and Cullerre, "Un Cas de somnambulisme hystérique" (1888), p. 356*.

[32] As is well known, the hands and arms during the waking state are never quite still, but are constantly subject to fine tremors. Preyer, Lehmann, and others have shown that these movements are influenced in high degree by the ideas predominating in the mind. For instance, Preyer shows that the outstretched hand will draw small but more or less successful copies of figures that are vividly imagined. These intended tremors can be demonstrated in a very simple way by experiments with the pendulum.

[33] Preyer, *Die Erklärung des Gedankenlesens* (1886).

[34] This is analogous to certain hypnotic experiments in the waking state. Cf. Janet’s experiment, when by whispered suggestions he got a patient to lie flat on the ground without being aware of it. *L’Automatisme psychologique* (1913), p. 241.

[35] Cf. Charcot’s scheme for word-picture composition: (1) auditory image, (2) visual image, (3) motor images, (a) speech image, (b) writing image. In Ballet, *Le Langage intérieur et les diverses formes de l’aphasie* (1886), p. 14.

[84] “Hysterisches und hystero-epileptisches Irresein” (1879), p. 21.

[85] Binet, p. 89: “I may say in this connection that hysterical patients have been my chosen subjects, because they exaggerate the phenomena that must necessarily be found to some degree in many persons who have never shown hysterical symptoms.”

[86] As, for instance, in the roof-climbing of somnambulists.

[87] Delbrück, *Die Lüge;* and Redlich, op. cit. Cf. also the development of delusional ideas in epileptic twilight states mentioned by Mörchen, *Über Dämmerzustände* (1901), pp. 51, 59.

[88] Cf. Flournoy's interesting conjecture as to the origin of H. S.'s Hindu cycle: "I should not be surprised if Marlès' remark on the beauty of the Kanara women were the sting, the tiny jab, which aroused the subliminal attention and riveted it, quite naturally, on this single passage and the two or three lines that followed it, to the exclusion of all the much less interesting context" (Swiss edn., p. 285).

[89] Janet says (*The Mental State of Hystericals*, orig. 1893, p. 78); "It is from forgetfulness that there arise, not always, but very often, the supposed lies of hysterical subjects. In the same way we can also explain their caprices, their changes of mood, their ingratitude, in a word their inconsistencies, for the connection of the past with the present, which gives seriousness and unity to conduct, depends largely upon memory."

[90] Cf. Freud, *The Interpretation of Dreams*, p. 593: "The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgment that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep."

[91] Binet, *Alterations*, pp. 93f., modified.

[92] *L'Automatisme psychologique*, p. 329: "Another consideration emphasizes the resemblance between these two states, namely, that subconscious acts have a kind of hypnotizing effect, and one that helps by their very performance to induce somnambulism."

[93] Ibid., p. 329.

[94] Gustave Flaubert made literary use of this falling asleep at the moment of supreme excitement in his novel *Salammbô*. When the hero, after many struggles, at last captures Salammbô, he suddenly falls asleep just as he touches her virginal bosom.

[95] Cases of emotional paralysis may also come into this category. Cf. Baetz, "Über Emotionslähmung" (1901), pp. 717ff.

[96] Hagen, "Zur Theorie der Hallucination" (1868), p. 17.

[97] "Über hysterische Schlafzustände" (1892), p. 59.

[117] Flournoy, p. 31.

[118] *Alterations*, p. 139.

[119] Cryptomnesia should not be confused with hypermnesia. By the latter term is meant the abnormal sharpening of the powers of memory, which then reproduce the actual memory-images themselves.

[120] Cf. Nietzsche, *Ecce Homo* (trans. by Ludovici), pp. 101f.: "Has any one at the end of the nineteenth century any distinct notion of what poets of a stronger age understood by the word 'inspiration'? If not, I will describe it. If one had the smallest vestige of superstition left in one, it would hardly be possible completely to set aside the idea that one is the mere incarnation, mouthpiece, or medium of an almighty power. The idea of revelation, in the sense that something which profoundly convulses and upsets one becomes suddenly visible and audible with indescribable certainty and accuracy, describes the simple fact. One hears–one does not seek; one takes–one does not ask who gives; a thought suddenly flashes up like lightning, it comes with necessity, without faltering–I have never had any choice in the matter."

[121] Ch. XL, “Great Events” (trans. by Common, p. 180, slightly modified). (Orig. 1883.)

[122] Vol. IV, p. 57, headed: “An Extract of Awe-Inspiring Import from the Log of the Ship *Sphinx* in the Year 1686, in the Mediterranean.” (Orig. 1831–39.) [Cf. par. 181, below.—EDITORS.]

[123] In *Ecce Homo:* “There is an ecstasy so great that the tremendous strain of it is at times eased by a storm of tears, when your steps now involuntarily rush ahead, now lag behind; a feeling of being completely beside yourself, with the most distinct consciousness of innumerable delicate thrills tingling through you to your very toes; a depth of happiness, in which pain and gloom do not act as its antitheses, but as its condition, as a challenge, as necessary shades of colour in such an excess of light.” [Cf. Ludovici trans., p. 102.]

[128] *From India to the Planet Mars*.

[129] “… the rapid and confused gibberish whose meaning can never be ascertained, probably because it really has none, but is only a pseudo-language.” Flournoy, p. 199. “… analogous to the gibberish which children use sometimes in their games of ‘pretending’ to speak Chinese, Indian, or ‘savage’…” (p. 159, modified).

[130] Ibid., p. 405.

[131] For a case of this kind see Krafft-Ebing, *Text-Book of Insanity* (orig. 1879).

[132] Loewenfeld (*Hypnotismus*, p. 289) writes: “The restriction of associative processes to, and the steady concentration of attention on, a definite field of representation can also lead to the development of new ideas which no effort of will in the waking state would have been able to bring to light.”

[133] Zschokke, *Eine Selbstschau* (1843), PP. 227ff.

[134] Gilles de la Tourette (quoted in Loewenfeld, p. 132) says: “We have seen somnambulistic girls, poor, uneducated, and quite stupid in the waking state, whose whole appearance altered as soon as they were put to sleep. Before they were boring, now they are lively and excited, sometimes even witty.”

[135] (Added 1978.) The version published in the *Gesammelte Werke*, Band I, gives for par. 150 the following concluding paragraphs (tr. Lisa Ress), from a later printing of the monograph:

I am far from believing that with this work any sort of final and scientifically satisfying result has been achieved. Primarily, my intention has been to counter general opinion, which dismisses so-called occult phenomena with a contemptuous smile, by demonstrating the manifold connections between these phenomena and the subjects covered by medicine and psychology, as well as to refer to the many important questions which this unexplored territory holds for us. Impetus for this work was given me by the conviction that in this area a rich harvest for experiential psychology is ripening, as well as by the awareness that our German science has not concerned itself sufficiently with these problems. This latter reason also induced me to lead off with the investigation of a case of somnambulism belonging to the purely pathological, so as to locate the place of somnambulists in relation to pathology in general.

I hope that in this sense my work will aid science in preparing a way toward the progressive elucidation and assimilation of the as yet extremely controversial psychology of the unconscious.

[1] [First published as “Kryptomnesie,” *Die Zukunft* (Berlin), 13th year (1905), L, 325–34.—EDITORS.]

[2] I call “unconscious,” in the widest sense, everything that is not represented in consciousness, whether momentarily or permanently.

[2a] [The phrases “feeling-toned complex” and “feeling tone” translate the German “gefühlsbetonter Komplex” and “Gefühlston.” Although it might be justifiable to follow H. G. and Cary F. Baynes and translate the first phrase as “emotionally-toned” complex (cf. Jung, “On Psychical Energy,” in *Contributions to Analytical Psychology*, p. 9), the Editors have decided, in keeping with the general policy of this edition, to retain the original terminology on account both of its historical interest and of Jung’s consistent use of the term in his later works. In a re-statement of his theory of complexes published in 1934 (see “A Review of the Complex Theory,” Coll. Works, 8, par. 201), Jung defines the feeling-toned complex as “the image of a certain psychic situation which is strongly accentuated emotionally.” From this it is clear that the word “feeling” is not used in the later technical sense to designate one of the four psychic functions, but in a more generalized way. It is in the latter sense that the terms “feeling tone” and “feeling-toned complex” will be used throughout the collected edition.—EDITORS.]

[13] Krafft-Ebing speaks of “abnormally increased emotional impressionability.” *Text-Book of Insanity* (orig. 1879), p. 52. E. Müller (“Über Moral Insanity,” 1899, p. 342) writes: “It is unanimously emphasized that the emotional reactivity is reduced or abolished, that there is emotional blunting or even complete loss of emotion.” P. 344: “The restrictive checks which the patient’s egotistic strivings meet with in the legal rights of other people lead to bad moods and affects, resulting in great emotional irritability.” This contradiction is not the fault of the author but of his material. Its symptomatology is so extremely contradictory because under the term “moral insanity” are included cases of widely different provenance which merely happen to have the symptom of moral defect in common.

[16] In such a gross disturbance as this, practice is a factor that can be left out of account.

[17] [Professor Jung was evidently contemplating a single paper at this time. As his subsequent publications show, however, he and his collaborators published several. Cf. “The Psychopathological Significance of the Association Experiment” and other papers grouped under “Studies in Word Association” in *Experimental Researches* (Coll. Works, 2); also “The Psychology of Dementia Praecox” (Coll. Works, 3).—EDITORS.]

[22] Raecke, “Hysterischer Stupor bei Strafgefangenen” (1901); A. Westphal, “Über hysterische Dämmerzustände” (1903); and Lücke, “Über das Ganser’sche Symptom” (1903).

[23] Of the 58 cases of simulation I collected, senseless answers corresponding to the Ganser complex were given in 29. The wide incidence of this symptom, which is the distinctive feature of the Ganser complex, is of importance in evaluating the state we are discussing.

[24] Schürmayer (*Lehrbuch der gerichtlichen Medicin*, orig. 1850, p. 378) says: “Very often a bad conscience has such a powerful effect on man’s psychic life that it can feign the appearance of mental suffering. Dejection and irritable moods are found in practically all delinquents who are not

professional criminals. Brooding is very common with them; for weeks on end they find no rest at night; they deteriorate physically, refuse nourishment, suffer from phobias, hallucinations, etc. Not only if they deny their crime do they become like this, but also if they confess it. They give quite absurd answers at the trial and are brought to the brink of despair under cross-examination."

[25] [The case is detailed in the following paper.—EDITORS.]

[26] Laurent, *Étude sur la simulation* (1866).

[27] As far back as 1856, Richarz, one of the experts in the Stockhausen case, expressed the view that outward behaviour exerts a great influence on mental activity. "Über psychische Untersuchungsmethoden" (1856).

[3] The curve was so plotted that the number of additions carried out per minute was written down as one co-ordinate. Correlatively, the number of errors was also plotted in a curve. The curves were appended to the medical opinion. In place of the curves I give here only the average figures as a guide:

	June 10	*June 19*
Average performance per minute	28.1	32.4
Average per minute for 1st half of total number	27.4	31.9
Average per minute for 2nd half of total number	28.9	32.9
Error in total number of additions	11.2%	4.0%
Errors per minute for 1st half of additions	1.5	1.1
Errors per minute for 2nd half of additions	4.7	1.5

BOLLINGEN SERIES XX

PRINCETON UNIVERSITY PRESS

PUBLISHED BY PRINCETON UNIVERSITY PRESS, PRINCETON, NEW JERSEY

First Princeton / Bollingen Paperback printing, with corrections, 1981

THIS EDITION IS BEING PUBLISHED IN THE UNITED STATES OF AMERICA FOR BOLLINGEN FOUNDATION BY PRINCETON UNIVERSITY PRESS AND IN ENGLAND BY ROUTLEDGE & KEGAN PAUL, LTD. IN THE AMERICAN EDITION, ALL THE VOLUMES COMPRISING THE COLLECTED WORKS CONSTITUTE NUMBER XX IN BOLLINGEN SERIES. THE PRESENT VOLUME IS NUMBER 2 OF THE COLLECTED WORKS AND IS THE SEVENTEENTH TO APPEAR.

LIBRARY OF CONGRESS CATALOGUE CARD NUMBER: 75–156
ISBN 0-691-09764-X
ISBN 0-691-01840-5 pbk.
MANUFACTURED IN THE U.S.A.

EDITORIAL NOTE

Jung's creative use of association tests was a part of the pioneering research going on at the Burghölzli in Zurich under the rigorous aegis of Eugen Bleuler at the beginning of this century. Freud's investigations, at the time known though little accepted, were clearly in Jung's mind as he observed the perplexing behaviour of associations; so instead of brushing these to one side and considering them only as aberrant features or as "failures to react" amongst classifiable groupings, he applied the interpretative method and formulated the theory of "complexes." Thus he rescued the association method from "scientific pedantry … and reinvested it with the vitality and interest of real life."[1] The papers in this volume marked, in their day, a revolutionary advance in the use of experimental techniques. All Jung's writings setting out his experimental point of departure and method are included in this volume. Another work of major importance in which the tests were used incidentally is placed in Volume 3 of the Collected Works: Jung's celebrated investigation of dementia praecox. In "On Simulated Insanity," in Volume 1, Jung uses the more formal surface classification of associations, and in a later paper, "A Review of the Complex Theory," in Volume 8, he gives his mature reflections on the place of association studies in his general view of psychic structures and processes.

Perhaps the most vivid account of the association theory will be found in the Tavistock Lectures (1936),[2] in Volume 18.

*

The principal contents of this volume are Jung's six contributions to the famous Studies in Word Association *(Diagnostische Assoziationsstudien)*. The experiments underlying the Studies were carried out under Jung's direction at the Psychiatric Clinic of the University of Zurich, beginning about 1902. Jung at that time was senior assistant staff physician at the Burghölzli Mental Hospital (where the Clinic was); its director was Eugen

Bleuler. The Studies appeared from 1904 to 1910 in the *Journal für Psychologie und Neurologie;* they included contributions also by Bleuler, Franz Riklin, K. Wehrlin, Emma Fürst, Ludwig Binswanger, and Hermann Nunberg.[3] They were reprinted in two volumes, 1906 and 1909. The entire series was translated by a leading British psychoanalyst, M. D. Eder, in a single volume, *Studies in Word-Association*, published by William Heinemann, London, 1918, and Moffat Yard, New York, 1919 (reissued in a facsimile reprint, 1969). The Eder translation has been consulted in the preparation of the present volume.

Jung's lectures under the heading "The Association Method" at Clark University in 1909 were translated by the American psychoanalyst A. A. Brill immediately afterwards for the *American Journal of Psychology* and for a volume issued by the University (both 1910). With little or no change, they were included by Constance E. Long when she edited Jung's *Collected Papers on Analytical Psychology* (1916). The Brill translation has also been consulted for the present volume.

The three other association studies in Part I of this volume appear for the first time in English. "The Psychopathological Significance of the Association Experiment" was Jung's inaugural lecture upon his appointment to a University lectureship. The three studies in Part II originally appeared in American and British journals, two of them being collaborations with American psychiatrists who came to the Burghölzli to participate in research. Four of the brief works in the appendix are also appearing for the first time in English; the fifth was originally published in Sydney, Australia.

In one or two details, the present translation does not follow the terminology evolved in other volumes of the Collected Works; these are cited in footnotes. The translation of "The Association Method" and "The Family Constellation" was completed after Dr. Stein's death (1969) by Jean Rhees and revised (as the entire volume has been) by Diana Riviere.

Acknowledgment is made to Professor C. A. Meier, of Zurich, for editorial advice and for the loan of a diagram reproduced in the first paper in Part II.

The Editors are deeply indebted to Dr. Stein and Miss Riviere for undertaking the difficult translation of these studies, with their exceptional problems of terminology and of rendering the stimulus- and reaction-words in the tests. The German originals of the lists of test words will be available in due course in the Swiss edition of Jung's collected works.

*

In the 1981 reprint, the Editors are grateful to the Editorial Committee of the *Gesammelte Werke,* in Zurich, for corrections that came to their notice in the preparation of Band II., *Experimentelle Untersuchungen* (1979). Because of the technical character of the contents of this volume, the locations of the chief of these are noted: p. 189, line 9; p. 255, n. 47; p. 276, no. 45; p. 281, no. 27; p. 300, no. 100; p. 485, n. 3, end; p. 606, par. 1362 and no. 3; p. 610, no. 10 and n. 4; p. 613, n. 5. On p. 431, Case G, the datum under "I" has been retained as 165.0, as in the original publication, but we note that the Zurich editors construe it as 16.5.

STUDIES IN WORD ASSOCIATION

THE ASSOCIATIONS OF NORMAL SUBJECTS[1]

by C. G. Jung and Franz Riklin

[1] For some time past, attention has been paid in this clinic to the process of association. In order to produce scientifically useful material for this, my director, Professor Bleuler, has compiled a list of 156 stimulus-words and experimented with them on all types of psychosis. In these experiments a very considerable difficulty soon presented itself. There existed no means of precisely and quantitatively separating association in abnormal subjects from that in normal ones. No work had been done giving any facts on the range of normal subjects and formulating the apparently chaotic coincidences of association into rules. In order to fill this gap to some extent and thereby to pave the way for experiments on pathological associations, I decided to collect more material on association in normal people and at the same time to study the principal conditions involved. I carried out this plan with my colleague, Dr. Riklin.

[2] The main experimental methods are as follows: Initially we collected associations from a large number of normal people, with the intention, first, of examining the reactions to see whether they are at all subject to any law; and, next, of discovering whether individual patterns occur, i.e., whether any definite reaction-types are to be found. We combined with this a second experiment of a general psychological nature.

[3] The mechanism of association is an extraordinarily fleeting and variable psychic process; it is subject to countless psychic events, which cannot be objectively established. Among the psychic factors that exert the main influence on the mechanism of association, *attention* is of cardinal importance. It is the factor that in the first place directs and modifies the process of association; it is also both the psychic factor that can most easily be subjected to experiment and the delicate affective apparatus that reacts first in abnormal physical and mental conditions and thereby modifies the associative performance.

[4] Attention is that infinitely complicated mechanism which by countless threads links the associative process with all other phenomena of the psychic and physical domain in consciousness. If we know the effects of attention on the process of association, then we also know, at least in general, the corresponding effects of every psychic event that attention is capable of affecting.

[5] These considerations led us to investigate the effects of attention on the process of association, hoping to clarify as precisely as possible the following questions:

1. What are the laws governing the range of association in normal subjects?

2. What are the direct effects of attention on the association process? In particular, does the valency of the association decrease with the distance from the focus of consciousness?

[6] Our experiments have revealed a series of facts that not only encourage us to follow the paths on which we have set out into psychological regions but also, as we believe, fit us to do so.

C. G. JUNG

PART ONE

I. GENERAL EXPERIMENTAL PROCEDURE

[7] The experiments were carried out alternately by the two authors so that each one in turn undertook a series of experiments on the subjects concerned. Altogether thirty-eight people took part: nine educated men, fourteen educated women, seven uneducated men, and eight uneducated women; the age-bracket was 20–50 years. Care was taken to use, as far as possible, normal subjects for the experiment. This, however, led to unexpected difficulties, particularly with the educated subjects, as precisely on this level the concept of normality must be very elastic. Nevertheless we hope we have not deviated too far from the norm in our selection of subjects for experiment. We give the numbers of the subjects in detail and in many cases combine with this a short description of the personality, which will facilitate the understanding of possible anomalies. Naturally the two authors have also carried out the experiment on each other.

[8] In noting associations we have entirely limited ourselves to those produced by calling out stimulus-words. We used altogether four hundred different stimulus-words. These, grammatically classified, are as follows:

nouns	231
adjectives	69
verbs	82
adverbs and numerals	18

[9] The number of syllables was not taken into account (the stimulus-words have one, two, or three syllables). Nor were the stimulus-words arranged in definite categories as Sommer, for instance, has arranged them. On the contrary, as much care as possible was taken to see that stimulus-words of similar forms or meaning should not follow each other, so as to avoid the subject adapting to a particular topic after one or two reactions. Through an unfortunate coincidence it happened that

among the first hundred stimulus-words there were about thirty that can easily be associated according to temporal or spatial co-existence; in the second hundred there are only about twenty of these, which caused a notable difference of the co-existence association in the first and second hundred. The shortage of stimulus-words of this kind is made up by verbs. It was considered important completely to exclude difficult and rare words, in order to prevent mistakes or lengthened reaction-time due to lack of knowledge on the part of the subjects. The stimulus-words were therefore taken as far as possible from everyday life.

[10] This consideration was all the more essential for us, as with most of our subjects we had to work under somewhat abnormal linguistic conditions. In German-speaking Switzerland the vernacular consists, as is well known, of the Swiss-German dialect or dialects, which not only deviate considerably from standard German but also show significant phonetic differences among themselves. In the schools children learn standard German as if it were a foreign language. In later life educated people gain a fairly complete knowledge of and facility in the German language. The uneducated man, however, unless he has spent a considerable time in Germany, retains at best those German phrases that he has learned at school and later learns little or no more. Nevertheless, literary German is familiar to him in printed or written form and he also understands it as a spoken language without being able to speak fluent, correct standard German himself. We tried therefore in many cases to call out the stimulus-words in the dialect form, but we soon noticed that the uneducated subjects did not understand dialect words as well as standard German. They reacted to the dialect words more laboriously and tried to react in standard German. This somewhat paradoxical phenomenon can be explained by the fact that Swiss-German is a purely acoustic-motor language, which is very rarely read or written.

[11] Everything printed or written is in standard German. The Swiss is therefore not used to experiencing words individually but knows them only in acoustic-motor connection with others. If he has to say a single word without an article he will usually choose the standard German form. We therefore avoided dialect words completely in our experiments. In most cases a correct standard German reaction was given, but any

reactions that were in dialect were fully accepted. The reactions were, of course, written down in the form in which they were given. To subjects who had never taken part in such experiments, their significance was first explained and practical examples of how they had to react were demonstrated to them. Not a few of the uneducated subjects thought that it was a kind of question-and-answer game, the point of which was to find an appropriate word connection to stimulus-words, e.g., *house / housecat, wild / wild cat*. The experiments were never started till it was certain that the subjects understood the experiment. We stress that a case of not understanding never occurred and that general lack of intelligence was much less disturbing than affects, particularly a fairly frequent emotional obtuseness. It is of some significance that many of the uneducated came with a certain "schoolroom" attitude and a certain correct and stiff demeanour.

[12] We organized our experiments as follows: The *first two hundred reactions* were noted without further conditions. The reaction-time was measured with a 1/5-second stop-watch, which we started on the accented syllable of the stimulus-word and stopped on the uttering of the reaction.[2] We do not, of course, presume to have in any way measured complicated psychological times by this simple procedure. We were merely concerned with establishing a general idea of a roughly average reaction-time which is in many cases not without importance, being very often of value in the classification of reactions.

[13] After two hundred reactions, these were as far as possible classified, with the help of the subjects. With educated subjects this was always done; with uneducated subjects, who only rarely have any capacity for introspection, it was of course impossible. We had to limit ourselves to having the connection explained in particularly striking associations. The results of the experiment were divided into a first and second hundred and these were written down separately. During the experiment the psychic state of the subject was as far as possible established, both objectively and subjectively. If for any reason physiological fatigue occurred, we waited till the next day before doing the second experimental series. With the educated subjects fatigue almost never

occurred during the first experiment, so that we could continue at once with the second series in nearly every case.

[14] The *second series of experiments* consisted of one hundred reactions which were recorded under the condition of internal distraction. The subject was asked to concentrate his attention as much as possible on the so-called "A-phenomenon" (Cordes) and at the same time to react as quickly as possible, i.e., with the same promptness as in the first experiment. By the "A-phenomenon" we understand, with Cordes,[3] the sum of those psychological phenomena that are directly stimulated by the perception of acoustic stimulus. To establish whether the subject had observed the A-phenomenon he had occasionally to describe it after the reaction, and this was noted. On completion of this experiment new classifications were again made. Of course, for this experiment only educated people could be used and of these unfortunately only a selection, because it takes a certain psychological training to be able to observe attentively one's own psychic phenomena.

[15] The *third experimental series* was sometimes not carried out till the second day. It consisted of one hundred reactions and was based on the condition of external distraction. The distraction in this experiment was brought about in the following way: The subject had to make pencil marks of about one centimetre, in time with a metronome. The beat for the first fifty reactions was 60 per minute and for the second fifty reactions 100 per minute. The classification results of the first fifty reactions and the second fifty were recorded separately and for ease of calculation brought to one hundred. With a very few subjects the metronome was speeded up at every twenty-fifth reaction in order to exclude an all too quick habituation. The beat was in these cases increased from 60 to 72 and from 100 to 108 per minute.

[16] The factor of habituation, in any case, unfortunately plays a large part in these experiments, as one would expect. Many people very quickly get used to a purely mechanical activity in which, in the second phase of the experiment, only the beat changes. It is difficult to introduce other disturbing stimuli of equal continuity and variability without adducing

word-images, particularly when one does not wish to make too great demands on the intelligence and will-power of uneducated subjects.

[17] In trying to find a suitable disturbing stimulus we were above all intent on excluding that which might have had an excitatory effect on verbal imagery. We think we did exclude such effects by our experimental procedure.

[18] From these experiments three hundred to four hundred associations, on an average, were obtained from every subject. We also tried to supplement our material in other directions, in order to obtain a certain connection with Aschaffenburg’s results, and for this purpose we took associations from some of our subjects in a condition of obvious fatigue. We were able to obtain such reactions from six subjects. Associations were also taken from one subject in a state of morning sleepiness after a night of undisturbed sleep, in which the factor of fatigue was completely excluded. With one subject associations were taken when he was in a state of acute moodiness (irritability) without fatigue.

[19] In this way we obtained about 12,400 associations.

II. CLASSIFICATION

1. GENERAL

[20] Anyone with practical experience of work on association has been confronted with the difficult and unrewarding task of classifying the results of the experiments. On the whole we agree with Cordes[4] when he says that in earlier association experiments the false assumption prevailed that the fundamental psychological phenomenon corresponds to the stimulus-word and that the connection between stimulus-word and reaction is an “association.” This somewhat too simple interpretation is at the same time too pretentious, for it maintains that in the connection between the two linguistic signs there is also a psychological connection (the association). We do not, of course, share this point of view but see in the stimulus-word merely the stimulus in the strict sense of the word and in the reaction merely a symptom of psychological processes, the nature of which we cannot judge. We do not, therefore, claim that the reactions

we describe are associations in the strictest sense; we even wonder if it would not be altogether better to drop the word “association” and talk instead of *linguistic reaction*, for the external connection between stimulus-word and reaction is far too crude to give an absolutely exact picture of those extraordinarily complicated processes, the associations proper. Reactions represent the psychological connection only in a remote and imperfect way. Thus, when describing and classifying linguistically expressed connections, we are not then classifying the actual associations but merely their objective symptoms, from which psychological connections can be reconstructed only with caution. Only in psychologically educated subjects is the reaction what it really should be—namely, the reproduction of the next idea; in all others a distinct tendency to construct something is mixed with the reaction so that in many cases it is the product of deliberation, a whole series of associations. In our association experiments we stimulate the language apparatus. The more one-sided this stimulus is, the greater the number of linguistic connections that will appear in the reaction. As we shall see, this is mainly the case with educated subjects, from whom a finer differentiation of psychological mechanisms, and therefore a greater ability for isolated application, can *a priori* be expected. One must therefore guard against the fallacious assumption that the educated subject has in any way more external associations of ideas than the uneducated.[5] The difference will be a psychological one, as in uneducated subjects other psychological factors insinuate themselves. In the second part of this paper we shall refer to this difference.

[21] As long as we still know so little about the connection between psychic events, we must refrain from formulating the principles for a classification of external phenomena from inner psychic data. We have therefore confined ourselves to a simple logical classification, to which as a precaution it is in our view essential to limit oneself, till we are able to derive empirical laws from psychic associations.[6] The logical principles of classification must also be adapted to the special experimental conditions, that is, to the verbal reaction. We must therefore, in classifying the associations, take into account not only the logical quality but also, if possible, all those external circumstances

occurring as a result of this particular experimental design. The use of the linguistic acoustic brain mechanism naturally is not without influence on the associations. The purely intrapsychic association cannot become the object of another's consciousness without being transformed into the familiar symbolism of language. Thus a completely new element is added to simple association, which exerts a great influence on the latter. In the first place, the results will be determined by the subject's verbal facility; i.e., James Mill's generally valid "law of frequency" directs the reaction even more selectively towards what one is accustomed to. Thus one of the chief principles of our classification will be that of verbal facility.[7]

[22] We proceeded with the classification of associations essentially according to the Kraepelin-Aschaffenburg scheme. We preferred this system to others because in our opinion it is heuristically the most valuable. When Ziehen describes the Kraepelin-Aschaffenburg attempt at classification as a failure, this is surely a rather strong term. No one will maintain that Aschaffenburg's classification is exhaustive; Ziehen would not want to claim that even for his own.

[23] Ziehen's classification has certainly opened up most valuable vistas, but it is itself not completely satisfactory. First of all, the differentiation between "jumping association" and "judgment association" is a very doubtful one, if it is completely dependent on the presence or absence of the copula, a fact which Claparède[8] also strongly criticizes. The complete failure of Aschaffenburg's schema should first be proved, but this has in fact not been done; on the contrary, the results based on this classification are very encouraging, so that at present one can still venture to use it, although bearing in mind its one-sidedness. The other schemas of classification are, however, biased in other ways. The criticism that Aschaffenburg's schema is biased on the side of logic is not valid, as it makes sufficient allowance for logical data as well as for sensual and perceptual connection, and also for the linguistic factor. Faced with reactions in the form of sentences, however, the schema is more or less powerless. On the other hand it must be stressed that with normal subjects sentences occur very rarely. One factor of great practical significance deserves to be stressed. Aschaffenburg's schema has been tested on a great deal of material, part of it pathological, and has proved

itself of value. His *conditio sine qua non* is not the subsequent questioning of the subjects about the reaction phenomenon, as in the schemas of Ziehen, Mayer and Orth, and Claparède; it also allows at least an approximately correct classification without the help of the subject, which is of particular importance in psychopathological experiments.

[24] As we regard this work merely as a preliminary to psychopathological experiments, we have not hesitated to give preference to Aschaffenburg's schema. Those of Münsterberg and Bourdon appear to us as too much weighted on the side of logic; Ziehen's criticism of these, that they are unpsychological because they abstract completely from the context, is valid. Claparède's extremely subtle and penetrating suggestion (p. 226) does, however, deserve serious consideration, but should perhaps first be used on a wider range of material to test its application in practice.

[25] In attempting the classification of acoustic-verbal associations one must never forget that one is not examining images but their verbal symbols. The examination of associations is an indirect one and is susceptible to numerous sources of error caused by the great complexity of the process.

[26] In our experiments we examine the resultant of an appreciable number of psychological processes of perception, apperception, intrapsychic association, verbal comprehension, and motor expression. Each of these activities leaves its traces in the reaction. In view of the great psychological significance of motility, particularly of the speech function, one must attribute above all a main role to linguistic facility. It is mainly this factor that is to be considered in classification. This principle of classification can be criticized for introducing an extremely variable and indeterminable magnitude into the calculation. We must admit that verbal facility is an extremely variable magnitude and that in an actual case it often causes difficulties, and that therefore the logical character of the classification also suffers. It introduces an arbitrary element into the classification that one would like to avoid. But, for the reasons stated above, we have nevertheless, *faute de mieux*, decided on

this mode of classification, taking as a guiding line certain empirical rules that we shall discuss later.

[27] By these restrictions and a thorough consideration of the subject, we hope to have avoided being arbitrary in applying this principle.

[28] In the following nomenclature (flight of ideas, associations etc.,) it must be remembered, after what has just been said, that by this we mean primarily speech-phenomena from which we have allowed ourselves to make deductions about psychological events. Here we are fully aware that we are examining a relatively limited area, that is, associations that are for the most part reflected in the speech mechanism. Thus, when we speak of "flight of ideas," we mean by this the speech phenomenon that is an external manifestation of internal processes. Of course, the psychological event is not necessarily reflected *in toto* in the form of word associations, but is only expressed in linguistic signs of that type when it affects the speech mechanism. In the flight of ideas, the actual thinking would naturally present a totally different picture if it could manifest itself directly. Thus, for example, the flight of ideas resulting from predominantly visual parts of images constitutes a special aspect that can hardly manifest itself adequately enough and is therefore hardly accessible to external examination; particularly in mania, it will as a rule not be accessible to examination, because of the linguistic agitation. We shall find an opportunity in a later publication[9] to discuss the visual form of flight of ideas.

2. SPECIAL CLASSIFICATION

A. Internal Association[10]

[29] (a) GROUPING. We classify under this heading all associations connected by co-ordination, superordination, subordination, or contrast. The perusal of the cases in question leads to the following special classification of co-ordinations:

[30] (α) *Co-ordination*. The two parts are linked by a similarity of content or nature; i.e., a general idea, in which both parts are contained, underlies

them. Examples:

$$\overbrace{\text{lake}\quad\text{ocean}}^{\text{(accumulation of water)}}$$

$$\overbrace{\text{cherry}\quad\text{apple}}^{\text{(fruit)}}$$

$$\overbrace{\text{long}\quad\text{narrow}}^{\text{(measurement)}}$$

$$\overbrace{\text{unjust}\quad\text{faithlessness}}^{\text{(injustice or vice)}}$$

[31] Association by co-ordination must take place within the framework of a clear-cut common general concept, but may be the result of more or less vague similarity. The similarity may be very great, so that only a nuance prevents it from being identical, e.g., *to forbear / leniency*. The similarity can also be very remote, so that the common meaning of the two concepts is not an essential one but a more or less coincidental attribute of the stimulus-image. In such cases the reaction appears very loosely connected with the stimulus-word and thus is distinguished from other co-ordinations. The distance of the association is, as it were, greater. Therefore these co-ordinations can to some extent be separated from those already discussed. In the loosely connected associations two categories can be distinguished:

(1) The stimulus-image is linked to the reaction by a meaningful but otherwise coincidental attribute, e.g.:

father (worried)	worry
play (of child?)	youth
War (peace-league)	Bertha v. Suttner[11]
murderer (to hang)	gallows
sentence (contains something)	content
star (romantic, night?)	romanticism

(2) The stimulus-image is linked to the reaction by an unessential, external, mostly quasi co-existent attribute, e.g.:

pencil (long)	length
sky (blue)	colour
sea (deep)	depth
table (particular shape)	style

[32] These two modes of co-ordination may be called “the connection of images according to internal or external kinship.” The first category contains by far the more significant co-ordinations, and justifies to some extent the terms internal and external. The co-existence of attributes in the second category indicates that the formation of these co-ordinations is due to external association.

[33] As a last category of co-ordination we should like to propose “co-ordination through example.” This category primarily contains reactions that are nothing but the inversions of the two previously discussed patterns:

worry	father (e.g., of the father)
content	sentence (e.g., of the sentence)
colour	sky (e.g., of the sky)
misery	old woman (e.g., an old woman is in misery)

[34] Now, there is a series of reactions to adjectives and verbs which, although it is true that they are not grammatically coordinated to the stimulus-word, can nevertheless perhaps best be grouped with co-ordinations, particularly those of the examples:

to give in	peace-loving
to pay attention	clever man
to despise	wickedness
foreign	emigrant
to pray	pious man
to help	good man

[35] These associations can, if the expression be permitted, be called analytical; they are conceptions that are given, so to speak, implicitly with the stimulus-word to which they have been subordinated or superordinated. But as it is difficult, if not impossible, to distinguish this

relationship with certainty in concrete cases, and as in addition the concept of the whole and the part cannot be applied to adjectives and verbs, we count these reactions also as co-ordination through example, inasmuch as among the possible nouns certain typical ones always appear in the reactions. The reactions in these cases are always extremely general and closely dependent on the stimulus-word.

[36] The special classification of the co-ordinations would then be as follows:

(1) by common general concept
(2) by similarity
(3) by internal relationship
(4) by external relationship
(5) by example

Examples

(1) father	uncle
(2) father	God
(3) father	worry
(4) father	our house
(5) to pay attention	clever man

[37] It must be added that with these examples the rich variety of co-ordinations is by no means exhausted. With individuals who associate intensively according to subjective constellations, a whole series of different co-ordinations, which cannot really be placed in any of these categories, is possible. In these cases one can safely admit one's inability and simply content oneself with the classification "co-ordination." One can console oneself with the idea that the individual possibilities are innumerable and that no schema could ever be invented that would make possible a clear-cut classification of all associations. But there is a number of co-ordinations that could without undue strain be placed under different headings, i.e., they have no clearly defined character; one can either leave it at that or perhaps group these reactions with the type they most resemble. The headings set out above are not meant to be absolute, compulsory categories, but merely a name for empirically found types which, on occasion, however, may merge into each other without sharp

boundaries. More must not be expected in our present state of knowledge of association.

[38] (β) *Subordination*. The reaction is considered as a part or a minor (subordinated) concept of the stimulus-word, e.g.:

tree	beech

[39] Here we include all reactions that specify the stimulus-word, i.e., that represent special instances of the general stimulus-concept, e.g.:

house	house on X street
horse	Mr. X’s horse
railway station	Baden

[40] In some cases there may be doubt whether the association should be considered as subordination or as predicate, e.g.:

food	today’s (viz., food)

[41] *(γ) Superordination*. The reaction is considered as the whole or general concept of the stimulus-word, e.g.:

Ofen[12]	town
cat	animal

Here too the separation from the predicate is difficult, e.g., *thirteen / unlucky number*. Is *unlucky number* in this case a general concept and as such includes thirteen with other unlucky numbers? In our opinion there is a predicate here; on the other hand we would include Aschaffenburg’s association *baptism / ancient custom* as a superordination, as *ancient custom* is a general concept that includes many other subordinate concepts.

[42] (δ) *Contrast*. The concept can be understood without difficulty. The classification and evaluation of the contrasts is much more difficult, however. Contrasts are as a rule very closely associated images, not only conceptually but also perceptually and above all linguistically. There are even languages in which only one and the same word exists to express typical contrasts. It must have been a considerable psychic achievement

in the beginning of language and conscious thought to separate contrasts in speech and concept. Today, however, we have these ancient achievements in thought already formulated in the language; they are taught to us from earliest youth together with the first concepts of speech, with the first songs and reading material. We are verbally very practised in these closely connected concepts, which are very often supported by quotations and rhymes; e.g.:

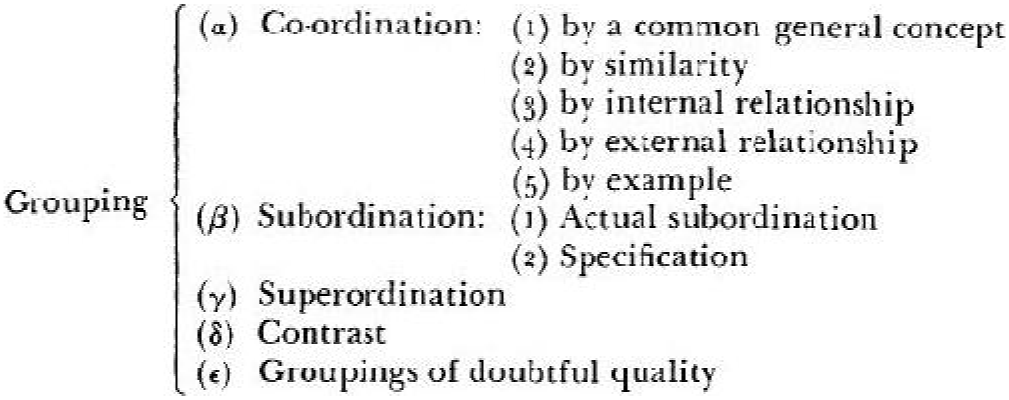
sorrow	joy
pain	pleasure
good	bad
sour	sweet
light	dark

Sauersüss and *helldunkel*[13] are even colloquial words in German. For these reasons we have grouped a large number of common contrasts with external associations. Here we only count associations that are not current, such as:

friendly	angry
good	sinful
animal	plant
sense	stupidity
vengeance	to forgive

[43] In spite of this detailed classification of the groupings there are still associations that cannot be put into any of the subgroups. For these there remains simply the general term “coordination,” e.g., the association *high / silk*. The stimulus-word *high* [German *hoch*] has been understood as a proper name; the bearer of this name [Hoch] has a silk shop; hence the reaction *silk*. This cannot be merely a case of co-existence; the reaction consists of two specific images that are spatially co-existent; it is therefore a rather complicated formation. One could perhaps place it under the heading “co-ordination through external connection,” though admittedly on slight evidence. Therefore it is safest, for the moment, to admit that such co-ordination cannot be further classified.

[44] Summarizing, we arrive at the following schema:



Grouping
- (α) Co-ordination:
  - (1) by a common general concept
  - (2) by similarity
  - (3) by internal relationship
  - (4) by external relationship
  - (5) by example
- (β) Subordination:
  - (1) Actual subordination
  - (2) Specification
- (γ) Superordination
- (δ) Contrast
- (ε) Groupings of doubtful quality

[45] (b) PREDICATE. We include here, in agreement with Aschaffenburg, all judgments, properties, and activities that in any way refer to the stimulus concept as subject or object (summarized by Kraepelin under the name “predicative relationships”).[14]

[46] It is well known that Kant divides judgments into analytic and synthetic.[15] This principle of logical classification is of value to us only in so far as, in an analytic judgment, a part of the concept (i.e., a predicate) is presented that is necessarily inherent in the concept. Thus only that is given which already implicitly exists. But in the synthetic judgment something is added to the concept that is not necessarily already contained in the concept. As regards associative performance the synthetic judgment is in a way superior to the analytic. If we approach this question practically, we find (in so far as this method of classification can in practice be applied at all) that in simple judgment-reactions the analytic judgment exists mainly in the naming of a co-existent perceptible attribute, while the synthetic judgment is mostly a value judgment with a more or less marked ego-reference. Thus we see here a relationship analogous to that between “co-ordination by external relationship” and “co-ordination by internal relationship.” In the association *pencil / length, length* is essentially contained in the concept or is co-existent, while in *father / worry* the concept *worry* adds something new and therefore causes a shifting of concept. We should readily accept the grouping of judgment-reactions into analytic and synthetic if there were not a considerable practical difficulty: we have no way of knowing in the individual case whether the analytic predicate is an essential part of the concept or not. One can only attempt to decide

this question if one can differentiate in individual cases between a concrete and an abstract concept. We know that Ziehen considers that he has done this by direct questioning, even of children. We not only consider this method most unreliable, but also find the distinction between concrete and abstract concepts particularly difficult. If I give a name to a mental picture, then the picture consists of a condensation of many memories, whose more concrete or more abstract aspect depends on minimal differences of perceptual vividness. In many cases even psychologically educated people would be at a loss if they had to decide whether, for example, in *house / roof* they had visualized a concrete or an abstract roof. Of course we are far from denying the existence of abstract concepts; but in concrete cases of acoustic-verbal experiments we cannot help suspecting that the so-called abstract concepts are merely words that lack individual content, only not so much because they are abstract concepts as that they are mostly linguistic formations of a motor kind, in which the other sense-impressions participate only very slightly.

[47] For the answer to the question whether we are faced with an analytic or synthetic judgment we should have to know exactly whether the thought was concrete or abstract: e.g., *snake / green* is objectively entirely synthetic. It is not necessary to think of *green* together with *snake;* only in the case of the image of a definite snake must green be already implicit, in which case it would be an analytic judgment. Apart from these reservations, there are other, mainly practical, difficulties which interdict this mode of classification.

[48] In order to arrive at a special classification of the predicate we must consider the different possibilities:

(1) The stimulus-word is a noun, the reaction an adjective.
(2) The stimulus-word is an adjective, the reaction a noun.

[49] We have no reason to separate these two cases, any more than the other forms of predicative connection:

(1) The stimulus-word is the subject, the reaction its active or passive activity.
(2) The stimulus-word is the active or passive activity of the reaction. Or:
(3) The stimulus-word is the object, the reaction is the activity referring to it.
(4) The stimulus-word is an activity, the reaction is its object.

[50] Let us consider the first forms: the predicative connection of noun and adjective. Two main possibilities are to be distinguished:

[51] (α) The adjective describes an essential and internally meaningful characteristic of the stimulus-image. One can call this type of predicate “internal.” It can easily be divided into two groups:

(1) Objective judgment, e.g.:

snake	poisonous
glass	fragile
mild	spring
thirst	intense
war	bloody
grandmother	old
winter	raw

These predicates describe an essential and meaningful addition to the stimulus. Their purely objective character distinguishes them from the second group:

(2) Value judgment, e.g.:

father	good
to stink	unpleasant
to ride	dangerous
mountain	beautiful
book	interesting
pupil	good
soldier	brave
wood	useful
murderer	base
water	refreshing

In these reactions the personal element is more or less prominent; but where the ego-reference is clearly expressed in the form of wish or rejection, one can speak directly of “egocentric predicates.” We do not however want to separate such reactions from value judgments as a distinct group, for reasons stated below. We also count the following as value judgments:

iron	useful metal
water	one of the most interesting chemical substances
scoundrel	disgrace

[52] Value judgments expressed in the form of an activity, e.g.:

smoke	stinks
apple	tastes nice

are best placed with the predicates.

[53] We also count as value judgments reactions in which a value is not stated but demanded, e.g.:

good	one should be
diligent	the pupil should be
to threaten	one must not

[54] Such reactions are not frequent in normal subjects; we merely mention them for the sake of completeness.

[55] (*β*) The adjective refers to an external, less significant, possibly co-existent, and perceptible characteristic of the stimulus. For this type of predicate we should like to use the term “external”:

tooth	protruding
water	wavy
tree	brown
exercise-book	blue
salt	granular
etc.	

[56] We assess the predicate-relation between adjective as stimulus-word and noun as reaction according to the principles explained above. Thus, in classifying, we evaluate *green / meadow, meadow / green*, as more or less equivalent.

[57] Aschaffenburg has with some reason considered interjections as predicates, but we have interpreted them differently (see below).

[58] A further sub-group of predicates is made up of the “relationships of noun and verb.”

[59] (α) *The subject relation*. The noun as the stimulus-word or the reaction is the subject of a definite activity:

resin	sticks
hunter	to shoot
to cook	mother

[60] *(β) The object relation*. The noun as the stimulus-word or the reaction is the object of a definite activity:

door	to open
to recruit	soldiers
to clean	brass
throat	to strangle

[61] The predicates so far discussed cannot easily be distinguished from the above-mentioned “co-ordination by example,” if the attributive part is the stimulus-word. For this diagnosis we consider decisive the subject’s evident effort to find a reaction-word (i.e., a noun) as appropriate as possible to the stimulus-word and with a general validity, as in:

to pray	pious person
to despise	wickedness
to give in	peace-loving

Thus we count *to clean / brass* as an object relation and *to clean / shining metal* as co-ordination by example.

[62] Specifications of place, time, means, and purpose are somewhat loosely connected with the group of predicates (Ranschburg’s[16] “end-defining association”).

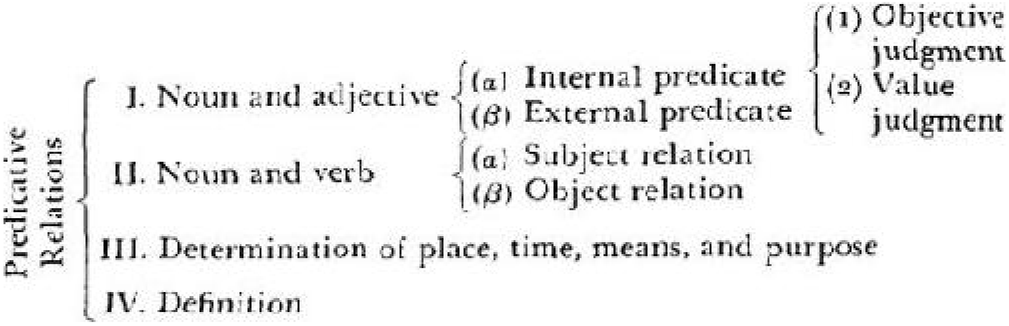
place: to go	into town
time: to eat	12 o’clock
means: to beat	with a stick

purpose: wood	for burning

[63] One can sometimes, with these reactions, be in doubt about whether perhaps they are to be interpreted as specification and therefore belong to subordinations. But in most cases the decision will be easy, so that error will not be too great. Definitions or explanations of the stimulus-word, which in general occur very rarely, have a certain connection with the group discussed above, for which reason they too have been placed in the group of predicative relations. Examples:

door	noun
blue	adjective
star	heavenly body

[64] The predicative relations are thus made up of the following groups:



Predicative Relations
- I. Noun and adjective
  - (α) Internal predicate
    - (1) Objective judgment
    - (2) Value judgment
  - (β) External predicate
- II. Noun and verb
  - (α) Subject relation
  - (β) Object relation
- III. Determination of place, time, means, and purpose
- IV. Definition

[65] (c) CAUSAL RELATIONSHIP (Münsterberg). Stimulus-word and reaction are linked by a causal connection. Examples:

pain	tears
to cut	painful

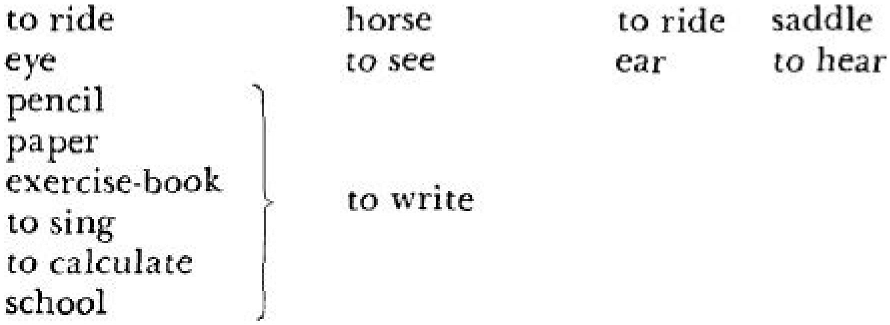
B. External Associations

[66] (a) CO-EXISTENCE. The connection of co-existence is *contiguity or simultaneity*, i.e., the link between the two concepts is not exclusively similarity or affinity but also temporal co-existence or immediate succession. Spatial co-existence is included in temporal contiguity as spatial co-existence results from succeeding sense-impressions. Examples:

ink	pen
exercise-book	knife

table	soup
Christmas	Christmas tree
Sunday	church
pupil	teacher
table	chair
lamp	family
mother	child
institution	warder

We also include here reactions like:



to ride	horse	to ride	saddle
eye	to see	ear	to hear
pencil	to write		
paper			
exercise-book			
to sing			
to calculate			
school			

The associations with *to write* are complexes of school-memories, the connection of which is conditioned by simultaneity; the other examples concern reactive images associated with the stimulus images by co-existence.

[67] (b) IDENTITY. The reaction contains no shift or development of the sense, but is a more or less synonymous expression for the stimulus-word.

[68] (α) The synonymous expression is taken from the same language as the stimulus-word. Examples:

grand	magnificent
to pay attention	to take notice (in Swiss-German usage, essentially synonyms)
to squabble	quarrel

[69] (*β*) The synonymous expression is taken from a language other than the stimulus-word, i.e., it is a *translation*. Examples:

stamp	timbre

Sunday	dimanche

[70] (c) LINGUISTIC-MOTOR FORMS. (Ziehen:[17] “Current word-compounds and associative word-complements.” Kraepelin-Aschaffenburg:[18] “Linguistic reminiscences.” Trautscholdt:[19] “Word association.”) In this sub-group of external associations we collect together all connections of images, which have been canalized through verbal practice, although logically and historically they may have a different meaning and therefore could be put into one of the types mentioned above. In dealing with *contrasts* we have already mentioned a series of reactions that we interpreted as being of such common verbal practice as to be canalized. We classify them as

[71] (α) *Canalized verbal associations*.

(1) Simple contrasts. Examples:

dark	light
sweet	sour
white	black
like	unlike

(2) Current phrases. Examples:

hunger	to suffer
house	and home[20]
of age	to come
goods	and chattels[21]
thanks	to give
gallant	to be
trials	and tribulations
world	and people
old	frail
right	to do
to come	(and) go
place	time
something	more
force	to apply
bread	to earn

head	to bow
bird	bush
water	to drink
to swim	to be able to
tram	to ride
to go	for a walk
revulsion	to arouse
cat	mouse
to break	the news

[72] (*β*) *Proverbs and quotations*. Examples:

everywhere	and nowhere
liberty	equality
everywhere	I am at home
eye	tooth
do’s	and don’ts
war	and peace
more	light[22]
meat	drink

[73] (*γ) Compound words*.

(1) The reaction-word complements the stimulus-word and forms a compound word. Examples:

table	leg
needle	case
mat	hanging[23]
piano	player
vengeance	to thirst for
frog	blood[24]
book	marker
head	scarf
tooth	ache
institute	women’s

The reaction may also be such that the stimulus-word is repeated in the reaction, e.g.:

tears	tearduct[25]
to knock	to knock at
to hear	to hear out[26]
foot	football[27]
star	starlight
sweet	sweetmeat

(2) The reaction is essentially only a grammatical variation of the stimulus-word (Wreschner:[28] "Association with inflexional form").

to die	dead
kindling	to kindle
to hammer	hammer
school	scholar
to find	found
love	to love
cab	cabby
murderer	to murder

[74] (δ) To this should be added a small group of reactions that can be termed anticipatory. Examples:

dark red	light
slow	short
grandiose	small

[75] (ε) Interjections, which only rarely occur, have been placed in the category of "linguistic-motor connections" although, as Aschaffenburg stresses, they represent a predicate. We justify our interpretation by pointing out the highly imperfect linguistic form of the reaction, which moreover contains a very strong motor component. Examples:

grand	ah!
to stink	pooh!
to love	oh!

C. Sound Reactions[29]

[76] The content of this group corresponds to Aschaffenburg’s group of “stimulus-words acting only by sound.”

[77] (a) Word completion. We interpret these words in agreement with Aschaffenburg, only including here reactions that together with the stimulus-word, form an indivisible word. Examples:

wonder	-ful
love	-ly
modest	-y
friend	-ly

We also consider addition to the stimulus-word, to form a name, as word-completion. Example:

Canter	-bury
Winter	-bourne[30]

[78] (b) Sound. The reaction is conditioned solely by the sound of the whole stimulus-word or its beginning.[31] Examples:

enchain	enchant
mercenary	merciful
intention	intestine
to roast	roast beef
humility	humidity

[79] (c) Rhyme.[32] Examples:

dream	cream
heart	smart
leave	grieve
king	ring
crank	plank

[80] To divide sounds and rhymes into “meaningful and meaningless,” as Aschaffenburg does, is not worthwhile, owing to the rarity of the “meaningless” ones. We have therefore refrained from doing this.

D. Miscellaneous

[81] This not very large group comprises reactions for which no place can be found in the rest of the schema, but which have only a very limited connection with each other.

[82] (a) INDIRECT ASSOCIATION. Aschaffenburg, as is well-known, contrasts the indirect mode of reaction with all other reactions, which he regards as "direct" ones. We have rejected this quantitatively most disproportionate contradistinction, because with uneducated subjects one can never know how many different contents of consciousness stand between stimulus-word and reaction. We cannot even *ourselves* always state how many conscious, half-conscious, or unconscious constellations affect our reactions. We will not enter here into the academic controversies about indirect association (that is, whether the intermediate link is conscious or unconscious) but confine ourselves to stating the phenomenon of the indirect mode of reaction within the framework of our cases. We call "indirect association" that mode of reaction that is intelligible only on the assumption of an intermediate link different from the stimulus-word and the reaction. We distinguish five forms:

[83] (α) Connection by common intermediate concept. Examples:

$$\underbrace{\text{white}\quad\text{far}}_{\text{snowfield}} \qquad \underbrace{\text{dozen}\quad 144}_{\text{heap}}$$

$$\underbrace{\text{false}\quad\text{blonde}}_{\text{Miss X is false and blonde}} \qquad \underbrace{\text{turbid}\quad\text{shallow}}_{\text{water}}$$

$$\underbrace{\text{repentance}\quad\text{black}}_{\text{mourning}} \qquad \underbrace{\text{red}\quad\text{scent}}_{\text{flower}}$$

$$\underbrace{\text{to close}\quad\text{round}}_{\text{to turn}} \qquad \underbrace{\text{bicycle}\quad\text{round}}_{\text{wheel}}$$

$$\underbrace{\text{to disgust}\quad\text{odourless}}_{\text{to stink}} \qquad \underbrace{\text{to walk}\quad\text{pear}}_{\text{under pear-trees}}$$

$$\underbrace{\text{fast}\quad\text{to whistle}}_{\text{locomotive}} \qquad \underbrace{\text{to turn}\quad\text{earth}}_{\text{to rotate}}$$

$$\underbrace{\text{hay}\quad\text{green}}_{\text{grass}} \qquad \underbrace{\text{rich}\quad\text{5-franc piece}}_{\text{roll of money}}$$

[84] It must be noted that in these associations the intermediate link is usually clearly conscious. Such reactions are very rare and occur almost entirely in individuals of markedly visual type.

[85] *(β) Centrifugal sound-shift* (Aschaffenburg's "paraphasic indirect association"). There is an inner reaction that is to a greater or lesser extent clear and meaningful, which, however, in the process of articulating it, is replaced by a canalized association with a similar sound. We therefore designate this group of indirect associations as "centrifugal sound-shift." Examples:[33]

decision to slide	to dress excessive
(to decide)	(overcoat)
stubborn foolish	society unit
(mulish)	(union)
to quarrel to shoot	earth house
(dispute)	(heap)
hair blue	medal fastness

(blonde)
sacrifice to castrate
(casket, sacristy)
ears typhus
(tubes)

(fastened)
love crate
(hate)
pair hoot
(boot)

[86] Cordes wants to exclude these reactions from the indirect ones, admittedly, from his point of view, with some justification. The direct inner association appears to be a genuine association and not a sound reaction; so there exists an entirely appropriate and direct intention which, however, at the moment of enunciation, is shifted towards a similarity of sound to the detriment of the meaning. Such shifts can only occur when the inner image to be expressed does not command the intensity of attention necessary to set going the appropriate speech-mechanism. Deviations into by-ways only occur when what has to be enunciated is not intense enough, i.e., it does not reach a sufficient degree of consciousness. Therefore we also assume that, in spite of correct intention, the intermediate link has remained abnormally obscure, which agrees completely with the accounts of subjects who can observe themselves. Some had no more than a feeling that they had not said the right thing, without being able to point to the intermediate link. Whether in such cases the shift towards similarity of sound occurs at the sending station or the receiving station seems to us irrelevant to the evaluation of the reaction.

[87] (γ) *Centripetal sound-shift*. The stimulus-word is internally replaced by a sound similarity, which in its turn determines the reaction. Usually the intermediate link is in that case half-conscious or unconscious. It must be noted that in all cases here classified the stimulus-word has been correctly understood, so that it is not merely a case of misunderstanding. Examples:[34]

to ride slip
(slide)
to wallow bird
(swallow)
strong sin

lazy mist
(hazy)
to rust fair
(just)
room to caw

(wrong)
malt pepper
(salt)
politics hefty
(policeman)
stroke knot
(string)
to hit to bite
(to smite)
malt vinegar
(salt)

(rook)
stroke cigar
(smoke)
to wallow throat
(swallow)
to love turtle
(dove)
pleasure tape
(measure)

[88] In our experience by far the largest number of indirect associations are shifts through sound similarity. What we have said in the preceding paragraph about the consciousness of the intermediate links also applies here. The occurrence of a sound association points to a stimulus-word with an inadequate feeling-tone.[35] Reaction to the intermediate sound-link is likewise a result of insufficient feeling-tone of the stimulus-word. In this case the sound association is, in our experience, as indistinct as the stimulus-word, and at first the subject is even unsure of the kind of stimulus-word. The reaction is innervated before the act of apperception has taken place.[36]

[89] (*δ*) *Centrifugal and centripetal shift through word-completion or linguistic-motor association*. Examples:

standard filter
(solution)
false faithfulness
(faithful)
rats poisonous
(poison)
to cook coachman
(the cook)
avarice patient
(pathological)
armlet foot

head block
(blockhead)
angel heart
(hard)
clean flea
(unclean)
painter beautiful
(painting)
lockjaw teeth
(jaw)
permanently to certify

(arm)	(deranged)
horrible grey	to roll round
(gruesome)	(roller)
look-out strike	fox finger
(lock-out)	(foxglove)

[90] *(ε) Shift by several intermediate links*. The intermediate links may be associations that are mechanical yet of high valency. The reactions in this category are very rare and are mostly of abnormal origin. All the types described above can of course be found among these reactions. Examples:

ink	acid
(red	litmus)
bird	mouse
(flutter	bat [*Fledermaus*])
lithe	big
(lice	small)
revenge	rector
(right	rectify)
tough	headache
(tooth	ache)

[91] We shall not at present look further into the theory of indirect association in acoustic-verbal experiments. For the moment let us simply say that these associations are closely connected with variations in concentration.

[92] (b) MEANINGLESS REACTIONS. In moments of emotion or embarrassment reactions are sometimes given that are not words or are not associations.

[93] We of course separate assonances as sound reactions from mere sounds. Among the non-associated words there are hardly any of inexplicable origin. They are mostly names of objects in the surroundings or of coincidental concepts that are not connected with the stimulus-word. Some nonsense reactions are perseverations of type b (see below).

[94] (c) FAILURES. The absence of a reaction we call a failure. The cause of the failure is usually emotional.

[95] (d) REPETITION OF THE STIMULUS-WORD. A very small group that could equally well be put into the category of failures! There are, however, normal individuals who cannot help quickly repeating the stimulus-word to themselves and then giving the actual reaction, a phenomenon that can be observed outside the experiment in ordinary conversation. This reaction is not included in any of the normal categories. Repeating the stimulus-word is, in any case, also an emotional phenomenon (Wreschner[37] is of the same opinion).

[96] This completes the specific classification of associations. There remain only a few general points that help to clarify the types of association.

E. The Egocentric Reaction

[97] It is striking that certain individuals tend to form ideas of reference during the experiment; that is, to give highly subjective judgments that are clearly influenced by wish or fear. Such reactions have something individually characteristic and are indicative of certain personalities.

[98] (a) DIRECT IDEAS OF REFERENCE. Examples:

grandmother	I
to dance	I don’t like
unjust	I was not
praise	for me
to calculate	I cannot

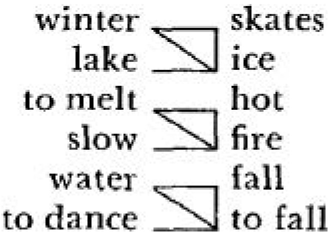
[99] (b) SUBJECTIVE VALUE JUDGMENTS. Examples:

to be lazy	pleasant
to calculate	laborious
blood	gruesome
piano	horrible
love	stupid

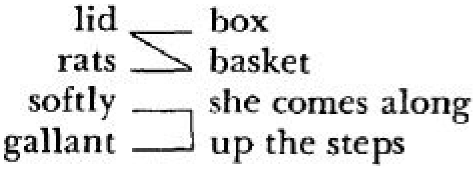
F. Perservation[38]

[100] By perseveration we understand a phenomenon[39] that consists in the fact that the preceding association conditions the next reaction. We have made it a rule to consider the effect on only the immediately following reaction. Thus we have excluded an effect that bypasses uninfluenced reactions; we prefer to consider this type of effect under the general heading of constellation. Here we do not want to be prejudiced about the nature of the phenomenon of perseveration. We must point out, however, that perseveration may be caused by psychophysical factors at present unknown as well as by specific feeling-constellations. In practice, two cases of perseveration are to be distinguished:

[101] (a) The reaction is an association to a previously used stimulus-word. Examples:



[102] (b) The reaction is not an association to a previously used stimulus-word. Examples:



[103] If at the moment of the experiment consciousness is dominated by a strongly feeling-toned complex, then a longer series of heterogeneous stimulus-words will be absorbed into the complex, each reaction being influenced by stimulus-word and complex-constellation. The more powerful the complex-constellation, the more the stimulating image is liable to assimilation (Wundt), i.e., it is not comprehended in its actual and usual sense but in the special sense adapted to the complex.

G. Repetition

[104] In each experiment the same reactions were counted; the first and second hundred of the associations in normal subjects were counted

separately. One could perhaps differentiate between repetition of content and of particular stylistic form. Since in normal subjects particular stereotype-reactions constructed with auxiliary words are extremely rare, we have decided not to count repetitions of form.

H. Linguistic Connection

[105] It is a striking fact that associations are linked to each other not only by meaning (i.e., the principles of *association*, *contiguity*, and *similarity*) but also by certain solely external motor-acoustic properties. To my knowledge Bourdon was the first to tackle this question experimentally. In his remarkable work “Recherches sur la succession des phénomènes psychologiques,” he describes investigations into the phonetic linking of association. Bourdon noted, from the top of every page in books chosen at random, the first noun, adjective, or verb. In this way he compared five hundred pairs of words. The total of phonetically similar pairs was 312, assuming a phonetic similarity if the words have one or more phonetic element in common. It must be noted, however, that Bourdon interpreted this similarity somewhat widely, e.g., *toi* and *jouer* because of the “w” sound! Bourdon examined especially the *ressemblance phonétique*, *graphique* (one or more common letters), and *syllabique* (a common syllable). He found the following comparative figures:

Ressemblance	phonétique:	0.629
“	graphique:	0.888
“	syllabique:	0.063

[106] Bourdon finds: “Il reste néanmoins vrai, que les mots s’associent entre eux plutôt par leur signification que par leur ressemblance phonétique.”

[107] In accordance with these investigations, we have assembled a group that contains external linguistic factors.

[108] (a) THE SAME GRAMMATICAL FORM. We simply counted how often the form of the word was the same in the stimulus-word as in the reaction, that is how often noun / noun, adjective / adjective occurred together. We arrived at this question because we had observed that large individual variations exist.

[109] (b) THE SAME NUMBER OF SYLLABLES. We counted how often the stimulus-word and the reaction contain the same number of syllables, with the object of finding out more about the influence of rhythm.

[110] (c) PHONETIC AGREEMENT.

(1) *Consonance*. We counted how often the first syllable of the stimulus-word and of the reaction agreed at least as regards the vowel.

(2) *Alliteration*. Here we noted how often the stimulus-word and the reaction alliterated in the first vowel or consonant.

(3) *The same ending*. Here we examined the phonetic influence of the ending of the stimulus-word on the ending of the reaction, that is, the tendency to rhyme. Here we only noted whether the final syllables tallied.

SUMMARY

[111] *A. Internal Associations*

- (a) Grouping
  - (α) Co-ordination
    - (1) By common general concept
    - (2) By similarity
    - (3) By internal relationship
    - (4) By external relationship
    - (5) By example
  - (*β*) Subordination
    - (1) Actual subordination
    - (2) Specification
  - (γ) Superordination
  - (δ) Contrast
  - (ε) Groupings of doubtful quality
- (b) Predicative relationship
    - I. Noun and adjective

- (α) Internal predicate
  - (1) Objective judgment
  - (2) Value judgment
- (*β*) External predicate

II. Noun and verb

- (α) Subject relationship
- (*β*) Object relationship

III. Determination of place, time, means, and purpose

IV. Definition or explanation

(c) Causal relationship

B. External Associations

- (a) Coexistence
- (b) Identity
- (c) Linguistic-motor forms
  - (α) Canalized verbal associations
    - (1) Simple contrasts
    - (2) Current phrases
  - (*β*) Proverbs and quotations
  - (*γ*) Compound words and word-changes
  - (δ) Anticipatory reactions
  - (ε) Interjections

C. Sound Reactions

- (a) Word-completion
- (b) Sound
- (c) Rhyme

D. Miscellaneous

- (a) Indirect associations
  - (α) Connection by common intermediate concept

    - (*β*) Centrifugal sound-shift
    - (*γ*) Centripetal sound-shift
    - (δ) Shift through word-completion or linguistic-motor form
    - (ε) Shift through several intermediate links
- (b) Meaningless reactions
- (c) Failures
- (d) Repetition of the stimulus-word

E. The Egocentric Reaction

- (a) Direct ideas of reference
- (b) Subjective value judgments

F. Perseveration

- (a) Connection with a [previous] stimulus-word
- (b) No connection with a [previous] stimulus-word

G. Repetition of the Reaction

H. Linguistic Connection

- (a) The same grammatical form
- (b) The same number of syllables
- (c) Phonetic agreement
    - (1) Consonance
    - (2) Alliteration
    - (3) The same ending

[112] We have classified our material according to the principles laid down in the schema. In order not to complicate the presentation of the results unnecessarily by a plethora of figures, the graphs published in Part Two reproduce only the figures of the main groups, allowing the extensive material to be grouped more clearly than with a detailed report of the figures for all the sub-groups. For reasons of scientific integrity we considered ourselves obliged to give an exact account of the kind of

consideration that led us to the classification of the associations in one or other main group. Also it seemed to us of general interest to state the different empirical possibilities of the associations so far as they are known to us.

[113] Thus our figures concern merely the following main groups of the schema:

I. Internal Associations
  1. Grouping
  2. Predicative relationship
  3. Causal relationship

II. External Associations
  1. Co-existence
  2. Identity
  3. Linguistic-motor forms

III. Sound Reactions
  1. Word-completion
  2. Sound
  3. Rhyme

IV. Miscellaneous
  1. Indirect associations
  2. Meaningless reactions
  3. Failures
  4. Repetition of the stimulus-word

A. Perseveration

B. The Egocentric Reaction

C. Repetition of the Reaction

D. Linguistic Connection
  1. The same grammatical form
  2. The same number of syllables
  3. Alliteration
  4. Consonance

5. The same ending

PART TWO

RESULTS OF EXPERIMENTS

A. RESULTS OBTAINED FROM INDIVIDUAL SUBJECTS

[114] Subjects reacted very differently to disturbing stimuli. Producing internal distraction was the most difficult, as already stated. It was not even possible to achieve with all educated subjects. External distraction by metronome-beats was somewhat easier. But here too great differences are apparent between individual subjects. It therefore seemed necessary to give the figures of each subject fully. Here a plethora of tables cannot be avoided. All figures are percentages.

I. EDUCATED WOMEN

Fourteen subjects with 4,046 reactions

[115] *Subject I.* In general the character of these associations [see table] is very objective and almost entirely uninfluenced by subjective constellations. In the normal state external associations prevail over internal ones. Between the first and second hundred of the normal reactions a clear difference is apparent, there being an increase of 9 per cent in the sound group. We attribute this change to a certain lassitude appearing in the reception of the second hundred, which psychologically has no more significance than a relaxation of attention.[1] There can certainly be no question here of psychological fatigue which, as Aschaffenburg has shown, brings about an increase of sound associations. The preceding psychic effort is much too slight for that. On the other hand, the relaxing of interest could very well be identified with lassitude in Kraepelin's[2] sense.

Subject 1. About 22 years of age, very intelligent

[116] The columns after those giving figures for normal conditions describe the changes of association under the influence of artificially distracted attention. From a purely dynamic point of view one could say that the "associative energy" (Ranschburg[3]) was to such an extent diverted to another area that only a fraction of it is still available for the reaction. Thus a correspondingly poor or easy (that is, strongly canalized) association is given, because the stimulation of ready and accustomed cerebral mechanisms requires a smaller amount of energy than the canalization of relatively new and unaccustomed connections. From this point of view, the increase of linguistic-motor forms by 18 per cent in internal distraction can easily be understood;[4] but to understand the origin of the numerous sound reactions in external distraction is more difficult. Aschaffenburg believes that it is possible to hold motor excitation responsible.[5] This exists in mania, exhaustion,[6] and alcoholic intoxication. But it has been proved that flight of ideas, or modes of association similar to flight of ideas, can also occur without motor excitation, e.g., in epilepsy (Heilbronner[7]), catatonia, and manic stupor.[8]

[117] In our experiment, motor excitation is as good as excluded. (The act of writing, which could be interpreted as "motor excitation," is excluded in internal distraction, the results of which coincide with those of external distraction.) Thus no relationship between sound reactions and motor excitations can be demonstrated; rather do we see the origin of sound reactions in diminished attention. Distraction has primarily an

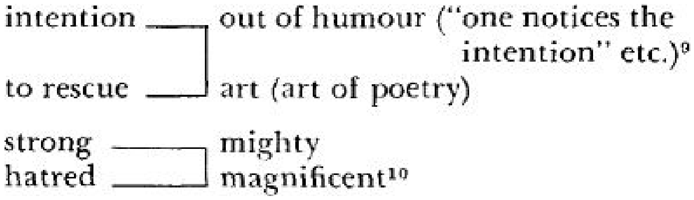
inhibiting effect on the development of internal associations (of “high valency”) and favours the formulation of external, i.e., more mechanical association-forms, hence sound reactions in large numbers. In further description of the experiment we shall have ample opportunity to point out shifts of association-form towards external, that is mechanical associations. We can say that, when the experiment was at all successful, these shifts only occasionally took place.

[118] It is striking that, in this obvious tendency towards mechanical reaction, sound reactions too were clearly favoured. But in the present state of our experience sound reactions are not mechanical, they are apparently non-canalized associations. In our interpretation, sound reactions, which are on only a slightly higher level than mere repetition of words, are the most primitive of associations by similarity. After early childhood they are no longer used but, always called up by the act of speech, they predominate as soon as a disturbance impedes the activities of the next higher levels of association (slips of the tongue or mis-hearing). They are, because of their uselessness in the normal thought-process, repressed and usually exist outside consciousness.

[119] We call the increase of linguistic-motor forms and sound reactions the blunting of the reaction. The attentive reaction, which takes place in the focus of consciousness, is not a sound reaction (unless this is expressly sought); but if one succeeds in directing attention to another activity, that is moving the psychic reaction outside the focus of consciousness, then all those associations occur that had been repressed from clearly conscious reactions. We shall deal later in detail with the significance of this hypothesis for the pathology of association.

[120] With faulty attention the stimulus-concept is not raised to a level of complete clarity or, in other words, it remains on the periphery of consciousness and is apprehended only by virtue of its external appearance as sound. The cause of these defective perceptions lies in the weakness of their emotional tone which, in its turn, is dependent on the disturbances of attention. Every process of apperception of an acoustic stimulus begins at the level of pure sound perception. From each of these levels associations can be externalized if simultaneously the speech centres are ready to discharge. That this does not normally happen is due to the inhibiting effect of directed attention, that is the raising of the stimulus-threshold for all inferior and undirected forms of association.

[121] In this case the high frequency of meaningless reactions, up to 6 per cent in external distraction, is noteworthy. They are partly due to strong perseverations, e.g.:



intention	out of humour ("one notices the intention" etc.)[9]
to rescue	art (art of poetry)
strong	mighty
hatred	magnificent[10]

and partly to distraction due to the unaccustomed noise of the metronome, e.g.:

appearance	rhythm

[122] This reaction shows to some extent how strong an effect the disturbing stimulus had on this subject. The intense lowering of attention also explains the unusually high number of sound reactions. The gradual predominance of acoustic and linguistic factors is also illustrated by the distinct rise of the figures in the columns for alliteration and consonance; there is also a definite increase in the words of the same number of syllables. The increase of perseveration during distraction is not easy to explain; perhaps it can be attributed to the lack of association caused by distraction. It seems to us worth mentioning that the external distraction in this case is a progressive one. We have used the sounds to demonstrate the progression. We divided the two experiments of external disturbance each into three parts and counted the sound associations in each part.

[123] The progression is as follows:

1st experiment:	5, 5, 7.
2nd experiment:	5, 6, 8.

[124] *Subject* 2. The general character of the associations is objective. The external associations only slightly predominate over the internal. Internal distraction seems to have had the most intense effect in this case. Sound reactions increase continuously from the first hundred on. The group of verbal associations shows, in comparison with the former case, certain differences during distraction. The agreement in grammatical form shows a distinct increase, and the agreement of number of syllables also increases generally. Consonance and alliteration, however, decrease somewhat. We do not of course know the individual causes of these differences.

[125] The relatively numerous failures are striking, most of them occurring in the first hundred. Of the four in the first hundred, three were in answer to emotionally potent stimulus-words. In the second hundred there is only one, but at the same time numerous predicates, in this case value judgments coming to the fore. This circumstance seems to indicate that failures are essentially emotional phenomena, emotional inhibitions, as it were; they disappear in the second hundred with the occurrence of facilitated and more familiar subjective judgments. As in the former case, there is a definite rise of perseveration.

[126] We should like to point out that in this case the largest number of indirect associations coincides with the smallest number of sound reactions and, conversely, the largest number of sound reactions coincided with the smallest number of indirect reactions. This correlation is, as will appear later, probably not coincidental.

[127] The nature of internal distraction (which, with this subject, was in general more successful than with the preceding one) deserves some discussion. We intentionally directed the subject's attention mainly to visual images, as in our experience these are the sensory phenomena that most frequently accompany the association experiment and in most subjects occur with great vividness. Much rarer, on the other hand, is the ability to observe and report this phenomenon accurately. For instance, the first subject gave some rather unsatisfactory information in this respect. The second subject, on the other hand, observed very acutely on the whole and was able to give clear information. The experiment is best illustrated by a few examples:

singing	opera (or concert) singing

Directly after grasping the stimulus-word, the subject sees a scene from *Tannhäuser* on a certain stage.

hearth	fire

sees a particular memory-image of a fireside scene at a house in London.

tile	roof

sees red roofs.

journey	itinerary

sees an English traveller.

apple	tree

sees a picture of Eve with the apple.

honour	sense (of)

sees the vivid memory-image of a scene from Sudermann’s *Honour*.

sail	cloth

sees a sailing-boat.

deportment	rule

sees the vivid memory-image of her younger brother at a school for dancing and deportment.

modest	-y

sees the picture of a certain young girl.

plant	kingdom

sees a certain picture-book with pictures of plants.

sign	post

sees a crossroads.

peacefully	rest peacefully

sees a certain small kitten.

music	enjoyment

sees the interior of a certain concert-hall (vivid memory-image).

[128] These examples show that the reactions are very simple, mainly linguistic-motor forms. The mental images are in a certain associative relationship with the reaction. According to the subject’s account they occur directly with the reaction, if not before it. In our view the reactions are mostly mechanical side-associations which are stimulated on the way to a higher reaction. The stimulus-image did not reach the

level of complete clarity as it lacked the necessary energy to emerge or (not to speak in Herbart’s terms) remained in the periphery of the field of consciousness, inhibited by the clear visual image. The following examples show this inhibition of the reaction, together with complete clarity of the visual image:

praise	praise for the singer

The subject sees a certain teacher, who praises her.

manners	good manners

sees the picture of a Swiss country community—of an old “custom.”

like	like will to like

sees the written sum: 2 × 2=4.

to stretch	catstretcher (*Katzenstrecker*)

sees a stretched rubber-band (*Katzenstrecker* is a popular nickname for a man from Lucerne).

tight	tight-fisted

sees a tight (narrow) lead-pipe.

stone	buck (*Stein/Bock*)

sees a collection of minerals.

change	time (*Wechsel/Zeit*)

sees a promissory note (*Wechsel*).

fashion	woman of fashion

sees an elegant youth.

dull	eyes

sees a dull, rainy landscape (constellated by the day of the experiment).

mirror	smooth

sees the window of a certain glazier’s.

forward	march

sees a copy of the *Forward* (newspaper).

down	to cut

sees a low stool in a certain sitting-room.

[129] In these reactions the connection between reaction and inner image is, as it were, completely broken. The reaction mostly comes quite mechanically from a lower level of the process of apperception, while the mental image mostly represents quite a different apperception of the stimulus-word.

[130] Conversely, the visual image may be stimulated from a lower level of apperception, as the following examples show:

number	number, quantity (*Zahl, Menge*)

sees a newly extracted tooth (*Zahn*).

to will	*you must (wollen/du musst*)

sees a woolly (*wolliges*) sheepskin.

[131] *Subject 3.* The character of the associations is objective. The external associations predominate, particularly the linguistic-motor forms. Both attempts at distraction were very successful, particularly internal distraction, which resulted in 29 per cent of sound reactions. A few reactions under internal distraction are of interest:

lid	nid (senseless rhyme)

The subject sees a beermug with a lid.

hall	throat (*Halle/Hals*)

sees a waiting-room in a certain station.

fall	staff

sees a waterfall.

stone	bone (*Stein/Bein*)

sees a picture of the little town of Stein on the Rhine.

[132] The fact that the number of internal associations remained nevertheless above the normal level in internal distraction, and in the first half of external distraction, can be attributed to the fact that the artificial lowering of attention was not uniform and continuous but decreased from time to time, whereupon normal reactions were given. The reactions obtained from the same subject in a state of great physical and mental fatigue give a more uniform picture of associative levelling-down. According to these findings, the state of fatigue has no other significance for this experiment than

a uniform lowering of attention; its repercussion on the association is in no way different from the results of the distraction experiments. Nor is a difference discernible in the finer points of individual associations—which cannot be counted or measured—except in a very few reactions, the content of which is caused by the particular constellation of fatigue. As appears from our further observations on this subject and also from Aschaffenburg's investigations, no specific change, other than the blunting of the emotional response during the state of fatigue, can be demonstrated. The blunting of the reaction in fatigue can easily be accounted for by a decrease of attention. We also have every reason to assume that the blunting of the reaction in alcoholic intoxication and manic excitation (observed by Kraepelin's school) is nothing but a symptom of disturbed attention. The connection with motor excitation suggested by Aschaffenburg is in our view merely an indirect one: the motor excitation lowers the intensity of attention and therefore brings about a blunting of associations. The disturbance of attention by motor excitation is a matter of experience and in the named conditions has long been known as "distractibility." Since attention as an affective condition is also linked to certain somatic (that is, muscular) processes, the decrease of its stability can be attributed to motor excitation. Thus Aschaffenburg is not correct when he considers motor excitation as the direct cause of the blunting of the reaction; motor excitation is absent in a whole series of abnormally low reactions. But common to all these conditions is a disturbance of attention, which is probably always the immediate cause for all association types similar to flight of ideas.[11] The origin of disturbed attention is of course different in (i.e., specific to) each single process; it can equally well be based on motor excitation or on loss or decrease of kinesthetic feelings, on raising of the muscular stimulus-threshold, on mental excitement, or on psychological split (as in our experiments).

[133] The great variability of intensity of attention makes all association experiments with alcohol and fatigue susceptible to an error extremely difficult to estimate, so that in the state of our present experience it is practically impossible to say anything positive about the extent of the disturbances of association through alcohol, etc. Judging from the percentage ratios of these fatigue experiments, the subject must have been in an absolutely psychotic state. According to Aschaffenburg's theory, a result with 5 per cent internal associations and 27 per cent sound reactions corresponds to a state of heavy intoxication or serious mania or a state of quite abnormal fatigue. The intensity of this blunting, however, can easily be explained by the fact that great but not abnormal fatigue was accompanied by marked drowsiness. The decrease of attention, with raising of external stimulus-thresholds, peculiar to this condition is, in analogy with distraction experiments, to be considered as one of the main causes of the blunting.[12] The intensity of drowsiness is an unmeasurable quantity; how much drowsiness was present in the states of fatigue examined by Aschaffenburg?

[134] Drowsiness is not merely a somatic, physiological, but also to a certain extent a psychological phenomenon, which may perhaps be described by the name "autohypnosis." It is primarily a psychological event that takes place in the area of consciousness. It is mainly stimulated by somatic sensations but can also be produced by pure suggestion. Exactly the same applies to the effect of alcohol. The

effects of alcohol may be to a large extent, particularly in the beginning of narcosis, purely suggestive; this probably accounts for the fact that the effects of alcohol on different dispositions may be quite different. Can one exclude or calculate the suggestive effects of alcohol in the alcohol experiment? In our view this is not possible. Therefore great caution is advisable in psychological alcohol experiments. Accordingly, disturbance of attention in fatigue and alcohol experiments need not always have its roots in motor excitation, but could equally well be derived from suggestion.

[135] Let us return to our experiment. The great prevalence of external association can be attributed to momentary decrease of attention. The cause of the blunt reaction can, however, lie deeper. It is not unthinkable that there are individuals who, because of a congenital or acquired anomaly, have a more superficial mode of association than others; this anomaly may possibly lie in the sphere of attention, in that fatigue appears much more quickly than in other people. The figures for the sister and mother of subject 3 are interesting in this respect as observations of family psychology. We give the tables here.

[136] *Subject 4,* about 20 years of age, is the sister of subject 3. The associations have in general an objective character; the external ones predominate considerably, especially the linguistic-motor forms. Sound reactions also are numerous, so that the character of the normal state looks like the result of a distraction experiment. In the experiment of internal distraction there is an unexpected increase of internal associations as well as a clear increase of sound reactions. The superficiality displayed in the experiment under normal conditions is in our experience abnormal, thus we must assume a disturbance of attention in this state. The subject is a definite "motor type"; from other experiments performed with the subject it becomes apparent that motor perception predominates by far over the other senses.[13] Externally too the motor disposition is shown by great vivacity of movement and a strongly developed ability for motor expression. It must here be stressed that this active motility by far exceeds the limits of conscious innervation and is expressed in motor automatisms that are innervated by unconscious psychological complexes. Among the reactions of the normal state there are two linguistic automatisms that are very probably related to an unconscious complex. This complex is closely connected with the affect concerning a past engagement. Thus we have two probable reasons for the strikingly blunt reaction-type: the strong and abnormally independent motor tendency and a partially suppressed affect. The latter probably has the most significance for the blunting.

Subjects 4 and 5. *Sister and mother of subject* 3

Sound reactions	9	14	25	3	7
Number of associations	100	100	100	100	100

[137] (It would be too much of a digression to examine the individual psychology of this case more closely. This will be done elsewhere.)

[138] The increase of internal associations during distraction experiments is a phenomenon that we find again in subjects of different character[14] who under normal conditions also show an abnormally blunt type. We know no other explanation for the improvement of reaction-type in this case than that the attention, which under normal conditions is tied to the emotional complex, is released by the conditions of the experiment (new to the subject) and can therefore be used. Nevertheless, great fluctuation of attention occurred; this is indicated by the large number of sound reactions, together with the relatively numerous internal associations.[15]

[139] A special peculiarity of this subject is the occasional occurrence of marked synesthesias (*audition colorée*), which influence the reaction. Examples under normal conditions:

to kiss (*küssen*)	yellow

ü is yellow for the subject.

misery (*Elend*)	something red

e is red.

indolent (*träge*)	blue

ä is blue.

[140] Examples from the distraction experiment:

orgy	orgy

Subject sees a yellow mass.

pious	blessed

sees something yellow.

[141] Strangely enough, the subject [3], who has the same reaction-type as subject 4, is also a definite “motor type” and also has very vivid synesthesias, which, as it happens, did not appear in the reactions.

[142] The following phenomena from the distraction experiment are worth mentioning:

stork	-’s leg

Subject sees a church-tower.

to hinder	hammer-let (Hamlet)

sees a brake.

fall	bone (*Fall -z bein*, paper-knife)

sees a high wall from which one could fall.

red	wine

sees a red sphere.

barrel	-ter (*Fass -ter* [*Vater?*])

sees a certain cellar.

[143] From the subject’s account, the visual image fills consciousness completely and exclusively, the verbal reaction being given almost involuntarily and touching consciousness only quite superficially. The above examples show clearly and repeatedly the purely mechanical character of the verbal reaction.

[144] *Subject* 5 is the mother of subjects 3 and 4. Quantitatively the reaction-type shows much similarity with that of subjects 3 and 4. The objective character of the reactions is qualitatively also very similar. Particularly prominent in these three people are the linguistic-motor forms. Characteristic of this family type are sound

reactions under normal conditions, which distinguishes this type from others. For comparison, we give the main figures for these subjects under normal conditions:

	Internal Associations	External Associations	Sound Reactions
Mother	29.5%	62.0%	5.0%
Elder daughter	27.5%	67.0%	3.5%
Younger daughter	13.0%	71.5%	11.5%

[145] We draw attention to the increasing degree of blunting in the younger daughter. If the figures were all from the same individual one could believe that it is a distraction experiment. Perhaps this relationship is accidental but perhaps it has deeper psychological reasons. We refer to a similar observation reported below. Ranschburg[16] found 11.8 per cent more internal associations in old than in young subjects.

[146] *Subject 6.* Such external associations as are usually found in the normal state predominate. The second hundred shows a slight increase of external associations and a clear increase of sound reactions. The quality of association deviates considerably from the types so far reported, reactions of strongly subjective character occurring with this subject. They are in part highly charged value judgments, e.g.:

pupil	boring
father	good
book	interesting
school	beautiful
frog	nice
piano	horrible

[147] On the other hand, it is the predicates that designate properties of things that are to a greater or lesser extent evident to the senses. In the second hundred an increase of groupings from 9 to 14 and a decrease of predicative relations from 32 to 14 can be noticed; accordingly the quality of reactions is altered in so far as they assume a noticeably more objective character with a tendency to irrelevant clichés. The decrease of predicative relations is due to the shifting of subjective value judgments into the background. Thus the more subtle quality of the reactions also shows a markedly fading interest. The relaxation of attention is shown very clearly in the decrease of egocentric reactions from 10 to 4. From this result the distraction experiments must be considered a failure. Objectively this is also shown by the subject’s being unable simultaneously to follow the beat of the metronome and to react; either the motion of writing ceased at the moment of reaction or the reaction-time lengthened to the next pause in the beat, when the reaction was given with renewed attention. The only disturbing influence was the perseveration phenomenon, which significantly only occurred with external distraction.

Subject 6. About 35 years of age, intelligent, very well read, poetic talent

External associations	53	63	56	56	54
Sound reactions	4	7	–	8	4
Number of associations	100	100	50	50	50

[148] The almost undiminished personal interest at the time of external distraction is well illustrated by the relatively large number of egocentric reactions. We will refrain from judging how far the relatively strong verbal connection by consonance under normal conditions is caused by the constellations of active poetic application. Many reactions of this subject betray a strong visual predisposition. From the subject’s own account every stimulus-concept presents itself as a quite definite picture. The entirely individual character of the reactions distinguishes this subject from others and differentiates her from the subjects so far discussed. It is interesting to learn whether this type is accidental or whether it is of familial origin. Happily we are in the position of being able to some extent to answer this question.

[149] *Subject* 7. The number of internal associations considerably predominates over the external ones. The number of predicative relations is extremely great. Most of these consist of subjective value judgments, some of which are highly charged, e.g.:

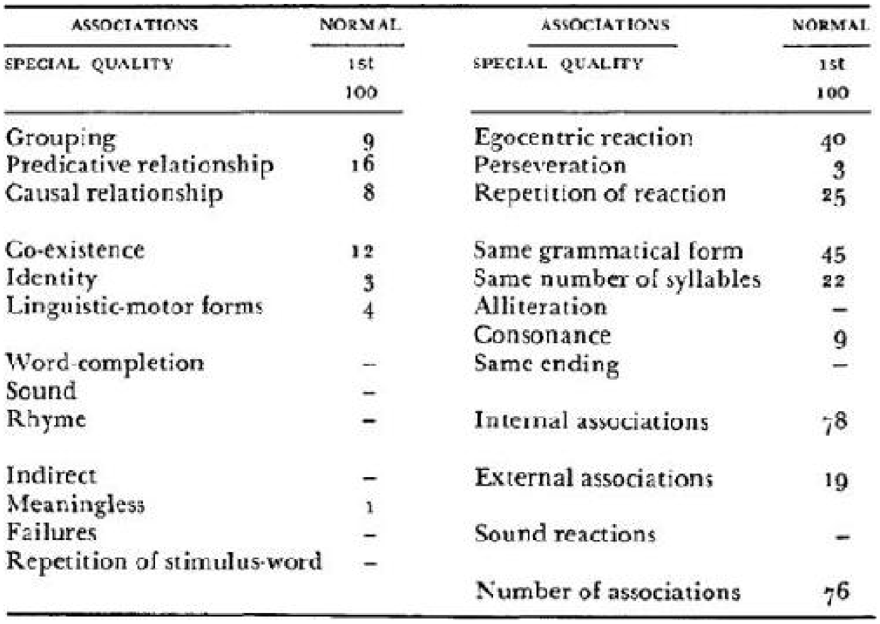
to cook	laborious
water	wonderful
star	magnificent
to ride	dangerous
prison	horrible

About 40 per cent of the reactions betray an egocentric direct wish or a defence.

[150] *Subject 8*. The internal associations are more numerous than the external. This subject also showed a very subjective reaction-type, which appears particularly in the large number of predicative relations and especially in the numerous subjective value judgments. The number of egocentric reactions too is rather high.

[151] From these figures and from the individual quality of the reactions, a clear familial relation emerges. Thus we can conclude with some probability that the subjective reaction-type of subject 6 is based not on coincidence but on familial disposition. It will be of interest to consider the quantitive aspects within this family; particularly whether, in the case of the youngest member, we can prove an analogous proportion in respect to the blunting phenomenon found in the family of subjects 3, 4, and 5. For this purpose we again collate the main figures of our subjects in a normal state.

Subject 7. The mother of subject 6, over 50 years of age, educated



ASSOCIATIONS	NORMAL	ASSOCIATIONS	NORMAL

Mother	75%	19%	0	40%
Elder daughter	56%	39%	1%	15%
Younger daughter	35%	58%	5.5%	7%

[152] These figures show a complete analogy to what we find in subjects 3, 4, and 5. This too looks like a distraction experiment which goes as far as the reversal of the relation of internal to external associations. There is a corresponding increase of sound associations as well as a decrease of egocentric reactions which, as was shown in subject 6, express the degree of personal interest. This strange analogy between

the two family types does appear to be more than mere coincidence. Unfortunately our material is not sufficient to elucidate these observations. A final statement and interpretation of this apparent fact must for the moment await an experiment at present being carried out based on specially collected material.

Subject 8. The elder sister of subject 6, about 39 years of age, educated

		Number of associations	78

[153] The reaction-type of the last three subjects is characteristic and widespread. What distinguish it from other less definite types are the numerous predicates, among which is a considerable number of subjective value judgments. We call this type the predicate type. The following three subjects are further examples of it.

[154] *Subject 9.* The predominance of predicative relationships is clear in all phases of the experiment. Internal distraction could not be carried out as the subject was not capable of dividing her attention. The experiment of external distraction failed completely as the subject, exactly like subject 6, could not carry out two actions at the same time and therefore behaved exactly like subject 6. Only in the larger numbers of verbal connection by number of syllables, alliteration, and consonance may a certain shift of reaction towards the mechanical side be noticed.

[155] Three of the four failures under normal conditions are associated with emotionally charged stimulus-words (*unjust*, *rich*, *stupid*).

[156] The average predominance of internal association over external is noteworthy in an educated subject. The reaction-type is a mixed one and does not by any means show the strongly subjective character of subjects 6, 7, and 8.

[157] *Subject 10.* The predicative relationships are on the average many times as numerous as the number of groupings. With reference to the failure in distraction, the

same must be stated as for subjects 6 and 9. The reaction-type is, particularly in the first hundred under normal conditions, a somewhat subjective one, which incidentally is also expressed by the 9 per cent of egocentric reactions. Perseverations occur solely with distraction. As in subject 9, there is an increase in the number of syllables and consonances, which perhaps may be interpreted as slight disassociation. The large number of failures in all phases of the experiment is striking. Of the 14 failures under normal conditions, 10 coincide with emotionally charged stimulus-words (*must, unjust, violence, to threaten, to suffer*, etc); in another two failures the subjective emotional charge of the stimulus-word is only probable. It must here be said that the subject is slightly hysterical in so far as she has somnambulant dreams. We attribute the large number of failures to this abnormality. We shall present the proof of this hypothesis in a publication about association anomalies in hysteria which will appear later.[17]

[158] *Subject 11* is an outstanding predicate type of subjective character with numerous value judgments. A marked slackening in the second hundred is striking; this may be attributed to obvious and objectively established boredom. Thus the second hundred does not correspond to normal conditions but rather to a distraction experiment. Nevertheless, if we compare the reaction-type of this subject with that of the daughter, subject 10, we find the same phenomenon as before, that is that the daughter's reaction-type is a blunter one than that of the mother.

	Internal Association	External Association
Mother	51%	43.5%
Daughter	36%	53.5%

[159] We take this opportunity to repeat that in spite of this agreement the phenomenon may be pure coincidence and therefore urgently requires retesting.

[160] We also give the figures for three further subjects. *Subject 12*, a North German lady. The large number of current phrases is particularly striking. Internal distraction failed. External distraction shows a definite disturbance of attention. The reaction type is objective.

[161] *Subject 13*. Very diffident, hence the large number of repetitions of the stimulus-word. Only distraction by metronome-beat of 100 was to any degree successful. The writing movements were, in accordance with what has been said before, very awkward.

[162] *Subject 14*. We give figures for this subject only for the sake of completeness. The reaction-type is an objective one. Internal distraction was only partially successful. Its effect is uncertain as, because of the omission of the second hundred of normal reactions, we have no information on the degree of variation in normal people. The second hundred could not be obtained for external reasons.

Summary of the Group of Educated Women

[163] Unfortunately the material collected in this group is quantitatively somewhat uneven. On the other hand, the linguistic background is very similar, only one out of the fourteen subjects coming from North Germany and all the others being Swiss, whose colloquial language is the Swiss dialect. Their level of education is in general very high, two of the subjects having University education. Six subjects know one or two foreign languages. Ten subjects are relatively well read. Distraction experiments were carried out with ten subjects; of these in five cases external and internal distraction, in two cases only internal and in three cases only external was carried out. External distraction was definitely successful in four cases, internal in three. One case of internal and one of external distraction were partially successful.

[164] Distraction failed in four cases, of which three are definite predicate types. (All predicate types who took part in the distraction experiments at all showed a much smaller distraction phenomenon than the other subjects.) Of the six subjects over 30 years of age, three showed an average predominance of internal association over external; of the eight subjects under 30 years of age, only one subject showed a predominance of internal association over external.

II. EDUCATED MEN

Nine subjects with 3,793 *associations*

[165] *Subject* 15. Reactions were obtained from this subject in four different states of disturbed attention: in the states of internal and external distraction, fatigue, and morning drowsiness on waking. The reaction-type is a very blunt one, as the ratio between internal and external associations shows, 15 : 78 and 29 : 65. The reactions show a very objective, almost entirely verbal character. The distraction experiments do not have much influence on the ratio between internal and external associations; on the other hand, the progression of sound reactions illustrates the increasing disturbance of attention, which reaches its maximum in the second external distraction experiment. Fatigue, which admittedly in this case was not very great,

produced no change in type. The state of drowsiness caused a disturbance of attention which far surpassed the effect of the second external distraction. The subject experiences intense morning drowsiness after mental work at night, and it is difficult to wake him up completely. These reactions were obtained while the subject lay in bed and was only partially awake. The subject had been warned beforehand. The two experiments were carried out on two different days with an interval of about a week. As the figures show, the type is an excessively blunt one. Sound reactions are extraordinarily numerous, particularly the rhymes. The figures for verbal connection are very high. This reaction-type shows the reaction to the most primitive linguistic mechanisms in, as it were, complete isolation. Fatigue is entirely excluded in these experiments; there is merely a decrease of active attention normal towards the end of sleep. As far as we know, attention is completely extinguished in sleep. If one succeeded in obtaining a reaction from a sleeping (but not somnambulant) subject, sound reactions would be the only result. In our view absolute undeviating attention directed inwards would have the same result. We are in the happy position of being able to report on a case that proves this to be so.

Subject 15.[*] *28 years of age, intelligent, very well educated*

[166] The subject N. was deeply disturbed by violent affects. Outwardly the main symptom was an almost complete lack of ability to concentrate. She kept the cause of her affects secret. In the experiment, to which she submitted out of scientific

interest, she produced, apart from a few inexplicable (senseless) reactions, mainly sound and rhyme reactions.

[167] We should like to compare this case with a distraction experiment spread out over several days. Attention is completely bound up with the inner, emotionally charged complex,[18] from which she cannot detach herself for comparatively unimportant incidents. Her attention is thus abnormally low for anything that does not concern the complex. We cannot of course judge how far this withdrawal is conscious. As the subject related, at the beginning of the experiment certain strongly charged ideas belonging to the complex were in her mind, which she constantly tried to suppress, because she feared they might betray themselves in the reaction. From the second third of the experiment onwards, only the feeling-tone of the complex persisted in consciousness, without these accompanying vivid ideas. The next things to occur to the subject were only sounds. The stimulus-words only made an impact by the sound and never by the sense.

[168] These observations prove most clearly the dependence of sound reactions, particularly those of the blunt reaction type, on disturbance of attention. Now, how can we explain the normally blunt reaction-type? The subject was psychologically trained and took the greatest interest in the experiment. The blunt reaction-type would seem to be connected with the fact that many educated subjects regard the experiment as simply verbal; they see the experiment against a verbal background and thus they try to respond to the stimulus-word by the first word to occur, without considering the meaning of the stimulus-word. They do so because it seems obvious to them that an isolated stimulus-word cannot have any special significance. This is how we explain the great predominance of verbal and sound associations. All those subjects who let themselves be influenced by the meaning rather than by the mere word tend to form internal associations. The meaning that different people give to the stimulus-word will vary. In our experience there are two main types of people: (1) The subject tries to do justice to the meaning as objectively as possible; therefore in his reaction he produces some general or special association of objective significance; the reaction is usually a co-ordinating relationship. (2) The subject endeavours to designate in a telling way the object named by the stimulus-word, which he vividly pictures. To state something about the stimulus-word, the subject uses the predicate. The reaction is therefore in most cases a predicative relationship.

[169] On these grounds the blunt reaction-type of certain educated subjects should not be considered as the result of some disturbance of attention but as an “attitude phenomenon” (Bleuler). By the term “attitude phenomenon” we understand with Bleuler the emergence of an apparently abnormal reaction type through intentional preference for a certain mode of reaction. The mode is not, however, as must be stressed, chosen arbitrarily but motivated by the particular psychology of the subject. The more intense the attitude to the sound-effect of the stimulus-word, the blunter

the reaction-type must become, for, by specially directed attention, the subject will stress and put in the foreground all the more primitive associations that are repressed in the normal act of speech. Thus a very paradoxical picture can be created by the numerical presentation of the results of the experiment; we can understand it only on the grounds we have given. The following case will illustrate this.

[170] *Subject 16*. Here we find again a strikingly blunt reaction-type in the experiment under normal conditions, which is illustrated particularly by the large number of sound reactions. The blunting is considerably increased in the experiment with internal distraction; on the other hand, in the experiment with external distraction a striking “improvement” of reaction appears, the number of internal associations far exceeding that for the experiment under normal conditions. The “improvement” is quite clearly demonstrated by the decrease and eventual disappearance of the sound reactions.

[171] This particular result is unique in our experiments and needs discussion. We have already mentioned the present subject in discussing subject 4 of the group of educated women, who presented a similar picture; we then assumed that suppressed affect was the cause of the blunt reaction-type. In this connection the very satisfying findings presented above in the discussion of subject 15 of the group of educated men should also be mentioned. The recent very strong affect that took complete possession of this subject was the direct cause of the preponderance of sound reactions. The affect in this case was repressed, inasmuch as it did not manifest itself directly in the reaction but only indirectly through a splitting of attention. One must assume a similar psychological situation also for subject 4 of the group of educated women and so explain the blunt type. The fact that subject 4 of the group of educated women and subject 16 in the group of educated men are of the same type is perhaps fortuitous.

[172] Affect is probably completely out of the question in subject 16. We must therefore look for another cause for the blunt type: we find it in the attitude phenomenon. Subject 16 is thoroughly trained psychologically and at the same time has extraordinary powers of concentration. The subject had from the first directed his attention towards the sound of the stimulus-word and consequently reproduced the first association to occur. These can only be primitive verbal connections and sounds, if our presuppositions on associations closest to the perception of the stimulus-word are at all correct. In this way the abnormally blunt type in the experiment under normal conditions can be explained without difficulty.

Subject 16. 47 years of age, intelligent, very well educated

[173] The blunting increases in the internal distraction experiments. The subject carried out this experiment in a model way; concentration on the D (distraction) phenomenon was excellent, as was the reporting of it. We therefore have no reason, in this case, not to assume distraction of attention. Thus the blunt type of reaction in this experiment is to be attributed to decrease of attention. It springs from a root different from the one in the experiment under normal conditions; consequently it is not an attitude-phenomenon.

[174] External distraction has a disturbing effect on the attention of most subjects and therefore causes blunting. In the present case the effect appears to be the opposite. The normal state of this case is characterized by the attitude phenomenon; attention is directed exclusively to the linguistic aspect. Now this attitude is disturbed by external distraction and the subject now has a different relation to the stimulus-word; i.e., the exclusive observation of the sound is disturbed and thus the production of the nearest primitive association is prevented. If the associations that are always repressed under normal conditions sink back into repression, then the next ones to follow must be the associations conditioned by the meaning of the stimulus-word; i.e., the number of sound-reactions must fall and the number of internal associations must rise. That is the case here.

[175] The figures for fatigue show a remarkable agreement with those for internal distraction. Judging from external demeanour one could diagnose quite severe

fatigue. This was actually not the case. The fatigue was by no means abnormally severe but merely a relatively slight evening fatigue which, according to the subject's account, did not noticeably influence the reaction.

[176] Here again we have an attitude phenomenon and met a disturbance of attention. That the attitude was apparently more intense in this state can perhaps be deduced from the fact that the subject, who is a "motor" type, is when slightly fatigued liable to motor excitation. Speech motility of course also plays a part in general motor excitation, the speech mechanism very easily responding to the appropriate stimulus. This circumstance may have coincided in this case with the special attitude, resulting in a greater number of purely mechanical connections.

[177] As can be expected of such a type, the personal and subjective elements in the quality of the reactions gradually recede, with few exceptions.

[178] *Subject 17*. The reaction-type is fairly blunt. In internal associations predicates are particularly prominent and have an almost exclusively objective character. As the number of egocentric reactions shows, relatively few subjective aspects appear. But as predicate types always present emotionally charged constellations, there is here, too, an emotionally charged complex noticeable in the reactions. The experiment was carried out on a very hot day: among the repetitions, there is *snow* twice and *to sweat* twice. Apart from these there are the following perseverations:

Subject 17. *About 26 years of age, intelligent*

5. to dance	to sweat

[179] *Subject 18*. The subject, a doctor, 36 years old, felt indisposed during the experiment under normal conditions. The experiment with external distraction could not be carried out because of illness. The hundred associations carried out in “fatigue” were obtained after an eventful night without sleep.

[180] Internal distraction and fatigue show a striking agreement: a most definite decrease of internal associations, increase in external and particularly in sound associations and word-completion, an increase in the “same number of syllables” group, while the figures for the same grammatical form remained on the whole uninfluenced. In the first hundred in the experiment under normal conditions, there is a preponderance of internal over external associations (47 : 43); in the second hundred the relationship is reversed (30 : 59). The constant increase of word-completion and sound reactions in the experiment with internal distraction is nicely demonstrated if they are counted separately in each third of the hundred associations. We find:

1st third: 2 word-completions, 6 sound reactions
2nd third: 5 word-completions, 7 sound reactions
3rd third: 9 word-completions, 9 sound reactions

[181] The predicates are already on the decrease in the second hundred of the experiment under normal conditions, even more so with internal distraction; they disappear completely in fatigue. Rhymes do not become prominent till the fatigue experiment; we only find two under internal distraction and none in the experiment under normal conditions.

CONSTELLATIONS AND COMPLEXES

[182] In subject 18 we meet a relatively large number of associations that can be explained only by reference to individual experiences from the recent past or present, e.g., *ring / garden*: at the time of the experiment a gold ring had been found in the garden of the establishment where the subject worked and its owner had not been found.

Subject 18. 36 years of age

[183] Or *clothes / Stapfer*. A patient by the name of Stapfer, who was in the care of this particular colleague, worried him greatly because, for example, he ordered clothes and afterwards always found so much to criticize in them that he finally would not wear the garment; there then followed much unpleasantness with the tailor and other suppliers.

[184] Or *pencil / Kohinoor*. Our colleague had at the time of the experiment just learned about the useful properties of this brand of pencil.

[185] Or *murderer / Kaufmann*. Our colleague had at this time to give an opinion of a defendant by the name of Kaufmann, who had committed murder when intoxicated.

[186] This type of association is caused by definite constellations (Ziehen), referring to relatively new, subjective, possibly emotionally charged experiences.[19]

[187] In some subjects (e.g., subjects 25 and 27, uneducated women) we find none at all or only very few. Such individuals react throughout entirely objectively and betray practically nothing personal in the associations. For example, they associate *river / stream; school-boy / girl; table / floor; lamp / oil; mountain / valley; to kiss / to laugh; to plunder / to catch; to beat / to bite; prison / punishment;* etc.

[188] Admittedly other subjects also make objective associations; from time to time there are among them associations which, in spite of their objectivity, allow

conclusions about the subject, although they do not in the least betray his inner personality. It will not be difficult, for instance, to recognize the male nurse from the following compilation of associations (subject 35, uneducated men): *to fetch / to run; to stink / foul air; to inform / report; prison / asylum; ill / melancholic; errand / to run; freedom / convalescence; consciousness / to drink* or *sobriety*, etc.

[189] Nevertheless the constellation plays only a very indirect role in these associations.

[190] Then there are subjects—that is to say, associations—in which not the momentary constellations but the individual experiences predominate (e.g., subject 19, educated men):

Lake (See)	*Untersee* (the subject had from time to time been to that lake)
father	*grandfather* (the subject still has a grandfather)
mountain	*Glärnisch* (the subject had been to that mountain once, without the journey having had any special meaning for him)
hair	*hair-lotion* (the subject occasionally prepares a hair-lotion in the dispensary for the patients)
sweet (Süss)	*Süsskind*[20] (proper name of someone not at all important to the subject)
potato	*tobacco fields* (fortuitous memory of a journey from Basel to Heidelberg)
coffee	*Brazil* (the subject had several times drunk Brazilian coffee)

[191] These are mainly subjective reminiscences. Going a step further, we encounter the constellations *sensu strictiori* that we first mentioned when discussing subject 18 in the group of educated men. Individuals with many constellations usually also have many reminiscences (e.g., subjects 18 and 19, educated men).

[192] A separate group of constellations arises in some individuals through the influence of the immediate surroundings in which the experiment is carried out. The reaction-words *carpet, flowers, ink-pot, calendar, books, pen-holder, landscape, telephone, wallpaper, curtain, mirror, sofa*, etc., usually refer to objects in the consulting-room even if they are associated with a quite suitable stimulus-word. The subject does not necessarily need to see the objects but only to know that they are in the room (see subject 25, uneducated women).

[193] From pathology—in normal, imbecilic, hysterical stupidity—quite pronounced cases of this type of association are known to us.[21]

[194] If the stimulus-word evokes a subjective emotionally stressed image with the corresponding reaction then we get a special type of constellation-association—namely, the egocentric (as in Part I). In subject 4 [educated women] we find only a few, e.g., *piano / horrible* (the subject had to put up with the tinkling of her not exactly musical neighbour). Or *to be lazy / glorious;* the egocentricity of this reaction is readily understandable for a busy person who is looking forward to approaching holidays.

[195] In some cases an egocentric reaction can be directly replaced by a missing reaction, a failure (see definition in Part I). It is not true that there is no reaction at all, but through a conscious or unconscious inhibition the reaction-word does not get as far as being spoken. This is probably not the origin of all failures, but certainly of the majority.

[196] Girls, for example, fail with stimulus-words bordering on sexual themes, e.g., *to love, to kiss, to stroke, to choose, fidelity*, etc. Often it does not actually come to a "failure" but the association *to love / brother* takes a relatively long reaction-time, so that the experimenter after some experience soon discovers who is concealed behind the innocent-seeming brother.

[197] The associations *wedding / unhappiness, to kiss / never*, and others of subject 19, educated men, have an analogous significance; the subject was at that time in a state of "suspense and anxious longing."[22]

[198] Now it is possible that an emotionally charged complex of ideas becomes so predominant in an individual and has such a profound influence that it forms a large number of constellations, failures, and reactions with long reaction-time, all referring to this complex of ideas. Subjects 19, 20, 21, and 22 of the group of educated men will give us an opportunity to return to this special form of constellation; the majority of complexes operative in the association experiments relate to direct or transposed sexuality. In the work on the associations of hysterics we shall return to the effect of the complex.

[199] In subject 18 of this group, we can show, besides many reminiscences, fifteen constellations in the first hundred under normal conditions, four in the second hundred, one under internal distraction, and twelve in fatigue. In the experiment under normal conditions it is often the names of definite people, e.g., *clothes / Stapfer; keeper / Baum* (Baum is the name of a particular keeper); *tooth (Zahn) / Göschenen* (the subject had a discussion in Göschenen about the poet Zahn).

[200] The constellation also expresses itself through proper names with subject 19 of this group. When the constellations are on the increase owing to fatigue (e.g., subject 18, educated men) they nearly always consist of the reaction in the form of a proper name; the reaction is associated to the stimulus-word also through similarity of

sound (e.g., the internal connection of *clothes / Stapfer* in contrast to the purely sound connection *Stahl* [*steel*] */ Stapfer*).

[201] *Subject 19*. Physician, 25 years old. Fatigue was defined as the condition of the subject at ten o’clock in the evening after a full working day.

[202] The ratio between internal and external associations is not unambiguous in the different experiments. The maximum of external associations, 61 per cent, is found in fatigue but it is only a little larger than the figure in the first hundred under normal conditions, 57 per cent. This maximum of external associations corresponds to a minimum of sound reactions.

[203] Internal distraction proves stronger than external. The first fifty associations with external distraction were obtained with a metronome beat of 60, the second fifty with a beat of 100, and the last eighty-five associations with a beat of 108. Internal distraction corresponds to a maximum in the columns for sound reactions, same number of syllables, same grammatical form, alliteration, and consonance.

[204] In external distraction the sound associations decrease progressively and the indirect associations rise progressively, a proportion that we shall often meet again in distraction experiments. In the last third of the experiments with internal distraction the subject became uninterested, as if hypnoidal. At this point the number and intensity of visual images decreased, while the sound associations increased, as follows:

1st third: 3 sound associations
2nd third: 6 sound associations
3rd third: 18 sound associations

Subject 19. Physician, 25 *years of age*

[205] The number of perseverations fluctuates within the normal limits. We give as example:

The origin of this perseveration is obvious. *Fidel* is on the one hand a sound association of *fidèle*, the latter being a translation of "faithful." Here is another example:

fruit	Thurgau
false	Falk (falcon)

The family gets its fruit from Thurgau, from a Mr. Falk. Falk is a sound association to the second stimulus-word and in coexistence with the first. And, for instance,

Stern is the name of a young Jewish lady. Isaac, the son of Abraham, is a fairly frequent though not a current association. The association to Stern is internal.

Alt	Uchtspringe
Freiheit (freedom)	at the Altmann

Alt is, as is well known, the director in Uchtspringe. Freiheit is the name of a peak near the Altmann, in the Säntis area.[23] Thus we have here a perseveration of purely external nature.

[206] With internal distraction we find in our subject an example of persistent perseveration of visual images appearing with the reaction. The reaction-words are associated with the stimulus-word only by sound:

		Visual image
malt (*Malz*)	painter (*Maler*)	brewery
omnipotence (*Allmacht*)	Halma [a game]	a barrel of malt
spring (*Quelle*)	the house at the fountain	in a district where there was always a strong smell of malt, the subject had often seen mal carts in his youth

[207] After the first reaction, *malt / painter (Maler*), the subject could not repeat his own reaction-word; he had forgotten it. While forming associations his attention was directed much more to visual associations than to verbal reaction. For similar reasons we find this forgetting of the stimulus or reaction-word much more frequently in pathological cases of emotional stupidity and hysteria.

COMPLEX-PHENOMENA AND THE UNCONSCIOUS

[208] Going through the associations of our subject, only the experienced observer would notice the complex-phenomena which are very important in normal subjects as a basis of comparison with pathological ones, where complexes play a large role. Unfortunately reaction-times were not taken in the material of subject 19 now being used.

[209] The material used here is derived not only from experiments on subject 19 used previously in our work but also from some earlier ones. What we recorded was the following (starred: not used in this work):

On Sept. 17	78 associations without fatigue*
Dec. 27	78 associations without fatigue*
Dec. 27	a further 78 associations in fatigue
Feb. 22 (foll. year)	156 associations in fatigue*
Aug. 19	200 associations without fatigue
Aug. 19	100 associations with internal distraction
Aug. 25	185 associations with

	external distraction

[210] The subject had, during the time of the experiments, formed an attachment to a young woman. To make the experiments understandable it must also be mentioned that the young man had not yet outgrown adolescent internal conflict, and as he had had a strict Christian upbringing, his inclination for a Jewish girl worried him a great deal. Let us call her Alice Stern: we shall be keeping as near the truth as is necessary for the experiment. In the experiment on September 17 we find the following complex-constellations:

1. wedding	misfortune
2. come	come with me
3. to suffer	oh heavens—yes!
4. misery	who has not spent miserable nights?
5. to kiss	never
6. game	sweet games will I play with you
7. sofa	a particular chaise-longue (in the drawing-room of the young woman)
8. to love	is useless
9. fidelity	sweetheart
10. wreath	bridal wreath (thought of with the appropriate melody)[24]
11. hope	Thou shalt in life (quotation, continuing “be with us loving and comforting”)

[211] Numbers 1, 5, and 8 are disguised wishes, although the external form is a negation. Numbers 2, 4, 6, 10, and 11 are quotations or lines from songs; number 6 is the continuation of number 2, a quotation from the *Erlkönig*.

[212] It is most noteworthy that in the other seventy-eight associations only one other quotation occurs, namely

to be compelled	“no man can be compelled to be compelled”[25]

and quotations are very rare in the associations of this subject. Thus the complex makes use of a mode of reaction that is not usual in this subject: in fact, it is characteristic that the subject had only (to his shame, it might be said) salvaged from the *Erlkönig* this small fragment, “Come with me, sweet games will I play with you” into conscious memory.[26] Of the *Jungfernkranz* (bridal wreath), too, he only knows the very small fragment of the text, “We shall weave a bridal wreath for you,” although he knows the whole tune. We shall return later, in the work on hysterical associations, to the frequently quite unconscious and automatic emergence of tunes and quotations, often only in fragments. (Cf. a similar phenomenon in subject 26, uneducated women.)

[213] In the first experiment of December 27 the subject formed among others these associations:

1. it	“It, it, it, and it. It is a hard end”
2. you	yes … I
3. parting	is painful
4. star (*Stern*)	hm!
5. game	amusement (with long reaction-time)
6. heart	(the subject asks to be allowed not to say the reaction; it would have been Stern)

[214] The associations 1, 2, 3, 4, and 6 are self-explanatory after what has already been said. In 5 the long reaction-time, occurring suddenly, is suspicious.

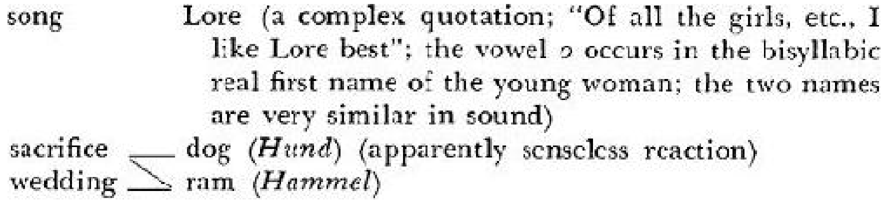
[215] From the experiment of December 27 in fatigue, the following associations taken in their context are striking:

1. to kiss	yesterday
2. to love	yesterday
3. already (*schon*)	yesterday (the stimulus-word *tears [Tränen]* had preceded it; the subject thought he heard *schön* [beautiful]; we might have here a perseveration of the umlaut)
4. miracle	yesterday
5. to pray	yesterday

[216] The reaction-times were usually quite short. The subject had the feeling that the reactions had taken him unawares. In the whole experiment no other reaction was repeated, except *kraut* twice (with *potato* and *sauer*). In the other experiments, too, repetitions are rare.

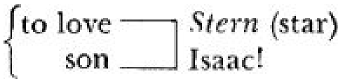
[217] All the stimulus-words quoted belong to those with a close connection with the complex “Stern.” The stimulus-word *already (schon*) was understood as *beautiful (schön*), preceded by *tears (Tränen*). As we recall, examples 4 and 5 especially were reactions at that time most closely connected with the complex (religion!). *To kiss* and *yesterday* are not to be regarded as a recollection; their relationship was not of this nature. It cannot be said with any certainty whether the unconscious had permitted itself to use the reaction *gestern (yesterday*) symbolically on account of its second syllable, or whether this word has any connection with the fact that this experiment took place immediately after the Christmas holidays, during which the subject had been tremendously pleased by a small present from the young woman. But the fact that this word, and this word only, is so often repeated in the experiment as a reaction to the complex stimulus-words is most striking. It replaces the quotations of the previous experiment (in this experiment there is not a single one).

[218] The experiment of February 22 of the following year took place in fatigue. The following associations are worthy of mention:



song	Lore (a complex quotation; "Of all the girls, etc., I like Lore best"; the vowel ɔ occurs in the bisyllabic real first name of the young woman; the two names are very similar in sound)
sacrifice	dog (*Hund*) (apparently senseless reaction)
wedding	ram (*Hammel*)

—a perseveration of the reaction. In the combination *sacrifice / ram / wedding*, the complex certainly played a part; in this connection the perseveration in the experiment under normal conditions of August 19 is comprehensible:



to love	*Stern* (star)
son	Isaac!

[219] One association is senseless: *rich / yesterday;* probably *yesterday* occurs as an association produced in embarrassment which has become stereotyped; it occurs again in this experiment in *a people / yesterday*. Here too one can only conjecture; perhaps the concept "Jews" is the link. The association *game / parents* can be explained as indirect; the link, which was unconscious, is the quotation: "My dear child, come away with me, beautiful games, etc." the significance of which we learned above. The following associations also occur:

inn	the Star (*Stern;* the subject was aware of the complex here)	to part	hurt
		to cut	hurts
		to stroke	hurts
to kiss	together	to beat	hurts
to love	roses	to sing	hurts

[220] The first four associations belong to the complex, the following are probably only stereotyped repetitions of "parting hurts." Here too the repetition must still be considered as the effect of the complex.

[221] Otherwise only a few repetitions occur.

[222] In the distraction experiments there is no manifestation of the complex.

[223] *Subject 20.* In the second half of the experiment under normal conditions,

(1) the internal associations increase from 49 per cent to 54 per cent, while the external decrease;

(2) the sound reactions increase from 2 per cent to 6 per cent;

(3) the perseverations from 6 per cent to 8 per cent;

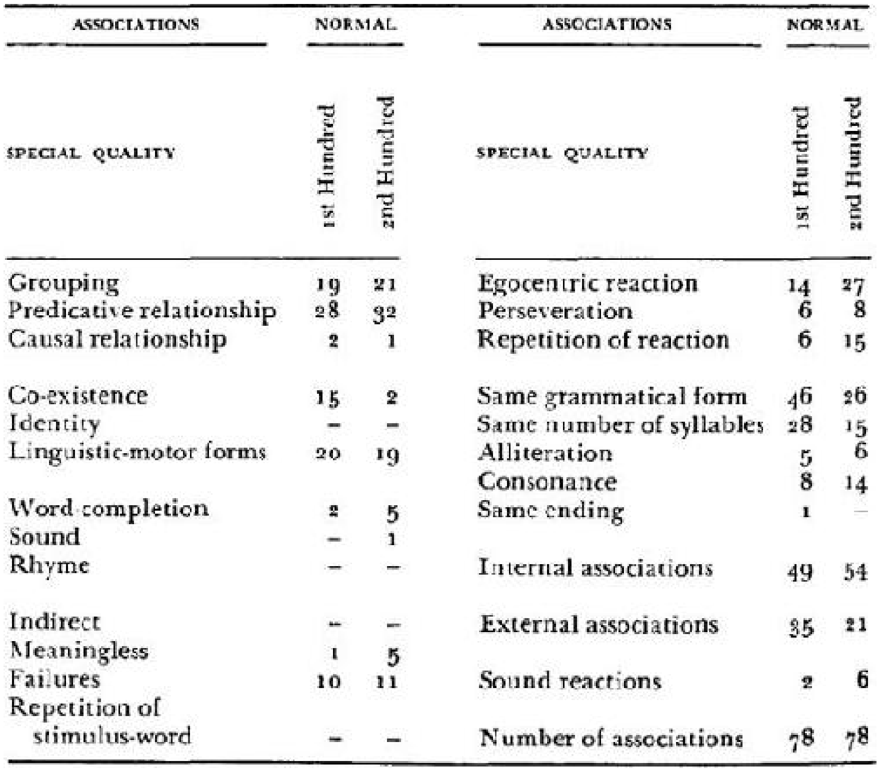
(4) the egocentric reactions from 14 per cent to 27 per cent;

(5) the constellations from 56 per cent to 73 per cent;

(6) the repetitions from 6 per cent to 15 per cent.

[224] The following are well above average in number: Internal associations,
perseverations,
egocentric associations,
failures,
and the predicates (v. infra, the section on averages).

Subject 20. Science teacher, 25 *years of age*



ASSOCIATIONS	NORMAL		ASSOCIATIONS	NORMAL	
SPECIAL QUALITY	1st Hundred	2nd Hundred	SPECIAL QUALITY	1st Hundred	2nd Hundred
Grouping	19	21	Egocentric reaction	14	27
Predicative relationship	28	32	Perseveration	6	8
Causal relationship	2	1	Repetition of reaction	6	15
Co-existence	15	2	Same grammatical form	46	26
Identity	–	–	Same number of syllables	28	15
Linguistic-motor forms	20	19	Alliteration	5	6
			Consonance	8	14
Word completion	2	5	Same ending	1	—
Sound	–	1			
Rhyme	–	–	Internal associations	49	54
Indirect	–	–	External associations	35	21
Meaningless	1	5			
Failures	10	11	Sound reactions	2	6
Repetition of stimulus-word	–	–	Number of associations	78	78

[225] The linguistic-motor reactions are roughly equal in both halves; there are no indirect associations.

[226] The figures given above indicate that the subject reacts very subjectively and that by analogy a complex can be presumed in addition. The high number of constellations (56 per cent and 73 per cent) makes this very probable. On analysis, they predominantly refer to *school* and *bride*. The subject is an enthusiastic teacher; on the other hand the complex *bride, wedding,* etc., plays a preponderant role in his reactions, particularly in the second half, where the subjective phenomena are in any case more numerous.

[227] In the first half:

26 per cent of the reactions refer to school, 21 per cent to the bride complex.

In the second half:

21 per cent of the reactions refer to school, 24 per cent to the bride complex.

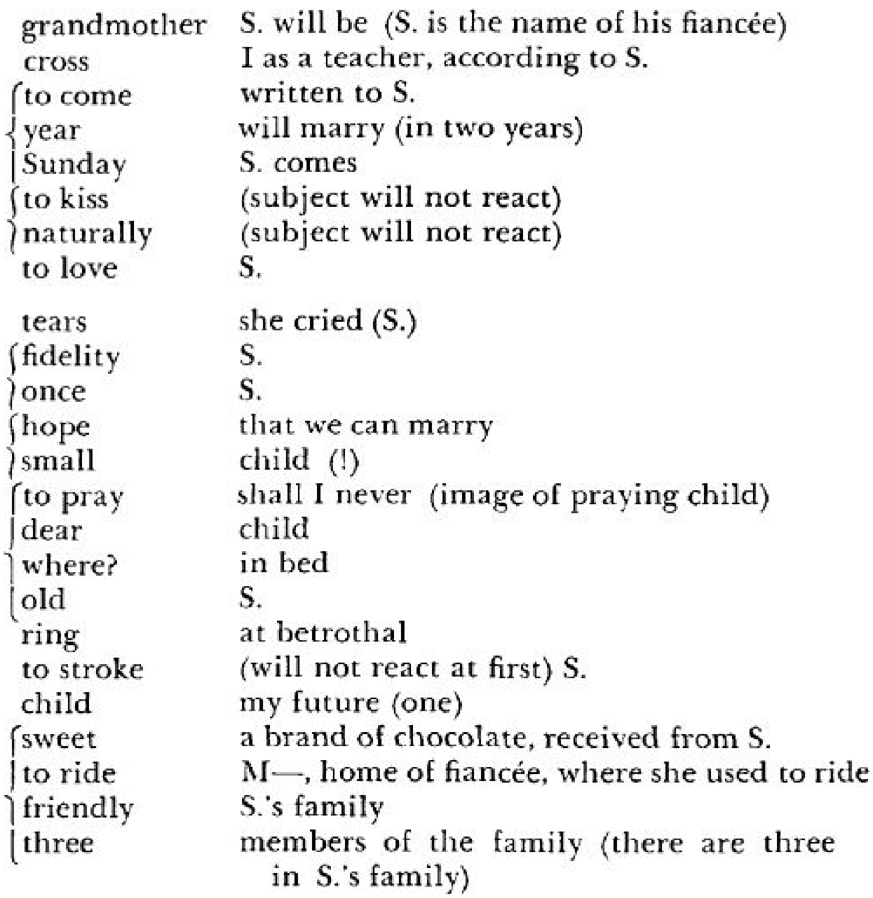
[228] In addition, two to three failures in the first half and the majority of failures in the second half refer to the bride complex, e.g., the failures after the stimulus-words *to stroke, ill, to suffer, to kiss*.

[229] Apart from this, the complex is expressed less deviously than in the preceding subject; it is less repressed and does not fall back on song-quotations as with the former subject. Incidentally, *school* and *bride* are closely connected in subject 20, as he cherished the dream that he would soon be married and his wife would assume an important position in the institute.

[230] Among the thirteen repetitions in the first half, the name of the institute occurs four times, an important event at the school twice, the name of the fiancée three times. In the second half, the name of the fiancée occurs seven times in the reactions, the word *child* twice, at which the subject thought of his future parenthood. The other repetitions mostly concern school matters; three times the subject was annoyed at the seemingly nonsensical stimulus-word and each time reacted angrily with "Rubbish!"

[231] The perseverations, with two exceptions, concern school and family affairs.

[232] Finally, a few examples of these complex-associations:



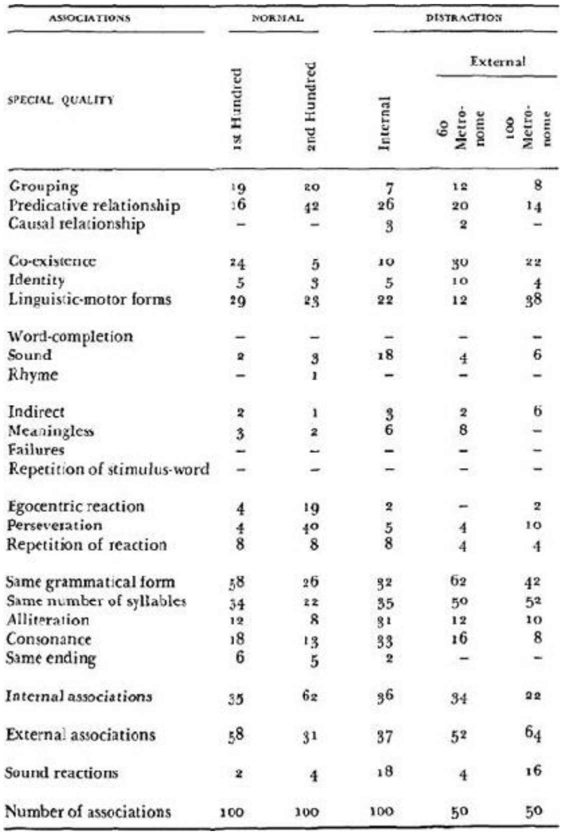
grandmother	S. will be (S. is the name of his fiancée)
cross	I as a teacher, according to S.
⎧to come	written to S.
⎨year	will marry (in two years)
⎩Sunday	S. comes
⎧to kiss	(subject will not react)
⎩naturally	(subject will not react)
to love	S.
tears	she cried (S.)
⎧fidelity	S.
⎩once	S.
⎧hope	that we can marry
⎩small	child (!)
⎧to pray	shall I never (image of praying child)
⎪dear	child
⎨where?	in bed
⎩old	S.
ring	at betrothal
to stroke	(will not react at first) S.
child	my future (one)
⎧sweet	a brand of chocolate, received from S.
⎪to ride	M—, home of fiancée, where she used to ride
⎨friendly	S.'s family
⎩three	members of the family (there are three in S.'s family)

[233] The bracketed stimulus-words followed each other immediately in the experiment.

[234] With the increase of the subjective emotional content in the course of the experiment the value of the individual reactions also increases, as the figures show.

[235] *Subject* 21.[27] In the second hundred reactions of the experiment under normal conditions we find a maximum of co-ordinations, predicative relations, of internal associations generally, while the external associations diminish greatly. This maximum also covers the perseverations and egocentric associations.

Subject 21. Physician, 23 *years of age*



ASSOCIATIONS	NORMAL		DISTRACTION		
				External	
SPECIAL QUALITY	1st Hundred	2nd Hundred	Internal	60 Metronome	100 Metronome
Grouping	19	20	7	12	8
Predicative relationship	16	42	26	20	14
Causal relationship	–	–	3	2	–
Co-existence	24	5	10	30	22
Identity	5	3	5	10	4
Linguistic-motor forms	29	23	22	12	38
Word-completion	–	–	–	–	–
Sound	2	3	18	4	6
Rhyme	–	1	–	–	–
Indirect	2	1	3	2	6
Meaningless	3	2	6	8	–
Failures	–	–	–	–	–
Repetition of stimulus-word	–	–	–	–	–

External associations	58	31	37	52	64
Sound reactions	2	4	18	4	16
Number of associations	100	100	100	50	50

[236] In comparison with the average figures for educated men, the predicates in the second hundred, the total of internal associations generally, as well as the perseverations and egocentric reactions, are high above average, in the following ratio:

Predicates	42 : 19.7
Internal associations generally	62 : 36.7
Perseverations	40 : 2.4
Egocentric reactions	19 : 2.8

while the remaining figures deviate little from the average. With the fifteenth stimulus-word of the second hundred (*to kiss*) the complex-reactions begin, at first still interspersed with others; then the complex persists through twenty-six associations, then again with interruptions, disappearing again towards the end of the second hundred. Thus altogether we find a maximum of 50 per cent of complex-constellations in the second hundred of the experiment under normal conditions; 13 per cent in the first hundred; under internal distraction 5, under external 8. We have already found an increase of complex-reactions in the second hundred of the experiment under normal conditions with subject 20, educated men. The appearance of the complex, in this case conjured up by an appropriate stimulus-word *to kiss*, causes a big increase of internal associations, probably due to the intense stimulation of attention. That the manifestation of the complex corresponds to an increase of internal associations is a proof that our classification is to some extent valid and natural. The stronger the emotional stress of the stimulus-word is for the individual and the more attention is devoted to that stimulus-word, the more the number of internal associations rises. This phenomenon is the exact opposite of the distraction phenomenon. Attention is improved because of the invasion of an emotional complex, which absorbs the whole personality, because the attention is directed more to the significance of the stimulus-word.

[237] If attention is distracted from the experiment not by external distraction but by an emotionally charged complex, as for example in subject 18 quoted above (experiment after sleepless, eventful night) who was under the influence of strong emotion, then we see the opposite of the phenomena that we have just described in subject 21: internal associations decrease and the result is very similar to an experiment with internal or external distraction.

[238] Thus in the second hundred, strong emotionally charged complexes were more manifest and perseverated more; there is, in contrast to the phenomenon usually appearing in the second hundred, an increase instead of a decrease of internal association, predicates, etc. That there are, among the stimulus-words of the second hundred, in the experiment under normal conditions, rather more words that stimulate slightly emotionally charged ideas is of no consequence in this case or in that of subject 20 of this group, because the complex manifests itself even with stimulus-words that are seemingly of no special significance.

[239] It is noteworthy that in complex-constellations the reactions readily come in the form of sentences, in other associations only rarely.

[240] In distraction the complex no longer plays a role. In internal distraction we find a maximum of sound reactions (18), which is somewhat above the average for educated men.

[241] In the first group of external distraction experiments we find in the reactions a maximum of “same grammatical form” (62) and “same number of syllables” (50); in internal distraction, on the other hand, a maximum of alliterations (31) and consonance (33 per cent).

[242] *Subject 22*.

Internal associations. Decrease in the second hundred of the experiment under normal conditions, which is much more marked under distraction.

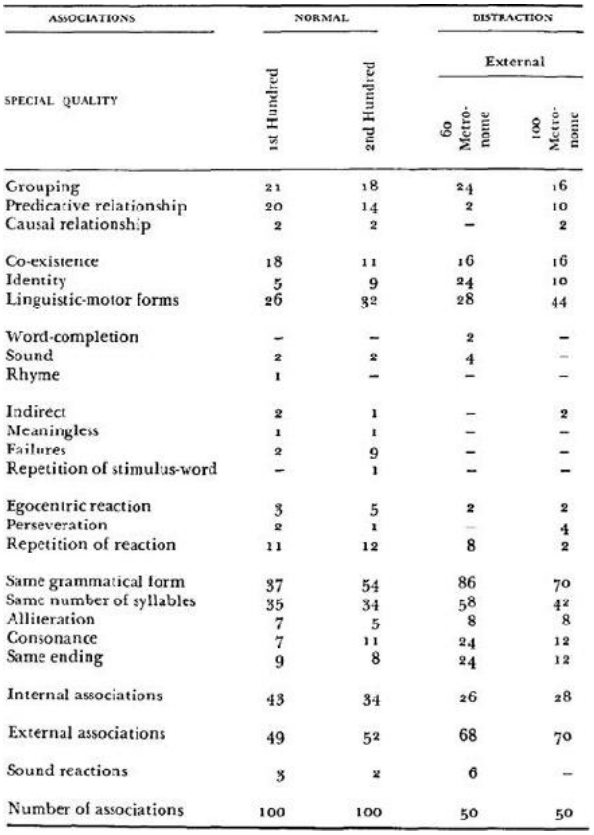
External associations. Increase in the second hundred and under distraction. Most predicates decrease mainly in the second hundred, as do the constellations.

Linguistic-motor forms. Increase in the second hundred and in the second half of the distraction experiments; there we find a maximum of linguistic-motor forms.

Repetitions and failures. Most frequent in the second hundred of the experiment under normal conditions; in addition, under distraction there is an increase of same grammatical form, same number of syllables, alliteration, consonance, and same ending.

[243] In the second part of the distraction experiments there is an improvement of reaction (perhaps due to getting used to distraction); slight increase of internal associations and predicates, absence of sound reactions, slight increase of constellations, slight decrease of same grammatical form and of same number of syllables, consonance, and same ending; on the other hand, increase of linguistic-motor forms and thereby of external associations. Perseverations also occur here most frequently.

Subject 22. Chemist, about, 24 years of age



ASSOCIATIONS	NORMAL		DISTRACTION	
			External	
SPECIAL QUALITY	1st Hundred	2nd Hundred	60 Metronome	100 Metronome

Egocentric reaction	3	5	2	2
Perseveration	2	1	–	4
Repetition of reaction	11	12	8	2
Same grammatical form	37	54	86	70
Same number of syllables	35	34	58	42
Alliteration	7	5	8	8
Consonance	7	11	24	12
Same ending	9	8	24	12
Internal associations	43	34	26	28
External associations	49	52	68	70
Sound reactions	3	2	6	–
Number of associations	100	100	50	50

[244] The constellations are nearly all conditioned by love or the subject’s profession. There occur:

In the 1st hundred, normal conditions	44%
In the 2nd hundred, normal conditions	20%
In the 1st half of distraction	6%

In the 2nd half of distraction	14%

[245] The following perseverations, caused by a complex, are worthy of note:

1.	lady	of the heart
	shoulder	blade
	to twine	entwine (the subject pictures an erotic situation)
2.	square (*Platz*)	Town Hall
	lawn	*Platz* (this perseveration is not fortuitous either; a definite story, with erotic significance for the subject, is linked with the Town Hall square)

[246] Failures appear in two forms in subject 22: sometimes the verbal reaction fails and in its place there is a vivid visual image, for example, or a vivid emotionally charged sensation, which the subject subsequently describes.

[247] In the other group there are inhibitions because certain erotic memories emerge.

[248] Under distraction no failures occur. The egocentric reactions predominate in the experiment under normal conditions and refer mainly to erotic subjects.

[249] Of the repeated reaction-words only *bright*, *good*, and *beautiful* occur more than twice.

[250] *The complex*. The erotic complex rules a large number of reactions—a total of thirty in the experiment under normal conditions, and ten in the second half under distraction (15 per cent under normal conditions and 20 per cent in the second half under distraction are demonstrable). In the first half, where distraction is more complete, we find none. The complex is hardly suppressed; on the contrary, it is manifest.

[251] The progressive decrease of sound reactions in the course of the external distraction experiments and the increase of indirect associations is in keeping with our assumptions. (See “Averages.”)

[252] *Subject* 23. The figures show a very slight distraction-phenomenon. The proportion of internal and external associations changes very little in the distraction experiment, so that the variation in the results of the two experiments in fatigue are greater than between normal conditions and distraction. On the other hand the sound associations increase under distraction, as with subject 19 of this group; in both there are fewer sound reactions in fatigue.

[253] The associations in fatigue were obtained from both subjects under very similar conditions (normal fatigue after a doctor’s working day, 10 o’clock in the evening), while a sleepless night, with heavy psychic demands due to emotion, preceded the associations in fatigue of subject 18 of this group. Here we find in fatigue an increase of sound reactions.

[254] The negligible difference caused by distraction may in subject 23 be connected with the fact that the number of internal associations is already fairly low in the experiment under normal conditions (24, that is 26 per cent instead of 36.7 per cent, as in the average of educated men) and the number of external ones fairly high (72, that is 69 per cent instead of 52.7 per cent, the average of educated men). The number of internal associations in the experiment under normal conditions is roughly the same as the average number of internal associations under distraction (in educated men).

[255] The effect of fatigue is visible in the first fatigue experiment but not in the second.

[256] The figures for alliteration and consonance in distraction have perceptibly risen, as with subjects 18 and 22 of this group.

[257] The number of repetitions is throughout above the mean; there are relatively many words that are repeated twice but only very few that are often repeated. In almost all experiments we find *pleasant*, *unpleasant*, *gladly*, *unwillingly*, *friendly*, and similar words among the repetitions. We shall not examine the individual cases of repetition and perseveration any further here, because they do not point towards such obviously emotionally charged ideas as in the earlier cases; nevertheless, these do not entirely lack this background.

Number of associations	100	100	100	50	50	156	155

[258] The constellations are few and far between. Here too we find a decrease of sound associations at the same time as an increase of indirect associations in the second part of external distraction.

GENERAL REMARKS ON THE GROUP OF EDUCATED MEN

[259] We had at our disposal nine subjects, whose ages ranged from 23 to 47, with altogether 3,793 associations. With five subjects, the experiments were carried out with internal as well as external distraction; in one case only with internal distraction, and in one case only with external distraction; in two cases no distraction experiment took place. With five subjects, associations in fatigue were also worked over, with one subject associations in a state of drowsiness. All the subjects in this group have had academic education. Six of them are physicians, one a medical student, one a grammar-school teacher, and one a chemist. All are German-Swiss.

[260] Only one subject is of the predicative type (No. 17). Unfortunately we could not carry out a distraction experiment on him.

[261] The experiment with internal distraction was successful in four cases; the sharp increase of sound reactions is most characteristic, the decrease of internal with the increase of external associations is less prominent. In one case (16) the result was unexpected, in another (23) there was no definite result; the subject had a minimum

of internal and a maximum of external associations already in the experiment under normal conditions.

[262] External distraction was clearly successful in two cases; in two cases the success was very moderate, in one case (23), on the other hand, no definite effect was noted. In general the effect of internal distraction is more intense than that of external. These particular subjects always succeeded in fulfilling the experimental conditions for internal distraction.

[263] The associations obtained in fatigue give a result similar to that of distraction in three out of the five cases. In one case (18) it is particularly clear; but it is possible that perhaps fatigue was not, or not solely, responsible for that, as the subject had had a particularly exciting experience during the sleepless night and probably was still very much distracted by it during the experiment.

[264] The association experiment in drowsiness with subject 15 also gave a result similar to that of a distraction experiment.

[265] In four subjects (19, 20, 21, 22) we find in the course of the experiment, particularly under normal conditions, extensive complex phenomena. In the first three (19, 20, 21), we see that the internal associations increase in the second hundred of the experiment under normal conditions and the external associations decrease, i.e., the opposite of what one would expect. At the same time we find an increase in the complex-constellations. In the distraction experiment the complex-constellations usually decrease or disappear.

[266] The subject need not be conscious of the complex phenomena and they often do not emerge till the association results are statistically worked over and grouped. Thus, lesser complex-phenomena may also be found in subjects without this distinct complex-type, e.g., in subject 18 (see below, the examples of association-types given in detail) or in subject 16, where in plotting a curve of reaction-times, several emotionally charged associations from long ago appeared. Practically every lengthening of reaction-time, even within quite normal limits (of which the subject is not aware), signifies, as far as we know at present, that the particular stimulus-word has touched upon a feeling-toned complex. We shall describe these findings in a later communication.

III. UNEDUCATED WOMEN

Eight subjects with 2,400 associations[28]

[267] *Subject 24*. The associations of this subject are given in detail among the examples of association types (see below). As in uneducated subjects generally, we find relatively more internal reactions and fewer linguistic-motor forms than in

educated subjects. The increase of internal associations, particularly of predicates in the second hundred of the experiment under normal conditions, may be attributed to the predominance of personal participation after the subject had grown used to the experiment. We have already met this phenomenon several times.

Subject 24. Nurse, 18 years of age, Swiss, secondary-school education

[268] Although distraction was successful, it was not exactly striking. External associations increased, sound and indirect associations, which are quite absent under normal conditions, occurred. Strikingly enough, perseverations are also more numerous.

[269] Distraction had little effect, for several reasons: the subject has relatively many predicative reactions without actually belonging to the predicative type; the latter, however, is distinguished by a weaker distraction-phenomenon. The subject often found it difficult to divide her attention and to react simultaneously to the metronome and the stimulus-word. Secondly, the experiments with uneducated women gave us the impression that these found dividing their attention more difficult than did educated subjects. They are usually completely absorbed by the experiment and work with quite concentrated attention. The stronger the means of distraction, the more desperate their effort. Thirdly, we know that in this case the experiment had a very strong psychic effect on the subject. Emotions relating to the subject's complex, some of which were only recently assuaged, came to the fore and strongly affected

the reaction. The experiment was a revival of a complex that had become somewhat latent. That is why we find a large number of obvious complex-reactions even in the distraction experiment, which as a rule is rarely the case.

[270] The complex-phenomena require a short explanatory case-history. The subject had a country background and became a nurse at seventeen, after brooding at home for a year upon the unhappy termination of a love-affair. Her irascible father did not want to know anything of the relationship and once there was a scene during which he cursed her because she had dared to contradict him. Facial burns, accompanied by great terror, and a tedious illness had revived this psychic pain through brooding shortly before the associations were taken. The association experiment gave rise to a further exacerbation of this unhappy memory; the effect persisted for some time, a proof of how intense a reagent these experiments are, particularly with uneducated subjects, and with how strong an affinity an emotionally charged complex attracts and uses for itself as large a number of stimulus-words or stimulus-concepts as possible. Now, six months after the experiment, the subject has a more objective attitude towards the complex which, however, still strongly affects her. While then, in her explanation, she emphasized that she was bound to be unhappy because of her father’s curse, she now no longer conceals the deeper erotic connections when she has to comment on her reactions. It is striking how vividly she still remembers every reaction she then gave.

[271] The number of demonstrable complex-constellations is (in percentages):

	1st half	*2nd half*
Under normal conditions	15	21
With distraction	16	14

[272] As already stated, we only rarely find complex-constellations under distraction and hardly ever to this extent. Naturally this interferes severely with distraction. The maximum of complex-constellations in the second hundred under normal conditions is, as in other cases, explicable by a difference of attitude, through becoming familiar with the experiment.

[273] Perhaps in order to be less obvious, perhaps because it takes less effort, the complex expresses intimate feelings by clichés such as quotations, words of songs, titles of stories, and such like. Quotations are frequently masks. We use them in everyday life, too, in this sense. One sings certain songs in certain moods, often because one does not want to express the thoughts that underlie the moods; so they become masked. Or the song, the quotation, is used to exaggerate a rudimentary feeling, perhaps to awake a spark of feeling by this exaggeration; one need only think of patriotic songs and poems to celebrate birthdays, special occasions, and festivals. Examples:

come	to the meadow

The quotation comes from the story of the lazy school-boy who wants to tempt the hard-working one to play truant; the lazy one later becomes a tramp, the steady, hard-working school-boy a respected teacher. For the subject the quotation has a quite different background. In any case it is not without reason that the meadow occurs twice as a reaction in the experiment under normal conditions. In the orchard of her parents’ house there is a beautiful tree surrounded by grass; here she often used to dream and, as she watched trains coming and going on the nearby railway-line, she would make fantastic travel plans. After the unhappy end of her love-affair the subject had a wish-fulfilment dream: she was lying next to her beloved in the grass. She still thinks of this dream with pleasure. To the stimulus-word *dream* she immediately reacts with *pleasure* and her eyes shine at the memory of that wish-dream. Further quotations:

at home	it’s nice

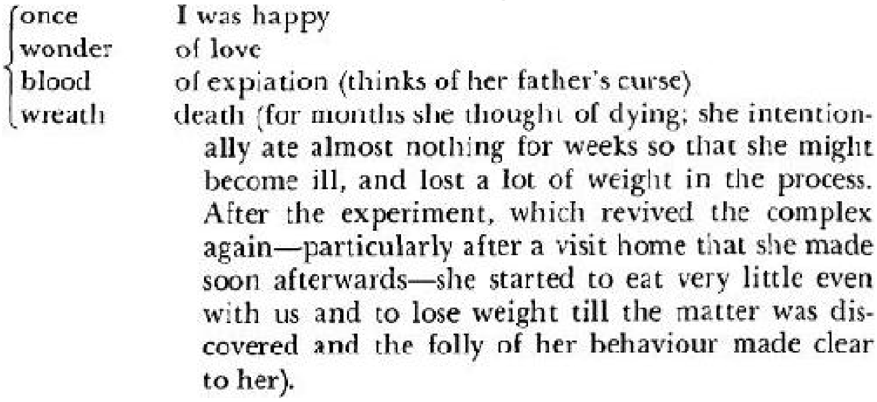
refers to a song, the meaning of which is clear. Further:

once	I was happy

The subject once heard a wicked, stupid catatonic woman sing:

> Once I was so happy,
> But now no more,
> Love, the magician, deceived me full sore.

In the next three associations she remains caught up in the complex:



once	I was happy
wonder	of love
blood	of expiation (thinks of her father’s curse)
wreath	death (for months she thought of dying; she intentionally ate almost nothing for weeks so that she might become ill, and lost a lot of weight in the process. After the experiment, which revived the complex again—particularly after a visit home that she made soon afterwards—she started to eat very little even with us and to lose weight till the matter was discovered and the folly of her behaviour made clear to her).

[274] On other occasions the subject quotes the titles of stories, the content of which refers to her complex, e.g.:

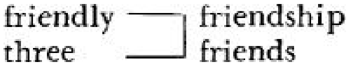
seven	brothers

“The Seven Brothers” is the title of a story in which devoted brother-love is rewarded.[29] The association immediately following is:

ill	my brother

[275] The quotations, six in all, occur only in the experiment under normal conditions (as with subject 19, educated men) and all evidently refer to the complex.

[276] We have already quoted two examples where the complex entraps the subject in an idea. Others occur, e.g., this perseveration:



friendly	friendship
three	friends

The subject has an intense need for friendship; but there have always been disappointments—her best friend married another girl.

[277] Another example, from the experiment under distraction:

meadow	the orchard
to bring	the apples

[278] We have here a direct perseveration not of the reaction but of the image of the underlying situation. We shall in the course of the work include these forms also in the concept of perseveration. The connection between meadow and orchard is clear to us at once from what has been said above (meadow!). The “apples” of course come from the same orchard.

[279] Of the four (8 per cent) perseverations in the distraction experiment, there is only one that probably refers to the complex.

[280] *Repetitions*. In the experiment under normal conditions, seven reaction-words occur several times (two to five times); at least thirteen of these seventeen words belong to the complex. In the distraction experiments (one hundred reactions) there are altogether eight reaction-words that occur several times (two to three times). The ratio expressed as a percentage is also roughly the same as under normal conditions (2 × 8 = 16). Of those, four (8 per cent) definitely refer to the complex.

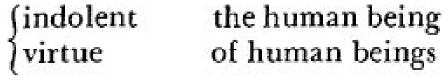
[281] It is striking how often *human being* appears as a reaction; eight times in three hundred associations (normal conditions and distraction). There are seven reactions that certainly belong to the complex. *Human being* sometimes refers to a quite definite person, sometimes to the subject herself.

[282] Similarly we find the reaction *the person* several times used as a general term, with quite concrete meaning in reference to the complex, e.g.:

propriety	the person
bad	the person

[283] The subject is thinking of a quite definite person, her friend, who plays an important part in the complex. She is not morally faultless—has, for instance, an illegitimate child. By the reaction *human being* she often means this same friend,

who in her more frivolous life had more luck in love than the more serious subject, e.g.:

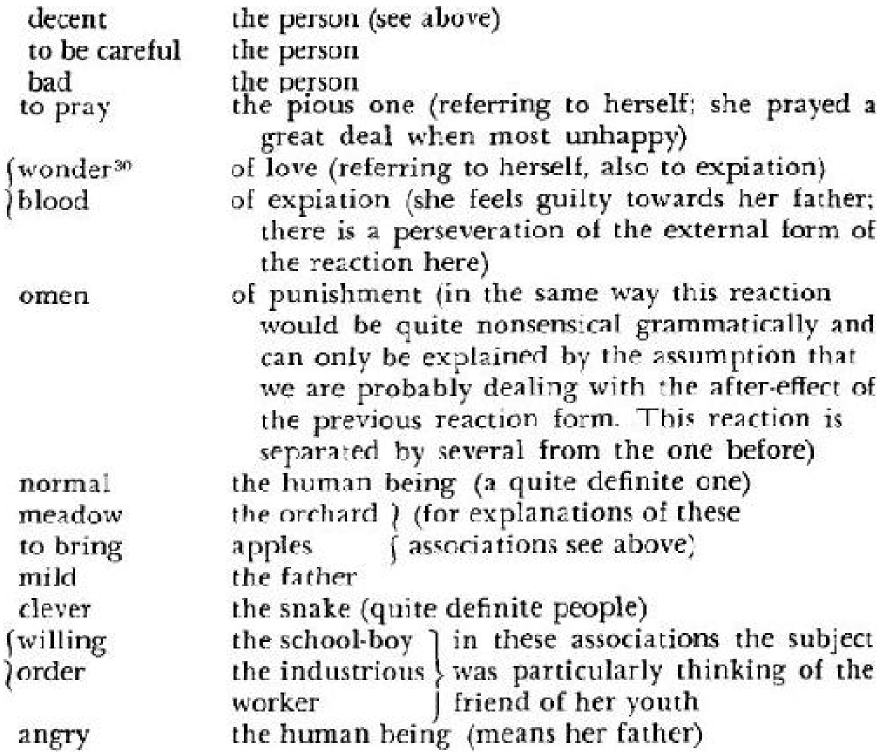


indolent	the human being
virtue	of human beings

In this example there was even a perseveration of the same reaction-word, from which can be gathered how strong is the emotional charge of this idea.

[284] We often find the definite article used in the reaction as a disguise of the complex-constellation. Our subject, for example, used the article 26 times in the reactions under normal conditions; seventeen of these reactions definitely refer to the complex. The connection is less striking under distraction.

[285] We find the phenomenon again in other subjects. To illustrate the complex-reactions here are some relevant examples:



decent	the person (see above)	
to be careful	the person	
bad	the person	
to pray	the pious one (referring to herself; she prayed a great deal when most unhappy)	
wonder[30]	of love (referring to herself, also to expiation)	
blood	of expiation (she feels guilty towards her father; there is a perseveration of the external form of the reaction here)	
omen	of punishment (in the same way this reaction would be quite nonsensical grammatically and can only be explained by the assumption that we are probably dealing with the after-effect of the previous reaction form. This reaction is separated by several from the one before)	
normal	the human being (a quite definite one)	
meadow	the orchard	(for explanations of these associations see above)
to bring	apples	
mild	the father	
clever	the snake (quite definite people)	
willing	the school-boy	in these associations the subject was particularly thinking of the friend of her youth
order	the industrious worker	
angry	the human being (means her father)	

ana so on.

[286] In the distraction experiment the subject did not understand several stimulus-words, namely: *hatred, love, repentance, fall, pleasant, penny, glass, to hammer, entrance, ears, to inhibit*.

[287] It soon transpired on analysis that the subject could not, or would not, understand the first series of quoted stimulus-words, owing to the half-conscious, half-

unconscious effect of her complex. According to her, all these stimulus-words touched most intimately upon the complex that she was trying to suppress.

[288] The stimulus-words of the second series were really not understood because of the acoustic disturbance of the metronome. The subject thus found a further method here of hiding her complex in an apparently unobtrusive way; it is adapted to the situation, for, as the second series of stimulus-words (which do not touch upon the complex) proves, it is easy not to understand stimulus-words, or to understand them wrongly, in the constant noise of the metronome beats of the distraction experiment (to compensate for this, another stimulus-word was introduced into the experiment).

[289] This not wanting to understand corresponds to a repression of the complex that was to a greater or lesser extent conscious. There is no difference in principle from the cases (hysteria!) where not reacting or falsely reacting occurs involuntarily.

[290] Under complex-reactions we have a large group; that of masked complex-reactions. In our subject the masking, so far as we could discern it, was achieved by the following means:

1. By quotations (songs, book-titles, quotations from texts).
2. By the use of unobtrusive general concepts with a quite special meaning with reference to the sense of the complex.
3. By the addition of the article. The reaction thus receives an apparently even more objective appearance; it then appears like the practised reply of an elementary-school child.
4. By misunderstanding the stimulus-words that allude to the complex.

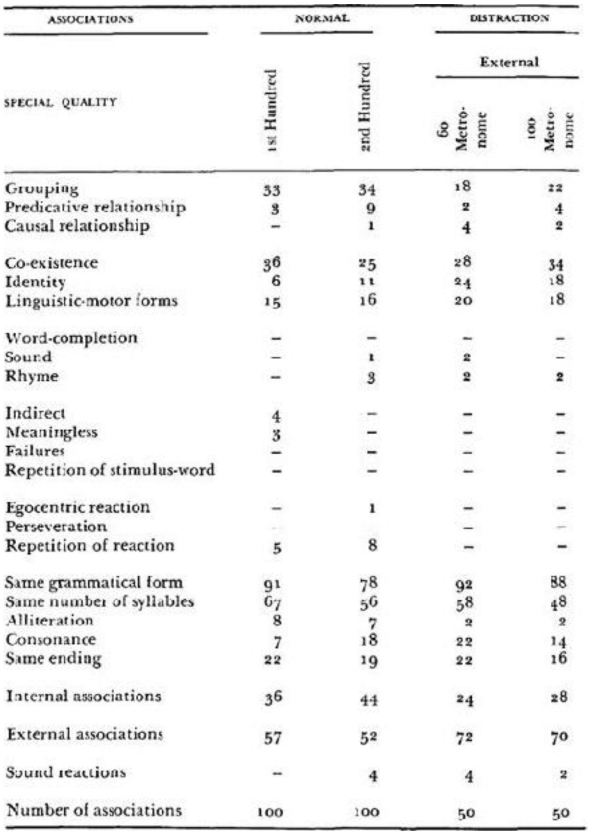
[291] Finally it must be reported that abnormally long reaction-times frequently occur in the complex-reactions; unfortunately, however, no systematic measurements were taken with this subject, so that we cannot develop this point further in the case before us.

[292] *Subject 25.* In the first place, the high figures for grouping and co-existence are striking, both under normal conditions and under distraction. Some of them are far above the mean values. On the other hand, the figure for predicative and linguistic-motor reactions is relatively small and below the mean, particularly in the case of the predicative reactions. The explanation of these figures is probably the extraordinarily objective, steady mode of reaction, which is apparently little disturbed by complexes.

[293] A few reactions with a rather long reaction-time are to be noted. In our experience reactions with a time of more than 5.0 seconds are generally suspect of referring to emotionally charged constellations.

[294] In this subject we find twelve associations with a reaction-time of more than five seconds under normal conditions, in the distraction experiment only three.

Subject 25. Nurse, 22 years of age, South German, intelligent but not educated



ASSOCIATIONS	NORMAL		DISTRACTION	
			External	
SPECIAL QUALITY	1st Hundred	2nd Hundred	60 Metronome	100 Metronome

Perseveration	–		–	–
Repetition of reaction	5	8	–	–
Same grammatical form	91	78	92	88
Same number of syllables	67	56	58	48
Alliteration	8	7	2	2
Consonance	7	18	22	14
Same ending	22	19	22	16
Internal associations	36	44	24	28
External associations	57	52	72	70
Sound reactions	–	4	4	2
Number of associations	100	100	50	50

[295] In the following examples with lengthened reaction-time, the lengthening is presumably to be interpreted as the effect of an erotic complex:

wedding	miss	6.8[31]
to kiss	to laugh	6.0
to love	gladly	5.6
male nurse	wardrobe	8.0
dream	basket	6.4
ripe	fruit	6.6
to bless	to receive	5.8

[296] The subject usually reacts strongly to allusions of an erotic nature and also blushes easily. She admits herself that she was embarrassed at answering to the first three stimulus-words. She also found it awkward to say the word *nurse* which first occurred to her as an answer to the stimulus-word *male nurse*, obviously because she immediately thought of erotic relations. She searched in her surroundings and named the first object she saw in the room: *wardrobe*.

[297] At the stimulus-word *dream*, an erotic thought prevented her from reacting. Instead of giving a reaction according to sense, the subject again let herself be distracted by externals, happened to see the waste-paper basket, and said *basket*.

Thus a senseless reaction was given as a result of the complex. The reactions *ripe / fruit (Obst*) (the subject first thought of “fruit” [*Frucht*]) and *to bless / to receive* are obviously again examples of the same sexual embarrassment.[32]

[298] Distraction by surrounding objects is, as far as we know from our experience in psychopathology, a phenomenon that must be interpreted in both cases as the effect of emotion.[33] In embarrassment or bewilderment, which are caused when the stimulus-word conjures up emotionally charged ideas that the subject consciously or unconsciously tries to repress, the subject lets herself be completely distracted by externals and verbally reacts by simply naming an object from her surroundings. We find this phenomenon very marked in certain hysterics, for example.

[299] Of the sixteen reaction-words, from the experiment under normal conditions, that are repeated we call special attention to: *diligent* five times, *good* three times, *well-behaved* twice, *right* twice. The others are divided among very varied ideas. One can more or less see from these the strict morals of the subject. It is characteristic that these indications of subjectivity disappear under distraction.

[300] In classifying, it was rather difficult always to draw the dividing line with certainty between grouping and co-existence.

[301] Finally, it can be said of the subject that she belongs to an objective reaction-type that is very little influenced by constellations, and which we find again in subject 27 of this group.

[302] The following reactions might illustrate this general objective reaction-type of the subject.

soft	hard
youth	age
sorrow	worry
window	glass
false	right
sweet	sour
wide	narrow
honey	bee
to rinse	to wash
building	wall
sleeve	dress
park	garden
glass	iron
couch	chair
to paint	to varnish
star	moon

fidelity	obedience
to plunder	to catch
freedom	solitude
regret	fear
stork	dove
bike	car

[303] The unusually high number of reactions with the same grammatical form runs parallel to the many groupings and coexistences and confirms what has just been stated.

[304] Distraction is very obvious. There is a decrease of internal, an increase of external associations. We only find sound reactions in the second hundred of the experiment under normal conditions and under distraction; on the other hand, direct associations only in the first hundred, so that our assumed rule of reciprocity between indirect and sound associations would again be correct here.[34]

[305] It must, incidentally, be mentioned that the subject carried the experiments out with great enthusiasm and also made a great effort under distraction to do justice to the higher demands by devoting all her attention to the experiment.

[306] *Subject 26.* The subject has a rather obvious tendency to make rhymes, which increased in the second half of the distraction experiment.

[307] The usual distraction phenomenon did not appear, although the subject does not belong to the predicate type. Marking the beats was done with great irregularity. The predicates increase under distraction; the external associations, particularly the linguistic-motor reactions, decrease; only the sound reactions increase constantly.

[308] Constellations are found mostly in the second hundred of the experiment under normal conditions and in the first half of the distraction experiment. The latter fact shows that the distraction experiment was after all partially successful; for, with the exception of subject 24 of this group, where the distraction experiment was equally unsatisfactory, the constellations disappeared almost completely under distraction in the other subjects.

[309] We here describe individual examples: To the stimulus-word *lamp*, the subject did not react till 20.0 seconds later with *oil-lamp*. She had just before had the pleasant dream that instead of the 9 o’clock meal, which she rarely took, she was getting a new lamp in her room, which she wanted very much.

[310] window glass 10.0 (thought of *vitrine* in between)

The subject thought of a large shop with beautiful glass cases. She had for some time been the private nurse of the wife of the owner of such a shop and was very attached to her former patient. The subject had learned the French expression *vitrine* for “glass case” from the sister of this patient. One can see how a particular thought occurring at the time is responsible for an apparently insignificant expression.

[311] to strike 6 o’clock 2.0

The subject had carried out night duty in a ward, always having to get up at 6 o’clock in the evening.

[312] to paint *peintre* 6.8

This reaction, with a lengthened reaction-time, refers to a year’s stay in French Switzerland. The subject, then a young girl, was admired by a painter; he was also very keen to paint her. In the reaction-word *peintre* there is, besides a masking of the constellation by a quite blunt association, a further constellation, in that the subject in this instance uses, together with the reminiscence of an erotic experience in French Switzerland, a French word. In the distraction experiment she produces the reaction

painter *peintre* 13.0

with the same constellation. The characteristically long reaction-times in both places are worthy of note.

Subject 26. Nurse, 21 years of age, Swiss, secondary-school education

[313] In rapid succession the following reactions occur:

wedding	tomorrow	2.2
come	tomorrow	1.4

This repetition is not a coincidence. The subject was celebrating her saint’s day the day after the experiment under normal conditions took place. She was happy, for she wanted to go out, and she had been invited out for this day and would be receiving all the congratulations at home; among these she was also expecting a letter from her sweetheart.

[314] Further, we find the reactions:

rich	in love	2.0
poor	in virtue	2.2

The first is a quotation from Ernst Zahn’s novel *Albin Indergand* (1901). It refers to a love-story and has the significance of a complex quotation for the subject, like the one we discussed in subject 19 in the group of educated men and subject 24 (uneducated women). The second is an analogous but original form. The subject was thinking of another nurse with whom she had had an argument the day before on the subject of “love,” in which the other had maintained a much less idealistic attitude to the question than had the subject. The stimulus-word *poor* has become associated with the previous stimulus-word *rich* and the emotionally charged reaction connected with it, whereupon she became conscious of the contrast between her “ideal of love” and that of the other nurse. By *poor in virtue* she means the other nurse.

[315] The same thought gave rise to the following quotation:

to despise	you think	2.2

The quotation is word for word as follows:

Perhaps you believed
I should hate life,
[Flee to the deserts,
Because all dream buds
Had not bloomed?] (Goethe, *Prometheus*)

The subject knows only the first two lines of this quotation, she had quite forgotten the part in brackets. At this, the subject vividly thought of the other nurse and her low views on the subject of “love.” One sees from this how closely related expressions and quotations of this sort become associated with feeling-toned complexes, helping to create the infinitely copious unconscious verbal material used by feeling-toned complexes, which makes possible, for example, the poet's countless variations on one single thought.

[316] A further quotation:

finally	does not last for ever	5.6

again refers to her love-complex. The reaction-time is strikingly long. The subject was thinking of the "brother of a woman friend," who turned out to be her sweetheart; she was anxiously awaiting news of whether he had accepted a certain post abroad, wishing he would not go.

[317] At the stimulus-word *to kiss* the subject reacted in a tone of surprise: "*To kiss*—yes—I cannot tell you that; we have just been talking about something." She meant the discussion with the other nurse, who said that kissing was something dirty. To the stimulus-word *time* the subject reacted:

time	according to	2.0

The next reaction but one was

to reign	according to …	3.8

[318] At *to reign* an older nurse who was in charge of the whole department came to her mind. A trifling incident of about that time made the subject think: "She regiments us in everything." The stimulus-word *to reign* released this thought, which the subject could not utter; in its place appears the reaction-word *according to* used almost immediately before, which had a meaning when used with *time* but with *to reign* at the most only a remote one. Thus the gap in the reaction produced by the affect is filled by a reaction-word already used. A similar phenomenon was already observed in subject 19 in the group of educated men, who in an experiment under fatigue always reacted with *yesterday* to a series of stimulus-words that touched upon the complex.

[319] The reaction

to love	in need of	4.0

is accompanied by a sudden change of facial expression. This phenomenon refers to her love-complex and is important for us because we find similar reaction-phenomena (changed facial expression, sudden lowering of voice) in the pathology of associations, where emotionally important complexes are concerned.

[320] At

to choose	advice	3.2

the subject thought that one must be very careful in one’s choice of a husband; she thought that one ought to have good advice when having to make one’s choice.

[321] A quotation, the reaction

hope	does not let one sink	1.8

is based on a recent letter which the young man from Western Switzerland (*le peintre*) had written to her a short while before, and from which it transpired that he had not yet given up hope of winning her.

[322] On the reaction

love (*lieb*)	empty (*leer*)	3.0

the subject put an unusual inflection; it refers to her own love-life and must be put by the side of the reaction:

to love	in need of	4.0

with a change of facial expression.

[323] The reaction

lazy	why	1.8

is again a quotation. The text on which it is based runs as follows:

> The girl came to the spider
> And the spider said: Why so late?
> I have been spinning threads for three hours
> See how finely and delicately they are twisted!

The content of these lines is summarized by the stimulus-word *lazy*. Also the reaction is determined by sound in the stimulus-words *spät* (late) and *gedreht* (twisted). An obvious condensation (Freud) of the situation and apparent form into the word *träge* (lazy) has occurred in the subconscious; this is already proved by the fact that the reaction-time is quite short and therefore there can be no question of a conscious search for quotations. One also sees that the subconscious or unconscious likes to associate quotations or complexes, often in such a way that fragments of quotations and songs which happen to have been picked up, and the continuation of which the subject does not know, are directly connected with the complex. In our present case, for example, the subject does not know the poem by heart.

[324] We still have to prove that behind this quotation there lies a feeling-toned thought.

[325] The verse, taken from a school poem, corresponds to the feeling-toned situation at the time. The subject was then, as already mentioned, on night duty in a ward. She

slept during the day. In the morning she was relieved by the nurse who was on day duty in the same ward; she had several times in the last few days been annoyed that this nurse relieved her so late; we find the expression of this in this reaction.

[326] Behind the seemingly insignificant, quite impersonal reaction:

something	important	1.2

is concealed the thought of the saint’s day on the morrow.

[327] To the stimulus-word *to woo* there was no reaction. The cause of this is once more the conversation with the other nurse about love. She recounted that she had permitted herself the joke of writing to an obscure marriage bureau, whereupon a widower had been recommended to her by this bureau as a good match. This idea displeased the subject very much.

[328] To the stimulus-word *doing* the subject reacts *and not doing* (10 secs.). Behind this superficial reaction the thought of the argument about love is once more concealed.

[329] When a complex is hidden behind quotations or superficial reactions of this sort, the reaction-time is usually short. While in the so-called failures attention is quite absorbed by the complex that is to be suppressed (that is, hidden from consciousness or from the experimenter) here a division of attention takes place. One part is devoted to the verbal reaction and this then bears a very superficial (linguistic-motor, sound) character; the other part is occupied by the emotionally charged idea. This part is frequently repressed and does not clearly emerge to consciousness. This interpretation is also confirmed by the frequent observation that such quotations and superficial reactions are produced with the most indifferent expression in the world although the observer, for example, knows that they refer to a strong emotionally charged complex and are conditioned by it.

[330] The main part of the emotionally charged complex becomes split off and repressed. At the same time the chain of ideas unfolding in consciousness contains as representative of the complex only a quotation, for instance; this appears after a short reaction-time and indicates to the expert that under this cover an important complex is exerting its influence in the subconscious.

[331] In other cases, where the affect is already shown in the quality of the reaction (intonation, expression), this split does not take place; the reaction becomes more difficult and the reaction-time lengthened (see the example *to love / in need of;* 4.0).

[332] In the distraction experiment we find in subject 26, in the group of uneducated women, among the few reaction-words (*bicycle, Zurich, clear, sad*) that are repeated several times, two in which a complex is probably the cause of the repetition.

[333] About the reactions

bike	wheel	tram	bicycle

the subject afterwards explained that her sweetheart cycled a lot, which immediately came to her mind when she heard the stimulus-words. The reactions

fire	Zurich	station	Zurich

remind her that in the discussion about love she had defended the town of Zurich and its inhabitants against the other nurse. The reactions

moved	sad
mild	sad

are connected with incidents in her family. In the reactions

sin	world	0.8
remorse	death	1.2

a recent accident was on her mind, in which a patient managed to drink some Lysol from an instrument dish. There were no serious consequences but the incident had happened in the ward in which the subject was on duty and had left her with a very unpleasant impression and a great feeling of guilt; hence also the perseveration in the above reactions.

[334] *Subject* 27. The result of the experiment has the greatest similarity with that of subject 25 of this group. Admittedly the distraction phenomenon is not so marked (the subject gave her whole attention to both experiments). Reactions from the sound group are completely absent and the number of linguistic-motor forms is very small. The co-existences show high figures. The predicates are few, egocentric reactions absent, which indicates a very objective grasp of the stimulus-words. The figures for the same grammatical form of the stimulus-word and reaction are strikingly high, as in case 25 of this group. Thus our subject also belongs to the same quite objective reaction-type without demonstrable constellations. Many associations have lengthened reaction-times, without our having a retrospective explanation for it. We do not possess a more detailed analysis.

[335] *Subject 28*. The predicates are relatively few (in the experiment under normal conditions, for example, only 8.5 per cent instead of 20.4 per cent, the average for uneducated women). The groupings, too, are below average in the experiments under normal conditions and under distraction; the linguistic-motor reactions, on the other hand, are above average for uneducated women (the latter is 24 per cent under normal conditions and 28.8 per cent under external distraction). On the whole, we are confronted by a case with relatively few internal and many external associations.

Subjects 27 and 28. Nurses, 23 and 28 years of age, Swiss, elementary-school education

Sound reactions	–	–	–	–	–	2	4	8
Number of associations	100	100	50	50	100	100	50	50

[336] Although, or rather because, the general reaction-type appears somewhat superficial, the distraction experiment was successful, considering that uneducated women with many predicatives are usually more difficult to distract. Even if the external associations are no more numerous in the second part of the distraction experiment than in the first hundred under normal conditions, the internal associations have definitely decreased, while the sound reactions have increased.

[337] In the second hundred under normal conditions we have an increase of internal associations. At the same time, we find (as so often) an increase of constellations, which are probably, as many cases show, the cause of this shift. (The fact that among the stimulus-words of the second hundred there are more than in the first hundred of the kind likely to awaken emotionally charged concepts may have an influence here.) In the first hundred under normal conditions six constellations, in the second hundred under normal conditions ten, in the distraction experiment two can be demonstrated. In the distraction experiment they are much less frequent. We have here almost exclusively complex-constellations.

[338] The complex is linked to a romance with an unhappy ending. The subject was disloyally deserted by her lover after a long relationship.

[339] The long reaction-times (mostly more than five seconds) are almost exclusively confined to these complex-constellations. Examples:

male nurse	hospital orderly	11.4	(the lover wa
heart	stomach	6.4	
to stroke	to love	5.6	
to part	to go	5.6	
dear	angry	8.8	
freedom	imprisoned	6.0	
to despise	respected	18.4	
band	to tear up	5.2	
false	falseness	7.2	

[340] The subject did not really want to give an account of the few remaining constellations and long reaction-times, which cannot easily be recognized as belonging to the complex; they are therefore all the more suspect.

[341] Here again we see the specific way in which the complex is manifested, i.e., the lengthened reaction-times. (This does not mean that these do not also occur in other cases, e.g., with rather difficult, unfamiliar stimulus-words.)

[342] We have already found lengthened reaction-times as complex-phenomena (subjects 26 and 27 of this group); here they are almost exclusively complex-characteristics. There is a transition to the so-called “failures,” where there is no verbal reaction at all.

[343] The repetition of reaction-words is almost exclusively limited to the experiment under normal conditions and concerns sixteen different words; the majority of them designate things from the everyday life of a nurse.

[344] *Subject 29.* A glance at the ratio of the predicate to the groupings tells us that the subject must be classed as a predicate type. In keeping with the rule for the predicate type we find no clear effect of distraction. Sound reactions and indirect associations only occur in the first part of distraction. Egocentric reactions are well represented and evenly distributed. The highest number of internal and the smallest number of external associations occur again in the second hundred of the experiment under normal conditions. There we also see a maximum of failures (7), which are nearly all caused by a complex. Unfortunately the subject never gave us an exact explanation and her retiring character induced us not to insist on one. The subject only confessed that memories of particular events in her family were largely behind the failures and the lengthened reaction-times. In a few instances unusual stimulus-words were responsible.

[345] *Subject 30.* Distraction was clearly successful; it is mainly characterized by a decrease of groupings and increase of linguistic-motor forms; the number of

predicates, although fairly numerous, is somewhat more stable. The largest number of perseverations occurs under distraction, particularly in the second hundred of the distraction experiment. There are no egocentric reactions. From the type of reactions it is not clear whether constellations or complexes play a part in the associations of the subject or not. It is easier to draw some conclusions from the reaction-times occurring, for example, after provocative stimulus-words, e.g.,

Subjects 29 and 30. *Nurses, 18 and 27 years of age, Swiss, elementary school education*

rascal	without means	12.6

[346] But we lack a detailed psychological analysis in this case. In the distraction experiment, repetitions of the form of the reaction occur; mainly we find reactions in the form of a whole sentence, e.g.,

sin	man sins
repentance	man repents
love	people love
strong	man is strong
hatred	people hate, etc.

[347] Strikingly long reaction-times do not occur here; whether the repetition of form, particularly the reoccurrence of the word *man*, indicates similar complex-phenomena to those we found in subject 24 of this group cannot be established.

[348] Seen from outside the associations of our subject make a very objective impression, without many subjective constellations. The rather variable and often strikingly long reaction-times, however, indicate that, behind the apparently objective reactions, complex-constellations are probably to be found after all. For practical reasons it was not possible in all cases to carry out a thorough psychological analysis, as could fortunately be done with a number of subjects.

[349] *Subject 31*. The reactions are characterized by the great predominance of predicates, which make up the majority of the large number of internal associations. There is a definite inclination towards value judgments, which, however, do not have an expressly subjective (egocentric) character. The reactions betray a strong involvement with the experiment and with the meaning of the stimulus-word. In this way, in spite of a certain reticence and reserve, the more intimate content does emerge rather clearly. The subject is a very capable and practical housemaid, very religious. Occasionally she thinks of marriage. In the reactions under normal conditions the following reactions are repeated:

Subject 31. Maid, about 27 years of age, Swiss, elementary school education, fairly intelligent

God	twice	child	5 times

[350] Shortly before the associations were obtained the subject was attacked by a large dog, which greatly frightened her.

[351] The reaction *dog* was repeated four times. Once the subject showed a strong perseveration with the image of the dog.

to growl	dog
knot	the knots (lumps) on the paws of the dog

[352] The reaction *wolf* is also repeated twice. To the stimulus-word *cunning* the subject reacts with *wolf*, volunteering that actually *fox* had occurred to her first. These reactions and repetitions clearly show feeling-toned complexes and therefore a strong personal participation.

[353] The distraction experiment, which incidentally was carried out very inadequately, had no effect at all. Thus we have here the same behaviour as in the predicate types described above.

[354] The failures, numerous with this subject, are distributed as follows: Of the seven failures under normal conditions, five concern emotionally charged stimulus-words such as *heart, custom, flatterer, faithful*, *rich*, *revenge*, etc. In the two series of experiments under distraction, the failures (ten in the one and five in the other) concern 8 per cent of emotionally charged stimulus-words in the one and 4 per cent in the other—a further proof that the majority of failures can be attributed to emotional causes.

SUMMARY

[355] In the group of uneducated women we have eight subjects, with ages ranging from 18 to 28, and altogether 2,400 associations. From each subject we have two hundred associations under normal conditions and one hundred under external distraction.

[356] Most of the subjects are fairly intelligent. More than half have attended secondary as well as primary schools. Seven subjects usually speak the Swiss dialect, only one speaks a South German dialect, which is more like standard German. Seven subjects are nurses, one is a maid. Two subjects react as predicate types; with neither was the distraction experiment successful. With a third subject, who gave a good number of predicates without actually belonging to the predicate type, the distraction experiment also failed; partly, no doubt, because the subject, in order not to let her

attention be distracted, did not always make the strokes to the beat of the metronome at the stimulus-words. The distraction experiment was only partly successful with a subject with many groupings and no constellations. She almost doubled her effort in the distraction experiment, in order to pay attention to the stimulus-words as well as to the metronome beats.

[357] With the remaining four subjects the distraction experiment was successful, although in general these subjects also strained their powers in the distraction experiment and made considerably more effort than in the experiment under normal conditions, because they found it more difficult than the educated subjects to divide their attention. On the whole the uneducated women were the group least able to divide their attention. The sound associations play a much smaller role as distraction phenomena than in the groups of educated subjects. Two subjects are of a purely objective type with few predicates, practically no constellations and strikingly many reaction-words with the same number of syllables as the stimulus-word. In two other subjects (24 and 26), complex-phenomena in various forms are predominant. In three subjects an increase of internal and a decrease of external associations can be observed in the second hundred of the experiment under normal conditions; it usually appeared that the complex-phenomena were also more obvious in the second hundred under normal conditions, while they diminish in number under distraction. In the marked cases, e.g., subject 24, the manifestation of the complex in the second hundred of the experiment under normal conditions is certainly not dependent on the increase of emotionally charged stimulus-words. It also appears with stimulus-words that for other people do not have this property at all.

IV. UNEDUCATED MEN

[358] In the group of uneducated men we tabulate only a summary for the first six cases; the columns omitted are of no special interest. For the group of linguistic-motor forms, we have obtained the following mean values, from which none of the six subjects deviates significantly: experiment under normal conditions, first hundred 27, second hundred 30; external distraction, first half 22, second half 34. Definite complex-constellations are hardly demonstrable, and in almost all cases detailed analyses are lacking.

[359] *Subject 32*. The external associations predominate over the internal but not to the same degree as in the educated subjects. The effect of distraction is clear: in the second hundred of the experiment under normal conditions we see the number of internal associations fall and the external ones rise somewhat. The figures for failures and egocentric reactions (4, 8, 6, 4) are strikingly high; they exceed the mean for these reaction-forms. In the absence of a more detailed analysis it is not really possible to find the significance of the failures in each association. There are

practically no definite constellation-associations; neither do the reaction-times—apart from the few failures—betray any complex-constellation. They vary within narrow limits, 0.6 to 2.6 seconds.

[360] *Subject 33.* Predominance of external associations, as in the preceding case. In the second hundred of the experiment under normal conditions, an increase of internal and decrease of external associations appears. We have been able to explain this phenomenon where we met it in other groups up to now, almost without exception, by the fact that the feeling-toned association-complexes emerge more clearly. Probably this is the case here too; yet the constellation-associations are here not very obvious and we possess only a fragmentary analysis. The sum of reaction-times in the second hundred is greater than in the first; the longer reaction-times are more numerous. In the second hundred there occurs significantly the reaction *family / alone,* 4.4 secs., the longest reaction-time that occurs with this subject.

[361] The young man is engaged to a nurse. A series of reactions with somewhat longer reaction-times are probably determined by this thought-complex.

[362] We find the most marked distraction phenomena in the first part of the distraction experiment, where we also find six sound associations.

[363] We find indications of constellations in our subject in single reactions referring to military service.

pupil	soldier
faithful	soldier
row	rank

Others refer, with fairly great probability, to his engagement and his fiancée:

dear	to trust	1.6
hope	at last	1.6
wreath	ring	3.2
fidelity	to let go	2.4
everywhere	alone	?
family	alone	4.4
to part	to come together	1.6

[364] These reaction-times, which are rather long in relation to the other associations, support this interpretation. We find practically no quotations or the like in this or in the preceding subject.

[365] *Subject 34.* The distraction experiment was not very successful; nevertheless it must be taken into consideration that the use of associations belonging to the sound and residual groups is more frequent in the distraction experiment than under normal conditions; the egocentric reactions disappeared in the distraction experiment, a

phenomenon that may be regarded more or less as the effect of distraction. No constellation-and complex-associations are manifest.

[366] *Subject* 35. The subject can just be included in the predicate type. A certain effect of distraction can nevertheless be noted. We see the internal associations decrease noticeably in our table and a definite increase of external associations only in the second part of the distraction experiment; on the other hand there is a maximum of sound reactions in the first part of the distraction experiment. Perseverations and egocentric reactions are completely absent. No constellation-associations are evident. We quoted this case (one of the preceding cases from this group could also have been taken) in our discussion on constellations and complexes (see subject 18, educated men) as an example for those cases in which we find the first constellations and/or subjective reminiscences.

Subjects 32-37. Male nurses: (*32*) *40 years of age, Swiss, elementary-school education, fairly well read;* (*33*) *about 25, South German, elementary-school education;* (*34*) *54, secondary-school education, intelligent, rather neurasthenic;* (35) 37, *elementary-school education;* (36) 30; (37) *36, secondary-school education*

Number of associations	100	100	50	50	100	100	50	50	100	100	50	50

[367] *Subject 36*. The internal associations diminish in number in this case as in the first few cases of this group. The predicates especially are very few. Define effects of distraction: the internal associations decrease both in the second hundred of the experiment under normal conditions and in the distraction experiment, particularly in the second part. Sound reactions, rhymes, and indirect and senseless reactions are

numerous in the distraction experiment, particularly in the first part. In the second part they diminish again somewhat, but on the other hand the decrease of internal and increase of external associations is most marked. The figures for the same grammatical form are, as in the next case and in nos. 25 and 27 in the group of uneducated women, strikingly high (86 in the first hundred under normal conditions, 44 in the second hundred; 88 in each of the two halves of the distraction experiment). In keeping with this finding, egocentric associations are absent and the constellation-associations completely recede into the background and cannot be clearly recognized, as in the cases quoted.

[368] In the second part of the distraction experiment there appears a certain amount of repetition, probably in embarrassment and as a distraction phenomenon:

17.[35] door	castle (or lock)
55. hall	castle hall
57. bridge	castle bridge (drawbridge)
69. shield	castle shield (or lockplate)
81. cellar	cellar-door
87. corridor	door

[369] *Subject* 37. Among the fairly abundant internal associations there are mainly groupings, while the predicates are not particularly numerous. The linguistic-motor forms are relatively few. A glance at the ratio of internal to external associations shows at once that the distraction experiment was successful; in fact the numbers obtained in the second hundred of the experiment under normal conditions foreshadowed it.

[370] Our subject is like subject 36 of this group, and subjects 27 and 25 of the group of uneducated women, in the marked prominence of groupings and the figures for the same grammatical form, the decrease of predicative relationships and the almost complete absence of egocentric reactions and constellation-associations. We have here an objective balanced reaction-type.

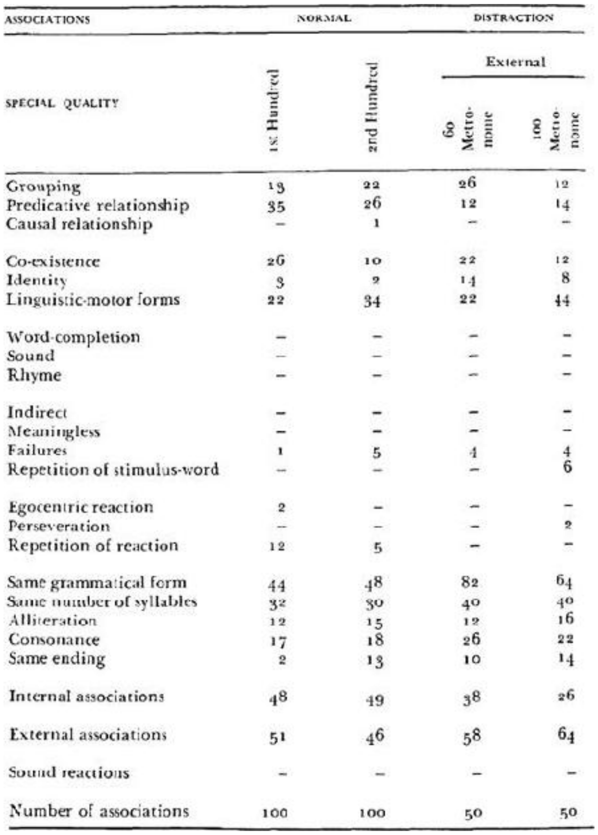
[371] This case is distinguished from the others by the predominance of subordinations and definitions within the groupings, while the other three subjects mentioned previously produced more actual co-ordinations.

Stimulus-word	*Subject 25* (Uneducated women)	*Subject 27*	*Subject 36* (Uneducated men)	*Subject 37*
Sunday	Tuesday	Monday	Monday	holiday
schoolboy	girl	teacher	teacher	boy
head	foot	arm	neck	part of human being
ink	pen	pen	pencil	writing material
bread	meat	cheese	flour	food

lamp	oil	candle	light	object in a room
tree	chair (?)	bush	bush	plant
wood	coal	coal	coal	fuel
slate-pencil	pen	pen	blackboard	school implement
fruit	plum	apple	vegetable	fruits
helmet	glove	sword	cuirassier	head-covering

[372] *Subject 38.* The subject may perhaps be included in the predicate types, although the predicates do not predominate greatly in the second hundred. Strikingly many co-existences. No reactions in the sound group. In the residual group the number of failures is noteworthy. The maximum (five) occurs in the second hundred of the experiment under normal conditions. The sudden occurrence of 6 per cent of repetitions of the stimulus-word in the second part of the distraction experiment is surprising. We also find 2 per cent of perseverations there. In the second hundred of the experiment under normal conditions the number of internal associations rises and that of external associations falls, as we have already found several times in connection with the emergence of complex-constellations. In spite of the predicate type, the distraction experiment was successful. The number of internal associations decreased and that of external associations increased more and more. The predicates in particular diminish noticeably in the distraction experiment.

Subject 38. 17 years of age, technical-school boy, fairly intelligent, nervous



ASSOCIATIONS	NORMAL		DISTRACTION	
			External	
SPECIAL QUALITY	1st Hundred	2nd Hundred	60 Metronome	100 Metronome

External associations	51	46	58	64
Sound reactions	–	–	–	–
Number of associations	100	100	50	50

[373] The exact figure for new constellations cannot be given; nevertheless a series of constellations exists, besides an enormous quantity of reminiscences from subjects taught at a grammar school. Individual associations with very long reaction-times are striking, e.g.:

exercise-book	squared	7.4
book	interesting	10.1
obstinate	the enemy	17.2
to stroke	*caresser* (french)	6.4
evil	devil	10.4
wicked	devil	28.0
to come	the yellow peril	8.4
to kiss	Oberon	6.8
to love	mother	13.0
dear	mother	9.0
strange	a poem	11.0
to disgust	dirty	6.8

[374] In the distraction experiment the reactions with strikingly long reaction-times are very few. Probably a more detailed analysis would have found one or more

complexes behind these reactions. Eroticism, school, and fear of a small operation were probably the decisive reasons for the lengthening of the reaction-times.

SUMMARY

[375] In the group of uneducated men we have seven subjects and 2,086 associations. All subjects are fairly intelligent but with the exception of subject 37, who has received a secondary-school education, and subject 38, who is attending a technical school, they have all only had elementary-school education. Four subjects are German Swiss, speaking the ordinary dialect; one subject is South German but has long been resident in Switzerland, and the Swiss dialect therefore came quite naturally to him. Only one subject speaks the Swabian dialect, which approximates more closely to standard German. One subject, the technical school boy, speaks standard German at home.

[376] Two subjects may be considered to be predicate types; as in most subjects of this type, distraction was not really successful in the first case, but it was in the second. With one subject, who produced relatively few internal and many external associations in the experiment under normal conditions, distraction was also not very successful. In all other subjects the effect of distraction was obvious (in all subjects of this group only external distraction was used).

[377] Sound associations as signs of distraction never occur to the same extent as with the educated subjects.

[378] Two subjects (36 and 37 of this group) belong to a type having very many groupings, few predicates, and many reactions with the same grammatical form; they are distinguished at the same time by the paucity of egocentric reactions and constellations. We also meet this type in the group of uneducated women (subjects 25 and 27). For the rest, the whole group of uneducated men is distinguished by the fact that constellations and complexes are few in number and can only be guessed at; this does not mean, however, that, within narrow limits, the fluctuations of the reaction-times do not betray the workings of complexes. Quotations and similar reactions suggesting a complex were found only rarely in this group, an exception being the youngest of the group, the technical school boy. He reacted with many subjective reminiscences and a number of constellations, which may in part be interpreted as complex-constellations.

[379] In subjects 33, 34, and 38 we find an increase of internal associations in the second hundred of the experiment under normal conditions. Whether this can always be explained by the effects of complexes cannot be ascertained with certainty in all cases.

[380] In general the uneducated men are distinguished from the uneducated women in our experiments in that subjectivity and feelings are less prominent. This difference hardly exists in the educated subjects. Among the educated men there are as many subjective types who react strongly with feeling as there are among the women; the educated men have more feminine characteristics in this respect than the uneducated.

[381] Finally, it may be permissible to point out once more that an overwhelming number of the complexes we have discovered in our subjects are erotic. In view of the great part played by love and sexuality in human life, this is not surprising.

B. CALCULATIONS OF AVERAGES

I. Experiment under Normal Conditions

[382] Having discussed the individual subjects, we still have to study the interrelations of the groups of reactions. In the individuals the proportions of these is markedly variable, as a glance at the previous tables shows. Besides the individual causes, one of the main reasons for these variations is the intensity of concentration, the effect of which we have already mentioned several times. The fact that some individuals tend to react with internal associations and others with external ones is primarily a question of attention. Everyone gifted with speech has all the different qualities of association at his command: which quality of association he expresses depends in the main only on the degree of attention devoted to the stimulus-word. Where our distraction experiment was successful—that is, where the conditions of the experiment were carried out in the way intended by the experimenter—the identical unequivocal phenomenon appeared: the external associations and sound reactions increased at the expense of internal associations. The type of reaction shifted towards the accustomed and canalized and thus to the mechanical, concrete and verbal connections. With increasing distraction the effect of the "law of frequency" increases, ideas that are often spatially or temporally related being evoked. The less an idea is focussed upon, the more the valency of associated, mainly linguistic, elements increases, the threshold is lowered and these elements are therefore produced again.

[383] We do not wish to discuss here the different psychological theories of attention. We regard attention as a state occurring in association-complexes and ultimately characterized by muscular tension, which provides the psychophysical basis for the complex. The stabilizing of the idea in the field of consciousness seems to be the aim of the physical echo. It is probably through the somatic connection that the idea, or the "feeling" replacing it, is kept in focus. It becomes a "directional idea" (or a "directional feeling"). From it result two types of effect:

(1) ideas promoting all associated ideas, particularly those associated with direction,

(2) ideas inhibiting all ideas not associated, particularly those not associated with direction.

[384] If the intensity of concentration is raised for a non-associated idea, then the directional idea is correspondingly shifted from focus, i.e., it loses intensity. Its impact decreases correspondingly: thus the difference in the threshold value of all other associations becomes smaller. The directional selection becomes more difficult and is increasingly subject to the effect of the law of frequency, i.e., all those associations which, through practice and habit, form the largest component of consciousness come to the fore. The law of frequency now assumes the role previously played by the directional idea. As regards our experiment, this means that ideas already automatized and condensed in language assist the subject in his effort to comprehend the meaning of the stimulus-word and to work it over.

[385] In the act of apperception and the further working on the stimulus-word, all these purely linguistic connections are suppressed, so that in part they manifest themselves only very faintly and vaguely and in part they remain completely unconscious. If the linguistic connections enter the field of consciousness, the higher associations are pushed into the background; some of them faintly reverberate and some remain unconscious (according to Wundt “unnoticed”). (It is possible that they are not even formed, but this is difficult to prove.) In linguistic mechanisms, however, the process has not yet reached its lowest level; mere repetition of the sound reaction is suppressed during the mechanical linguistic reaction. If, by further lowering of attention, we remove the linguistic mechanisms, which in most cases still possess some meaning, the sound reactions come to the fore; these represent the lowest level of linguistic reaction and therefore remain constantly below the threshold of consciousness in everyday life. In the process of development of the child’s speech, sound reactions, as is well known, still play a fairly important part; later they are increasingly suppressed and usually enter into the unconscious, from which they can under normal conditions be brought up only with a certain effort.

[386] We have deliberately discussed only the effect of distraction on linguistic functions. We note in addition that the law of frequency also applies to the selection of internal images. It struck us how often old childish memories cropped up, even with quite everyday objects, in the state of internal distraction (N.B. decidedly more frequently than in the normal state).

[387] In the individual accounts we pointed out the similarity between the distraction phenomenon and manic reaction. The reactions under distraction are in no way different from manic reactions as found by Aschaffenburg and observed by us in many manic associations. Liepmann,[36] who in a recently published monograph

explains *flight of ideas* as a result of a disturbance of attention, reached a similar view to ours. Considerations such as Liepmann makes in his work have for some time pointed directions in our experimental work. The results of our experiments confirm Liepmann's views. As regards the psychological mechanism of flight of ideas, our views are completely in agreement with Liepmann. We therefore refer to his monograph.

[388] Aschaffenburg has introduced us to another reaction-type similar to the manic, the fatigue type. Other investigations, carried out under Kraepelin's direction, report analogous results under the influence of alcohol. Aschaffenburg considers, as is well known, motor excitation responsible for the occurrence of sound reactions. An obvious objection to this interpretation is that the conditions described are to a high degree characterized by disturbance of attention. It has been proved by our experiments that sound reactions are, one might say exclusively, caused by disturbance of attention. The motor excitation is a probably inessential side-effect which, at the most, could be the cause of the disturbance of attention. The latter seems to be the case in fatigue and alcoholism. In manic flight of ideas another factor must certainly also be considered as a cause of disturbance of attention, the specific excitation, the psychological nature of which is still quite obscure to us. Disturbance of attention due to motor excitation in fatigue and alcoholism could in our view be interpreted thus: the physical correlates of the attention phenomenon, the muscular tensions, become under the influence of motor excitation shorter and more variable. The psychophysical basis of accentuated ideas thus reaches a degree of instability that is represented psychically as a weakness of the directional idea. According to Liepmann's principles, from this weakness of the directional idea flight of ideas must result, which in the association experiment appears as sound reactions, etc. It is possible that in acoustic linguistic experiments motor excitation, which is of course also transmitted to the linguistic-motor system, furthers the release of the mechanical reaction; but it is never its sole cause.

[389] From this we may expect the occurrence of a blunt reaction-type or a sound reaction wherever there is a disturbance of attention; conversely we may suspect a disturbance of attention where sound reactions occur.

[390] This fact appears to us of great diagnostic value; it is, moreover, an essential condition for the understanding of the reactions generally.

[391] Because of the relatively great variations in the individual figures, a general survey of our figures is difficult; we have therefore compiled tables in which the arithmetical means of certain groups have been calculated in percentages to make comparison easier. We realize that a calculation of averages from figures of such diversity is a somewhat hazardous undertaking. Even if the quantitative relation of the individual groups to each other is somewhat variable, we are nevertheless

convinced that at least the main figures, that is, those for internal and external associations and for sound reactions, do present a true picture of the mode of reaction. The quantitative interrelation of certain special groups, e.g., particularly of co-existences, is partly subject to certain sources of error that are caused by the selection of stimulus-words. It is certainly clear that, where nouns only are used, reactions show ratios rather different from those brought about by mixed stimulus-words. Nevertheless our relative figures retain their value, as all subjects were given the same set of stimulus-words.

[392] We have classified our material according to different criteria; first of all the question of the relation of educated to uneducated subjects interested us. Aschaffenburg has found, as is well known, a relatively strong predominance of external over internal associations in his educated subjects. On the other hand, Ranschburg and Balint have found a marked predominance of internal associations in uneducated subjects. See herewith Tables A and B for the first and second hundred of normal associations.

[393] Our uneducated subjects were almost all male and female nurses of the hospital. We must now confess that this selection of uneducated subjects is not a particularly good one, for among the nursing staff there are many individuals who are above the low average level of education. It might be better to substitute the term “half-educated” for “uneducated.” The level of education and intelligence of the male subjects is in general somewhat above that of the female subjects.

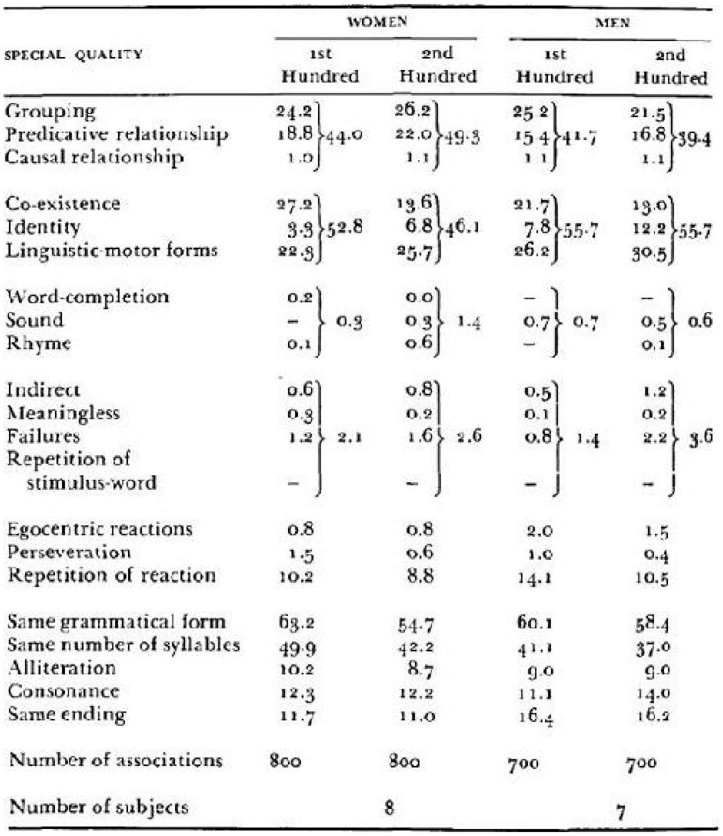
[394] The female subjects show a relatively high number of internal associations; strangely enough the number of internal associations rises considerably in the second half of the experiment, the predicates particularly showing an increase. In addition there is an increase in the residual group and in the sound reactions. There is probably a connection between the increase of predicates and of linguistic-motor forms and the decrease of correspondence of grammatical forms. The figures for linguistic connections are very high.

[395] The male subjects show in general a blunter reaction-type than the female subjects. The second hundred does not differ significantly from the first, only the figures for indirect associations and for consonances show a rather striking increase.

[396] The increase of failures in the second hundred of both groups may perhaps be attributed to the unfortunate coincidence that the number of feeling-toned stimulus-words is somewhat greater in the second hundred than in the first. As we have seen, the failures mainly coincide with feeling-toned stimulus-words. It is noteworthy that the men produce a larger number of egocentric reactions than the women, as well as a definitely smaller number of predicates.

[397] The egocentric reactions, i.e., the influence of personal wishes and values, is probably connected with the number of perseverations; this is somewhat higher for the women than for the men but alters in accordance with the decrease of egocentric judgments, a finding that will be confirmed in the future. We attribute this to the fact that it is mainly feeling-toned reactions that have a tendency towards perseveration, as we have already frequently pointed out in the individual accounts.

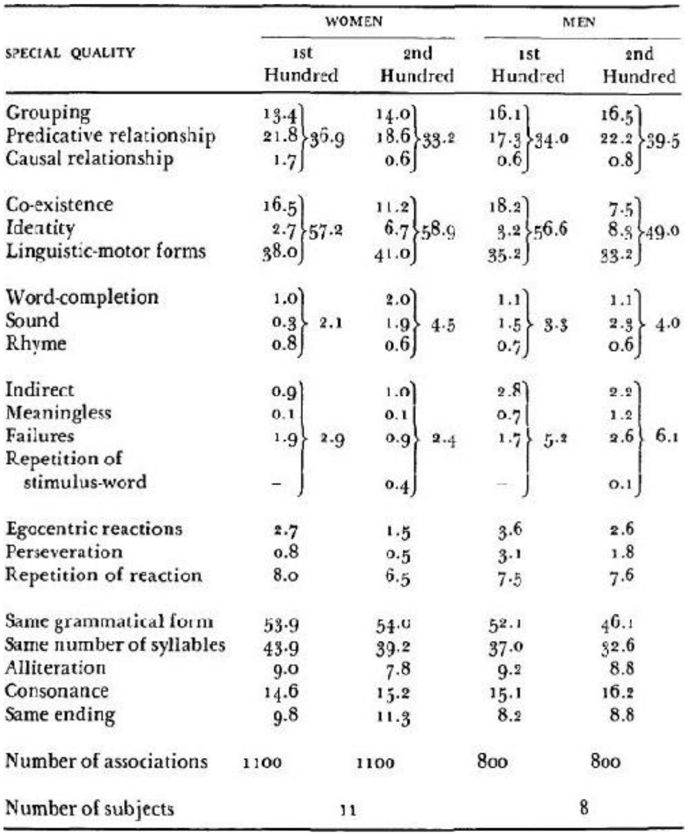
A. The First and Second Hundred of Normal Associations:



SPECIAL QUALITY	WOMEN				MEN			
	1st Hundred		2nd Hundred		1st Hundred		2nd Hundred	
Grouping	24.2	44.0	26.2	49.3	25.2	41.7	21.5	39.4
Predicative relationship	18.8		22.0		15.4		16.8	
Causal relationship	1.0		1.1		1.1		1.1	
Co-existence	27.2	52.8	13.6	46.1	21.7	55.7	13.0	55.7
Identity	3.3		6.8		7.8		12.2	
Linguistic-motor forms	22.3		25.7		26.2		30.5	
Word-completion	0.2	0.3	0.0	1.4	–	0.7	–	0.6
Sound	–		0.3		0.7		0.5	
Rhyme	0.1		0.6		–		0.1	
Indirect	0.6	2.1	0.8	2.6	0.5	1.4	1.2	3.6
Meaningless	0.3		0.2		0.1		0.2	
Failures	1.2		1.6		0.8		2.2	
Repetition of stimulus-word	–		–		–		–	
Egocentric reactions	0.8		0.8		2.0		1.5	
Perseveration	1.5		0.6		1.0		0.4	
Repetition of reaction	10.2		8.8		14.1		10.5	
Same grammatical form	63.2		54.7		60.1		58.4	
Same number of syllables	49.9		42.2		41.1		37.0	
Alliteration	10.2		8.7		9.0		9.0	
Consonance	12.3		12.2		11.1		14.0	
Same ending	11.7		11.0		16.4		16.2	
Number of associations	800		800		700		700	
Number of subjects			8				7	

[398] With the educated subjects, in the first place one is struck by the generally blunter reaction-type. The subjects are nearly all highly educated people: the women too, with few exceptions, are of a high level of education.

B. The First and Second Hundred of Normal Associations:



SPECIAL QUALITY	WOMEN				MEN			
	1st Hundred		2nd Hundred		1st Hundred		2nd Hundred	
Grouping	13.4	36.9	14.0	33.2	16.1	34.0	16.5	39.5
Predicative relationship	21.8		18.6		17.3		22.2	
Causal relationship	1.7		0.6		0.6		0.8	
Co-existence	16.5	57.2	11.2	58.9	18.2	56.6	7.5	49.0
Identity	2.7		6.7		3.2		8.3	
Linguistic-motor forms	38.0		41.0		35.2		33.2	
Word-completion	1.0	2.1	2.0	4.5	1.1	3.3	1.1	4.0
Sound	0.3		1.9		1.5		2.3	
Rhyme	0.8		0.6		0.7		0.6	
Indirect	0.9	2.9	1.0	2.4	2.8	5.2	2.2	6.1
Meaningless	0.1		0.1		0.7		1.2	
Failures	1.9		0.9		1.7		2.6	
Repetition of stimulus-word	–		0.4		–		0.1	
Egocentric reactions	2.7		1.5		3.6		2.6	
Perseveration	0.8		0.5		3.1		1.8	
Repetition of reaction	8.0		6.5		7.5		7.6	
Same grammatical form	53.9		54.0		52.1		46.1	
Same number of syllables	43.9		39.2		37.0		32.6	
Alliteration	9.0		7.8		9.2		8.8	
Consonance	14.6		15.2		15.1		16.2	
Same ending	9.8		11.3		8.2		8.8	
Number of associations	1100		1100		800		800	
Number of subjects	11				8			

[399] The difference between male and female subjects is not considerable in the first three groups, with the exception of a slight preponderance of internal associations in the men (in which groupings particularly play a part). On the other hand, considerable differences appear in the residual group, in which the high figures for indirect associations in the men are particularly striking, being more than twice those of the women. The average of sound reactions in the men is somewhat higher than in the women. The inverse relationship of indirect association and sound reactions, which was previously suspected, is indicated here too:

	WOMEN		MEN	
	1st hundred	2nd hundred	1st hundred	2nd hundred
Sound reactions	2.9	2.4	5.2	6.1
Indirect association	0.9	1.0	2.8	2.2

We shall discuss this phenomenon in the discussion of distraction averages.

[400] Here also the egocentric reactions of the men exceed those of the women. The number of perseverations corresponds to that of egocentric reactions, as in the uneducated subjects—a further proof of the largely affective nature of perseverations (N.B. only in the experiments under normal conditions).

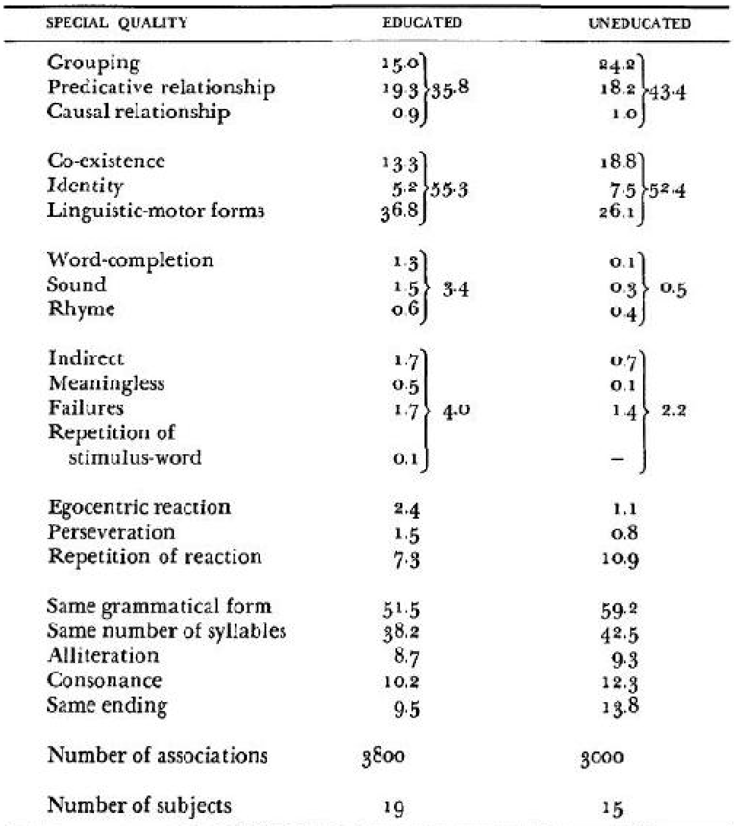
[401] The difference between educated and uneducated subjects can be best made clear by putting the average figures of both groups side by side (Table C).

[402] The educated subjects show a clearly blunter reaction-type than the uneducated. The difference is best expressed by stating: In contrast to the uneducated subjects the educated subjects show a distraction phenomenon.

[403] If we suppose the figures for the uneducated subjects are those of a subject under normal conditions, then the figures for the educated subjects bear the same relation to them as those of a distraction experiment. The sound reactions and the figures for the residual group are proportionately increased, as we have repeatedly seen in the individual accounts.

[404] What is the origin of this difference? One cannot assume that the educated subjects in effect think more “bluntly” than the uneducated; that would be nonsense. One can merely assume that in the experiment they thought more “bluntly” than the uneducated subjects. This appears to us really to be the case, and it seems that from this the explanation of the reaction-type can be deduced.

C. Averages for Educated and Uneducated Subjects



SPECIAL QUALITY	EDUCATED		UNEDUCATED	
Grouping	15.0	35.8	24.2	43.4
Predicative relationship	19.3		18.2	
Causal relationship	0.9		1.0	
Co-existence	13.3	55.3	18.8	52.4
Identity	5.2		7.5	
Linguistic-motor forms	36.8		26.1	
Word-completion	1.3	3.4	0.1	0.5
Sound	1.5		0.3	
Rhyme	0.6		0.4	
Indirect	1.7	4.0	0.7	2.2
Meaningless	0.5		0.1	
Failures	1.7		1.4	
Repetition of stimulus-word	0.1		–	
Egocentric reaction	2.4		1.1	
Perseveration	1.5		0.8	
Repetition of reaction	7.3		10.9	
Same grammatical form	51.5		59.2	
Same number of syllables	38.2		42.5	
Alliteration	8.7		9.3	
Consonance	10.2		12.3	
Same ending	9.5		13.8	
Number of associations	3800		3000	
Number of subjects	19		15	

[405] As proof for this assumption the following points may be considered:

(1) The agreement in grammatical form and number of syllables of the stimulus-word and reaction is clearly higher in the uneducated subjects. This fact seems to

indicate that the uneducated subject sticks more closely to the stimulus-word or is more influenced by it than the educated subject.

(2) The number of meaningless reactions is considerably smaller in the uneducated subject. He has better control over himself or he pays more attention to his reaction.

(3) The uneducated subject surpasses the educated mainly in the number of groupings: i.e., he makes a greater effort to do justice to the meaning of the stimulus-word than the educated subject does.

(4) The uneducated subject surpasses the educated in the number of co-existences, which are mainly made up of spatial concepts, i.e., the uneducated subject makes an effort to imagine clearly the object named by the stimulus-word, and he naturally must associate that which is co-existent with it. The educated subject, on the other hand, has fewer co-existences, as he limits himself to connecting linguistic forms.

(5) The uneducated subject has roughly half as many egocentric reactions as the educated. This fact indicates that he lets himself go much less and exposes undisguised subjective wishes and valuations much less. He makes an effort to achieve as objective as possible an interpretation of the stimulus-word.

(6) One of the main proofs is the almost sevenfold greater number of sound reactions in educated subjects. In this laziness is most clearly revealed. The subject who is intensely attentive produces practically no sound associations.[37]

[406] For these reasons we regard it as proved that the difference between educated and uneducated reaction-types, as far as it is expressed in these figures, is merely a functional one and only has the significance of an attention phenomenon.

[407] If we may estimate the degree of attention from the figures for sound reactions, the residual group and the linguistic-motor forms, then the uneducated women achieve the highest degree of attention and the educated men the lowest. This fact becomes evident if we examine the groups divided according to sex with respect to these points of view.

[408] What is the origin of this difference of attention[38] between educated and uneducated subjects? Various factors must be considered:

(1) The uneducated subject is unused to an experiment of this kind. Naturally, it seems stranger and more difficult to him than to the educated subject, who is much more capable of understanding the significance of the experiment and who must from the first feel more at home than the uneducated in an intellectual activity. The stimulation of the uneducated subject by the experiment is therefore greater and more general, which is why more effort is made in reacting.

(2) Words without any sentence connection are called out to the subject. Under normal circumstances, if one calls anything out to someone it is, as a rule, a command or a question. The uneducated subject, in contrast to the educated, is not used to dealing with individual words outside the sentence connection, particularly if he has never learned a foreign language from books. Thus the stimulus-word contains something strange for the uneducated subject. Under the influence of habit he interprets it instinctively as a question, with the intensity of attention necessary for producing an appropriate answer. The stimulus-word is mostly something to the uneducated subject for which he constructs for himself some interrogative connection, to which he then replies.[39]

(3) The uneducated subject knows words only, so to speak, related to a sentence, particularly when they appear as an auditory phenomenon. In the context of a sentence the words always have a meaning; the uneducated subject therefore knows the word less as mere "word" or verbal sign but much more as meaning. Therefore the uneducated subject grasps the semantic value of a single word only in a fictitious sentence-context, while to the educated the stimulus-word usually remains merely "word" without specific semantic value.[40]

[409] Summarizing, we can say that the uneducated subject shows, in keeping with his lower degree of education, a narrower interpretation of the experiment, particularly of the stimulus-word called out to him, than the educated subject whose approach to the matter is much cooler and more businesslike. In other words: the uneducated subject shows a certain tendency to assimilate the stimulus-word in the form of a question, because it is most usual for called-out verbal sounds to have the connotation of questions.

[410] This attitude to the stimulus-word becomes more evident in certain pathological cases, where the association experiment is nothing but a 2 × 200 sentence-long conversation on a feeling-toned theme. From these observations one can readily deduce that the uneducated subject pays greater attention because the meaning of the stimulus-word influences him more than it does the educated subject.

[411] The difference between educated and uneducated subjects is in the contrast of their interpretations of the stimulus-word. This principle of differentiation allows us to discern two groups, even if vaguely delineated. This distinction, however, is such a general one that it does not take into account other essential differences in the reaction-types. We have therefore made an effort to find other more subtle principles of classification. We asked ourselves whether there are other general factors that influence the reaction, apart from the attention phenomenon.

[412] One principal factor is the individual character. The difference in interpretation discussed above is an intellectual or associative disposition, which may be the same

in individuals of widely varying character. As regards characters, the state of affairs is different. From our experiments two easily recognizable types emerge:

(1) A type in whose reactions subjective, often feeling-toned experiences are used.

(2) A type whose reactions show an objective, impersonal tone.

[413] The former type exhibits reminiscences of a personal kind that often show a very strong feeling-tone. The latter type couples words with words and concepts with concepts, but the personal plays a quite subordinate role in the reaction. This type can be called objective.

[414] The first type can be divided into three groups.

(α) The stimulus-image emanating from the stimulus-word acts principally through its feeling-tone. Usually the feeling-tone of the stimulus-image excites a whole complex of memories belonging to it. The reaction then is inherent in the constellation of this complex. In practice a subject of this type, at least in an extreme case, can easily be distinguished from the others. We call this type the complex-constellation type.

(*β*) The image evoked by the stimulus-word is a personal memory usually taken from everyday life. The reaction contains this image or is at least distinctly constellated by it. We call this type the simple constellation type.[41]

(*γ*) The image evoked by the stimulus-word acts through one or other of its associated attributes (partly the sensory aspects of the image, partly feeling-tones). Presumably the stimulus-image appears in strong relief; now one, now another characteristic comes to the fore and thus, in conjunction with other features, determines the reaction; thus it usually contains a predicate of the object designated by the stimulus-word. We call this type the predicate type.

[415] The common factor in the types described under (α), (*β*), and (γ), as opposed to the objective type (2), is a marked stress of that part of the reaction that is individual, personal, and independent of the stimulus-word. Thus we can say that the difference between type 1 and type 2 is the egocentricity of attitude.

[416] The points presented make clear the general psychological laws that rule our experiment. This does not by any means reveal all the roots from which complications in the reactions originate.

[417] As regards the egocentric attitude, we have tacitly presupposed that the reaction is a more or less clear symbol of internal processes. As long as we know that the subject is speaking freely we can let this assumption prevail *cum grano salis*. The picture of reactions, however, changes at once when the egocentric attitude conduces to feeling-toned complexes, which the subject does not wish to betray.[42] This occurs

particularly in the complex-constellation type. For instance, the stimulus-word raises the complex of an unhappy love that is being kept as secret as possible. If the subject reacted according to his internal images, then he would exteriorize that part of the complex in the reaction through which it could be betrayed. The concealing of an emotion is always characterized by a quite particular attitude, a particular state of feeling. Without conscious censure, the emerging part of the complex is suppressed by the feeling of being directed not to betray, which is present in consciousness and from which specially attuned inhibitions arise. Of course the process of suppression may take place at a considerably more conscious level (or more unconscious, as in hysteria!). Instead of the suppressed complex-image another association fitting in with the feeling of being directed is put in its place and exteriorized.

[418] Thus the true inner association is concealed and the secret kept. It may be extraordinarily difficult for the experimenter, who does not enjoy the complete confidence of the subject, to decide in certain cases whether anything was concealed or not. The decision may perhaps be impossible with people who are capable of controlling themselves to a high degree. In most cases, however, the subjects betray themselves after a short time. According to the laws discussed previously, there must be certain phenomena that betray the suppressed complex. We shall here disregard the lengthening of reaction-time,[43] which occurs with great regularity.

[419] The suppression is betrayed:

(1) By an unusual and suspicious phrasing of the reaction that cannot be explained by the stimulus-word alone, but the peculiar character of which is bound to have been constellated by an X. Occasionally this X can be deduced directly from the peculiarly forced character of the reaction. Such reactions frequently occur in the form of sentences.

(2) By the attention phenomenon. A subject who interprets the stimulus-word as a question and therefore produces a series of highly potent associations suddenly, in the absence of external disturbance, reacts with a sound or some other strikingly superficial association. This result is suspicious; an internal disturbance or an internal distraction must have occurred. The subject may give no information. With a similar stimulus-word the phenomenon is repeated. We are now practically sure that there is something behind this. This suspicion has never proved unjustified. A complex has suddenly emerged, has attracted some of the attention to itself; meanwhile the reaction is produced and, owing to the disturbance of attention, it can be only a superficial one.

(3) By a failure. The emerging complex absorbs all attention so that the reaction either is forgotten or, owing to the absence of all associations, cannot take place.

(4) By perseveration. In this case the critical reaction may be quite unobtrusive but the subsequent one has an abnormal character, in which the preceding reaction takes over the role of the constellation X. The perseverating factor is the emotion stimulated by the preceding association.[44]

(5) By assimilation of the stimulus-word. The stimulus-word is interpreted for no apparent reason in a particular, rare sense or is misunderstood in a striking way according to a feeling-toned conscious idea.[45]

[420] The above points are the main criteria of a concealed complex.[46]

[421] We have purposely devoted so much attention to the discussion of these subtler psychological phenomena because the affective processes, the traces of which we pursued with the greatest possible care in normal reactions, play the most prominent role in the pathological reactions, as we shall show in detail later. What might perhaps be put to one side as a subtlety in a normal reaction will be revealed as the most significant factor in a pathological reaction. For the present we place great value on the realization that the reactions are an extraordinarily sensitive test for affective processes in particular and the individual response of the subject in general.

[422] To illustrate our discussion we present associations of the six main types [1 (a), (b); 2 (a), (b-i), (b-ii), (c)].

1. OBJECTIVE TYPE

[423] (a) Reactions of a subject whose attitude is essentially objective. At the same time the interpretation of the stimulus-word as a question is in the background. There is a tendency merely to put words next to each other, partly in accordance with the law of similarity, partly according to current verbal connections (subject 15, educated men).

Christmas	Easter
Sunday	Monday
winter	spring
lake (or sea)	ocean
pupil	teacher
father	mother
table	leg
head	scarf
ink	pen
needle	holder
bread	to earn
lamp	shade
tree	clearing

mountain	green
dream (*Traum*)	froth (*Schaum*)
exercise-book	knife
paper	cutter
book	to read
school	to attend
to sing	to write
bad	naughty
to clap	hands
year	month
to threaten	fist
long	narrow
rich	poor
suffering	joy
eye	tooth
youth	game
inn	At the Sign of the Bloody Bone
family	scandal
misery	sorrow
to pay attention	to note
fist (*Faust*)	Goethe
people	rebellion
murderer	blood
everywhere	I am at home
to calculate	to measure
to kiss	mouth
ripe	fruit
bond	of love
ground	found
play	of waves
journey	to Canossa
to quarrel	fight
blue	red
flower	calyx
cherry	stone
institution	male nurse
piano	to play

oven	town[47]
to walk	to go
to cook	to eat
water	to drink
to dance	music
cat	mouse
dozen	by the (dozen)
to surmise	W (name of acquaintance who formulated a certain hypothesis)
head	blood and wounds
at home	it’s nice
hedge	rose
indolent	lazy
vinegar	sour
hot	cold
ring	finger
tooth	time
window	frame
frog	leg
sweet	sour
to ride	to travel
friendly	painful
to cut	knife
crown	realm
rough	-ian (ruffian)
prison	detention
to part (*scheiden*)	to avoid (*meiden*)
ill	weak
air	song
potato	to salt
to be lazy	armchair
coffee	to drink
sacrifice	to bring
wedding	feast
grandmother	father
dark	light
heart (*Herz*)	pain (*Schmerz*)
bird	nest
white	black

game	card
Kaiser	Wilhelm
moon	light
to beat	to throw
to light	house
star	shooting
to stroke	cat
grand	magnificent
child	dog
sofa	to lie
wild	animal
tears	to shed
loyalty	German
once (*einmal*)	never (*keinmal*)
wonder	of wonders
blood	vengeance
wreath	athlete
to choose	choice
right	might
to have to	no man must have to[48]
hope	does not let one perish
small (*klein*)	my (*mein*)
unjust	faithlessness
world (*Welt*)	pain (*Schmerz*)
strange	unknown
slate-pencil	to write
to growl	dog
knob	-stick
fruit	to eat
false	fox
helmet	ornament
hay	straw
cleanly (*reinlich*)	painfully (*peinlich*)
trap (*Falle*)	rope (*Strick*) (*Fallstrick*, ‘snare’)
to be revolted	gruesome
resin	to stick

neck	to wring
steep	mountain
swing	to swing
to fetch	to bring
skull	formation
to use	to be able to
stamp	*timbre*

[424] The subject is a doctor, as several technical medical terms, such as *needle-holder* and *skall-formation*, indicate. We do not include those reactions constellated by the profession in the "constellations" in the narrower sense in which we interpret these. Such reactions are not subjective; they belong not only to the individual, but more or less to a whole profession. The only subjective constellation is *to surmise / W*.

[425] (b) Reactions of a subject whose approach is objective and to whom the meaning of the stimulus-word is much more important than to the preceding subject. The tendency is to give as correct a reaction as possible (subject 27, group of uneducated women):

table	chair
head	arm
ink	pen
needle	thread
bread	cheese
lamp	candle
tree	bush
mountain	valley
hair	thread
wood	coal
salt	flour
dream	sleep
exercise-book	book
paper	material
book	newspaper
school	church
to swim	to go
game	to sing
Kaiser	king
moon	stars
to beat	to bite
obstinate	gentle
to light	to extinguish
star	sun

to stroke	to beat
great	wonderful
child	woman
to ride	to travel
friendly	cross
file	hammer
crown	helmet
to paint	oil
thanks	you’re welcome
rough	fine
to stink	to taste
prison	dungeon
to separate	to join
ill	healthy
potato	bread
trap	to catch
to disgust	to taste
to be lazy	to work
coffee	milk
victim	saviour
wedding	funeral
angry	satisfied
soldier	civilian
to clap	to sing
to threaten	to beat
behaviour	polite
to fall	level
to suffer	healthy
youth	age
inn	hotel
family	husband
to pay attention	to hear
fist	hand
to sing	to rejoice
hoop	ring
tooth	mouth
window	floor
frog	stork
flower	grass
cherry	peach

institution	school
piano	violin
fern	rose-bush
to walk	to jump
water	wine
to dance	to sing
dozen	ten
heart	warm
bird	cat
people	household (*family* is implied)
murderer	robber
everywhere	here
to kiss	to flatter
bad	good
ripe	bitter (*sweet* is implied)
band	material
ground	floor
walk	to jump
to quarrel	to make it up
sofa	chair
to love	to hate
wild	tame
tears	to laugh
to spare	better
wonder	nature
blood	human being
wreath	flowers
to choose	to meet
right	wrong
force	voluntary
revenge	peace
hope	joy
to pray	to believe
freedom	imprisoned
world	nation
strange	at home
to growl	to bite
knot	rope

false	true
helmet	sword
plate	tray
hay	grass
pure	clean
to surmise	to doubt
head	arm
at home	away
vinegar	wine
resin	pitch
swing	to throw

[426] The subject is a nurse from our hospital. Subjective factors are entirely absent from the reactions. Her manner is extraordinarily objective and calm. In contrast to the preceding subject it must be noted that here the meaning of the stimulus-word is the decisive factor, which is expressed in many contrasting ways.

[2]. EGOCENTRIC ATTITUDE

(*a*) *Simple-constellation type*

[427] Reactions of a subject in whose reactions numerous subjective experiences are used. The attitude is egocentric in so far as subjective memories prevail (subject 18, educated men).

father	anxious (the subject is the father of a new-born child)
head	round
ink	sour (*red/litmus* is implied)
bread	bread-factory
lamp	smells
tree	F. (name of an acquaintance connected with a certain experience)
mountain (*Berg*)	Ütliberg
hair	falling out
salt	Rheinfelden (where there are salt works)
wood	ebony
dream	R. (name of a colleague who was occupied with dream-analyses at this time
paper	fraud (paper in the sense of documents in evidence about a case of fraud)
book	letter (*Buch-stabe*, ‘letter of the alphabet’)
pencil	Kohinoor (the subject uses this brand)

school	S. (name of the place where the subject went to school)
liberty	statue (the subject had been in America and particularly admired New York)
unjust	to imprison (constellation from daily intercourse with querulous patients)
to be lazy	wonderful
coffee	Mocha
sacrifice	L. (name of an ailing painter who had a predilection for painting sacrificial scenes)
wedding	without alcohol (the subject is a teetotaller)
grand-mother	dead
wicked	R. (name of a patient with a moral defect)
to need	B. (name of a colleague)
year	and day
to threaten	threatener (*Drohweber*, nickname of a patient who frequently uttered threats)
sour	dough (*Teig*)
(*saner*)	(*Sauerteig*, ‘dough’)
youth	Munich (newspaper *Youth*)
family	day
sorrow	sorrowful
to pay attention	association-experiment (momentary constellation
nature	R. (name of a patient)
folk	*Folk-Psychology* by Wundt (a work that had recently been ordered by the hospital)
murderer	G. (name of a murderer who was just then in the hospital for examination)
everywhere	superman
(*überall*)	(*Übermensch*)
to calculate	slide-rule
wild	dentist (“Wild” is the name of a dentist)
tears	vale
war	turmoil
faithful	little dog
once	shorthand again (see above)
miracle	Lourdes
blood	English (in England the word must not be said)
right	and duty
ground	and soil
game (*Spiel*)	thing (*Zeug) (Spielzeug, ‘toy’*)
arm	W. (name of a patient who had injured his

	arm)
blue	Grotto in Capri
strange	stranger
to growl	bulldog
knot	East Swiss (memory of his student years)
fruit	to steal
false	trap
helmet	house (Helmhaus, a public building in Zurich)
misery	hunger
hay (*heu*)	Heustrich (name of a spa)
raspberry	park (the raspberries in the hospital garden)
to sing	Miss B. (name of a singer who was at the hospital just at that time)
ring	hospital gardens (a ring was at that time found in the garden of the hospital)
tooth (*Zahn*)	Göschenen (the writer, Zahn, lives in Göschenen)
window	opening
frog	tree-frog
flower	rose
cherry	juicy
hospital	R. (a certain hospital for feeble-minded children)
male nurse	B. (name of a particular nurse)
fern	tape-worm
to be obliged to	Lessing (a famous quotation from Lessing is implied)
oven	Pest[49]
revenge	thirst
hope	pregnancy (this constellation is explained by earlier comments)
small (*Klein*)	male nurse (Klein is the name of a nurse)
to pray	church
row	M. (name of someone who had made a joke referring to the word “row”)
to walk	L. (name of patient who often went for walks)
to cook	cooking lessons
water	supply
to dance	concert-hall (the hall in which the dances at the hospital are held)
dark	room (the subject is an enthusiastic amateur photographer)

heart	failure
bird	paws (*claws* is to be interpolated)
to swim	L. (name of a patient who often used the swimming pool)
white (*Weiss*)	malaria (a patient named Weiss suffered from malaria)
game	Halma (which was at that time played in the wards)
thirteen	shorthand (*to write* is to be interpolated; the subject was keenly occupied with shorthand)
sofa	cushion
thousand	Basel (a student friend of subject from Basel went under the name of “Tausig,” the dialect form of *tausend* (thousand). The stimulus-word was of course called out in standard German but assimilated in the dialect form by the subject
to love	ball
son	sonny (the subject is the father of a new-born son)
at home (*daheim*)	newspaper (called *Daheim*)
vinegar	home-made
trap	mousetrap
throat	epiglottis
to strike	(name of a doctor who had been struck by a patient)
star	C. (Stern, ‘stern,” is the name of a patient in Ward C)
to stroke	kitten
grand (*grossartig*)	Grossman (name of patient who was included merely as a sound-association)
sweet	bananas (cf. the reaction *wood/ebony*. The subject had recently given some lectures on travels in Africa)
friendly	H. (name of an acquaintance)
to float	S. (name of a famous airman)
skull	occiput
rough (*rau*)	A. 1 (Rau is the name of a patient in Ward A.1)
to report	male nurse
prison	police-barracks (the police in Zurich)
to separate	sulphuric acid
ill	diabetes

[428] This type is characterized by the emergence of numerous subjective experiences, mostly of recent origin and belonging for the most part to the field of everyday activities. It goes without saying that, in spite of the objective character of the constellations, some also occur that belong to a feeling-toned complex. These are, however, relatively rare in comparison with the others and are in some cases well concealed. The recently experienced joy of fatherhood has an after-effect in several reactions: *father / anxious, hope / pregnancy, son / sonny*. This feeling-toned diminutive seems to us echoed in the somewhat striking reactions: *to stroke / kitten, fidelity / little dog*.

(*b*) *Complex-constellation type*

[429] (i) Reactions of a subject in whose reactions a feeling-toned complex appears quite openly. The meaning of the stimulus-word is brought into relation with the complex (subject 21, educated men).

wood	pile
dream	studies (simple constellation)
exercise-book	pen
paper	line
pencil	big
school	bank
to sing	choir
ring	on the finger
tooth	teeth
window	frame
frog	hops
flower	stem[50]
hospital	big
piano	I cannot play
male nurse	B. (name of a certain male nurse)
stove	wood
to walk	a long way
to dance	hotel F. (a certain hotel where there was dancing)
dark	room
heart	red
bird	feathers
to swim	movement
game	children
Kaiser	Wilhelm

to hit	to beat	
to set fire to	S. (name of an incendiary)	
star (*Stern*)	Miss Stern (an actual person)	
grand	ah!	
child	children	
dark red	again ah!	
to ride	riding track	
murderer	in C (a certain insane murderer in Ward C in the hospital)	
everywhere	K. is (the name of a mobile catatonic)	
to calculate	I cannot	
to kiss	again and again	complex of a romance recently terminated
natural	wonderful	
bad	no	
time	not now	
ripe	I am for it	
row	soldiers	
ground	and soil	
game	child	
poor	poor as a beggar	
to quarrel	oh rot!	
sofa	is soft to sit on	
to love	ah!	
son	son and father (the subject had had unpleasant quarrels with his family on account of his romance)	
wild	mother (*wild* = angry; *wild* is here assimilated into the complex in the special sense of the dialect expression)	
tears	she has now (that is, the abandoned sweetheart)	
protection	I cannot offer her	
war	if there only were	
faith	I have not kept	
once	and never again	
friendly	very nice	
crown	queen	
rough	table	
to stink	pooh!	
shrill	hurt	
to separate	W. (name of a mental patient whose marriage ended in divorce)	

potato	broth
to be lazy	nice
cross	I am not
come	with me to the theatre X (a certain theatre)
year	1904
family	V. (subject’s own family)
to take care	I should
finally	it will end
folk	worth much
slate-pencil	she is a teacher
to growl	poodle
knob	knob-stick
false	blonde (a “lady,” who is false and blonde, to be interpolated)
helmet	fire brigade
clothes	woman’s skirt
softly	she comes along
gallantly	up the stairs
plate	on the table
misery	she cries
hay	in it lies a farmer
raspberry	in the wood
at home	in D. (home of the sweetheart)
wonder (miracle)	would have to happen
blood	she is anaemic
wreath	on the coffin
to choose	another
to part	I need not
right	she is not
to have to	I do not have to
force	I do not use on her
revenge	oh no!
hope	I do not know
small	oh no!
to pray	perhaps
dear	she was to me
wool	a woman’s dress
old	perhaps
freedom	she could have
unjust	I was not
world	wide

strange	that she is now
hedge	fence
lazy	sometimes (i.e., sometimes she is lazy)
to woo	a woman
hot	love
consciousness	yes, in the focus of consciousness
vinegar	sour
trap	into it
to disgust	yes, so-so
riot	there is therefore none
resin	hair
(*Harz*)	(*Haare*)
to dress up	yes, fine and gallant
omen	bad

[430] A strong feeling-toned complex is characteristic of this mode of reaction. The stimulus-word is assimilated as a question; the experiment therefore bears the imprint of a conversation in which the subject has only a rather dim awareness of the current situation. This explains the somewhat abnormal character of a conversation of this type. The mode of reaction can be explained by a very strong psychological sensitivity. The relatively numerous interjections and the egocentric references, not only within the complex, also point towards this. The subject's egocentricity emerges clearly throughout. He is mentally entirely sound and would at other times probably have presented a much more objective type. The abnormal character of the reaction is to be attributed merely to the temporary but prevailing emotion. One could generalize and say that this abnormal state, caused by the affect, is the prototype of the hysterical reaction.

[431] (ii) Subject 24 of the group of uneducated women is a good example of a complex appearing in a disguised form. We refer to the associations already given in detail in the relevant section.

(c) Predicate type

[432] Reactions of a subject who judges the object of the stimulus-word from a personal point of view (subject 7, educated women

lake	beautiful nature
schoolboy	diligent
father	something wonderful, good, holy
needle	work
bread	best food
lamp	work

tree	something beautiful
mountain	terrible, climbing is nicer
hair	head-dress
salt	strengthens food
wood	fire
dream	many experiences
exercise-book	much work for the children
paper	blessed, because we write on it
book	joy
school	joy
dozen	straight, order
dark	horrible
heart	beats
bird	lovely, to fly
to swim	lovely
white	hard, bright
game	to enjoy
thirteen	clumsy
friendly	duty
crown	unnecessary
rough	weather
moon	beautiful
to beat	unnecessary
to light	an art, till one managed it
to sing	beautiful
ring	something silly
tooth	glad not to have any more
frog	something unnecessary
flower	joy
cherry	good fruit
hospital	narrow
piano	mainly laborious
male nurse	respect
fern	beautiful wood
stove	lovely in cold winter
to walk	one sometimes must
to cook	laborious
water	lovely
to dance	gladly when one is young

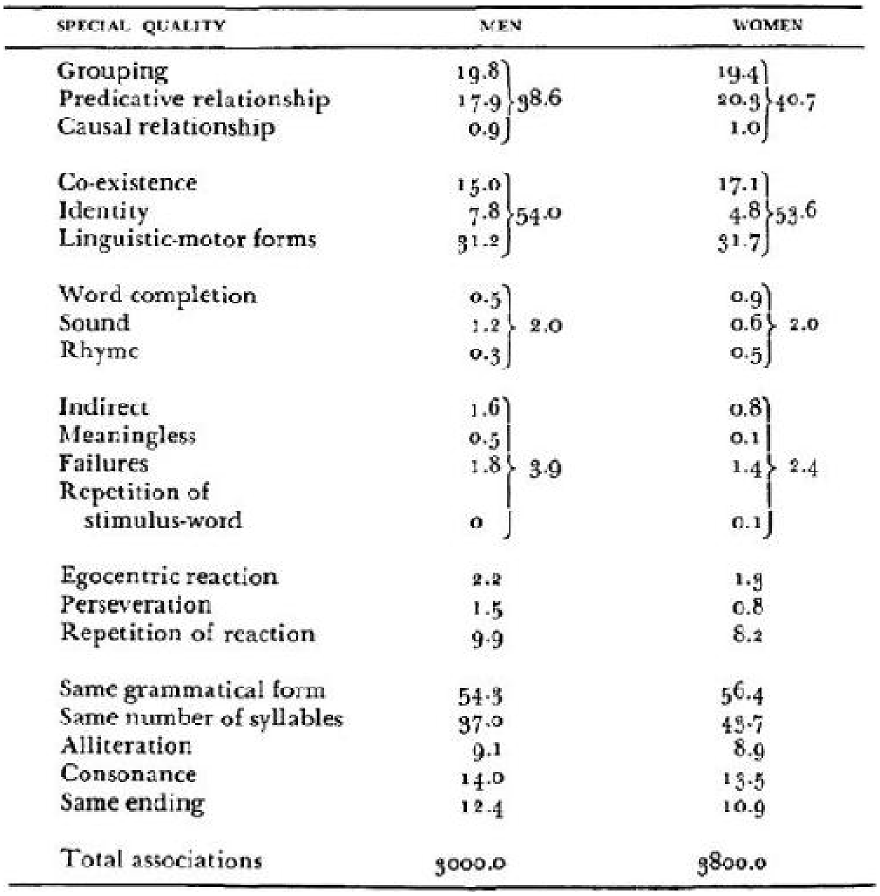
cat	sneak
star	magnificent
grand	pompous
child	gift of God
sweet	pleasant
to ride	dangerous
to stink	sometimes, alley
shrill	to hurt
ill	to hurt

[433] The characteristic of this mode of reaction is an unusually strong personal participation, which leads to a constant evaluation of the object, usually with reference to herself.

II. Sex Differences in the Experiment under Normal Conditions

[434] We have considered our individual figures from the point of view of the sex difference and calculated their averages (see Table D).

D. Sex Differences in the Experiment under Normal Conditions



SPECIAL QUALITY	MEN		WOMEN	
Grouping	19.8	38.6	19.4	40.7
Predicative relationship	17.9		20.3	
Causal relationship	0.9		1.0	
Co-existence	15.0	54.0	17.1	53.6
Identity	7.8		4.8	
Linguistic-motor forms	31.2		31.7	
Word completion	0.5	2.0	0.9	2.0
Sound	1.2		0.6	
Rhyme	0.3		0.5	
Indirect	1.6	3.9	0.8	2.4
Meaningless	0.5		0.1	
Failures	1.8		1.4	
Repetition of stimulus-word	0		0.1	
Egocentric reaction	2.2		1.3	
Perseveration	1.5		0.8	
Repetition of reaction	9.9		8.2	
Same grammatical form	54.3		56.4	
Same number of syllables	37.0		43.7	
Alliteration	9.1		8.9	
Consonance	14.0		13.5	
Same ending	12.4		10.9	
Total associations	3000.0		3800.0	

[435] In considering the figures, one is struck by the slightness of the difference between the two sexes. With few exceptions the figures essentially tally; in any case, the definite numerical differences that separate the group of educated from the uneducated are absent. In the men the type is somewhat blunter than in the women; the men have rather more sound associations, also more indirect associations; these phenomena may be connected with the blunter type. The larger number of egocentric reactions and perseverations seems, according to earlier investigations, to depend on the men's more uninhibited behaviour. The difference in the figures for coincidence of grammatical form and number of syllables is analogous to the corresponding difference between educated and uneducated subjects, and may be attributed to the fact that in our male subjects, particularly in the uneducated ones, the level of education is higher than in the corresponding women subjects. From the figures of the experiment under normal conditions nothing typical of feminine psychology emerges, which does not mean that no differences exist. Our method of investigation is obviously far too crude to discover subtle differences of this sort.

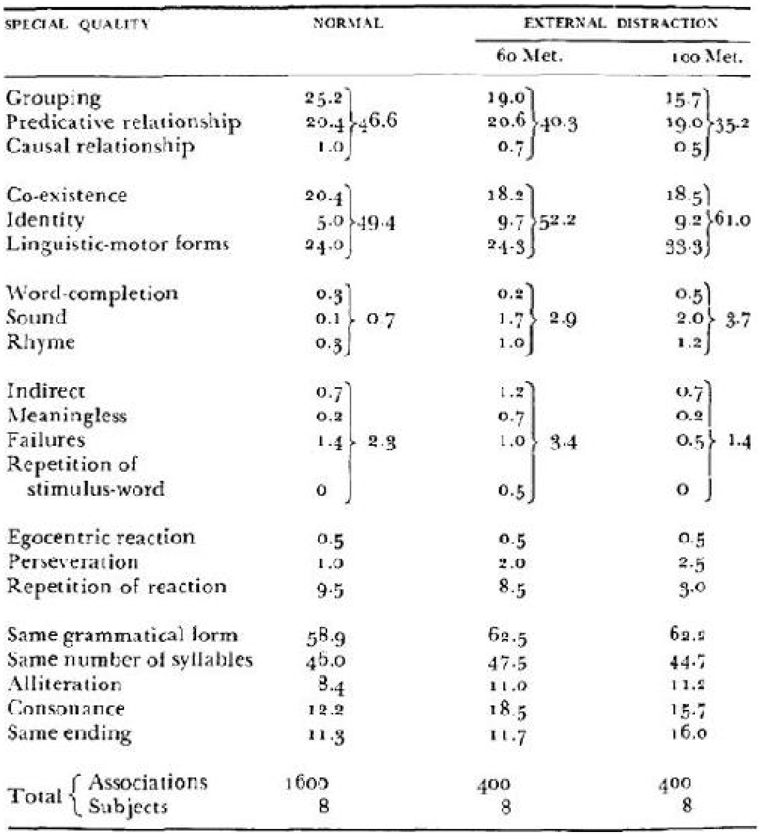
III. Averages of the Distraction Experiments

[436] We give in Tables E and F a compilation of the average figures from the distraction experiments. To facilitate comparison we are putting the average for experiments under normal conditions alongside.

[437] The figures for the distraction experiments show a progressively blunter type of reaction than those obtained under normal conditions. The main difference is quite unequivocal. The internal associations decrease under distraction as opposed to the external associations and sound reactions, both of which increase.

[438] Looking at the figures for internal associations, we see that the women in this group have higher figures than the men. The lowest figures are for men. The objection that the women start with a higher number of internal associations under normal conditions applies only to uneducated women. Educated women show a somewhat blunter reaction-type, under normal conditions, than educated men. The fact that the number of internal associations does not fall as low in women as in men means that the women were less adaptable to the purposes of the experiment than were the men. Comparing the minus differences of the internal associations clearly shows the smaller interest of the women.

E-I. Averages in the Distraction Experiments: Uneducated Women



SPECIAL QUALITY	NORMAL		EXTERNAL DISTRACTION			
			60 Met.		100 Met.	
Grouping	25.2	46.6	19.0	40.3	15.7	35.2
Predicative relationship	20.4		20.6		19.0	
Causal relationship	1.0		0.7		0.5	
Co-existence	20.4	49.4	18.2	52.2	18.5	61.0
Identity	5.0		9.7		9.2	
Linguistic-motor forms	24.0		24.3		33.3	
Word-completion	0.3	0.7	0.2	2.9	0.5	3.7
Sound	0.1		1.7		2.0	
Rhyme	0.3		1.0		1.2	
Indirect	0.7	2.3	1.2	3.4	0.7	1.4
Meaningless	0.2		0.7		0.2	
Failures	1.4		1.0		0.5	
Repetition of stimulus-word	0		0.5		0	
Egocentric reaction	0.5		0.5		0.5	
Perseveration	1.0		2.0		2.5	
Repetition of reaction	9.5		8.5		3.0	
Same grammatical form	58.9		62.5		62.2	
Same number of syllables	45.0		47.5		44.7	
Alliteration	8.4		11.0		11.2	
Consonance	12.2		18.5		15.7	
Same ending	11.3		11.7		16.0	
Total Associations	1600		400		400	
Total Subjects	8		8		8	

[439] The remaining differences are unfortunately not equally apparent, as they are divided into three groups, the content of which is of varying psychological valency. Therefore the number of internal associations is the best simple measure of the degree of distraction. The differences for the men show a certain agreement, while the minus difference of uneducated women is greater than that of educated women, which would indicate better adaptation of the uneducated women to the experiment.

[440] Admittedly the plus differences in the group of sound reactions again show a more significant increase in educated women than in uneducated:

	Uneducated women	Educated wom
Plus difference of sound reactions	2.6	8.3 and 6.4

[441] The cause of this contradiction might be that the educated women's attitude to the experiment was considerably more variable than that of the uneducated female subjects. Both groups carry out the instructions of the experiment, the making of strokes and the simultaneous reaction, with somewhat more difficulty than the men. If one compares, for example, the differences of educated men and women in the internal distraction experiment, one is immediately struck by the more complete effect of distraction in the men. The only essential difference between the two female groups is perhaps that educated women are capable at least at times of dividing their attention.

[442] It seems to us now that we have here a certain difference in the mode of reaction of men and women, a difference that can be determined quantitatively. As, however, with the limited material, sources of error are not excluded, we offer these observations for further discussion.

[443] The figures in the individual groups of the scheme show certain variations that need discussion. While the co-ordinations decrease fairly evenly with distraction, the predicates under distraction present a somewhat different aspect in men and in women.

	EDUCATED	UNEDUCATED
	External Distraction	External Distractio
Women	−0.2	−0.6
Men	−8.5	−4.7

Minus difference of the predicates

[444] The table shows that under distraction the predicates decrease to a lesser degree in women than in men. Here let us remember that in the discussion of the predicate type we stated the hypothesis of the primary, sensory vividness of the stimulus images, which invites predicates. This psychological peculiarity shows itself, of course, in a state of attempted division of attention; this will hinder the experiment in

that, in the absence of active concentration, the primarily vivid images absorb the interest and thereby bar or impede the division of attention as planned in the experiment. We shall see this phenomenon quite clearly in the result of the distraction experiment of the predicate type, to which we are referring. There are relatively very many predicate types among the women, which is probably the reason for the apparent prevalence of the predicate. In contrast to the decrease of internal associations there is an increase of external associations, in so far as this is not influenced by a stronger rise of sound reactions. The three groups do not participate equally in the increase of external associations. We even notice that the number of coexistences shows rather a tendency to decrease. We tabulate the differences again here:

UNEDUCATED		EDUCATED	
Women	Men	Women	Men
−2.0	−1.5	−3.4	−0.4

Difference between normal experiment and distraction with reference to coexistences

[445] They are all, contrary to expectation, minus differences. This shows that the coexistences cannot be held responsible for the increase of external associations. Remembering the discussion where we explained that coexistences frequently arose owing to the effort of vividly imagining the object of the stimulus-word, then the decrease under distraction is comprehensible; coexistence is to some extent a step towards internal association and therefore plays a part in its decrease.

[446] The groups of identities and linguistic-motor forms in general show a rise—which is, however, affected by a big increase of sound reactions, causing, for example, in the group of educated women particularly, a decrease of the two groups. We explain these variations by the irregularity of distraction often mentioned. The quantitatively infrequent occurrence of word-completion in uneducated subjects is striking. We believe that inadequate verbal facility is responsible for this, particularly lack of practice in standard German. Experiments with uneducated Germans, viz., North Germans, might produce different figures. Sound associations are decidedly more frequent in educated subjects than in uneducated.

[447] The indirect associations behave strangely. We have already indicated an inverse relationship of their increase with sound associations. In our averages one is first struck by a dependence on the degree of distraction.

	UNEDUCATED		EDUCATED	
	Women	Men	Women	Men
Normal conditions	0.7	0.8	0.9	2.5
Distraction	0.9	2.4	0.9	4.6

[448] These figures show that uneducated subjects produce fewer indirect associations on the average under normal conditions than do the educated and that women produce fewer than men. Under distraction the women's aversion to indirect associations is shown even more clearly. While a quite definite increase is shown in the men, the average figure for educated women under normal conditions remains the same, and in uneducated women only a quite insignificant increase occurs. Thus, in this respect, a significant difference between the sexes must exist, the nature of which is at present unknown to us. The nature of indirect associations, discussed above (predominantly sound reactions as intermediate links), makes a dependence on distraction readily comprehensible. Thus with the increase of sound reactions we could expect an increase also of indirect associations. For the sake of clarity we briefly repeat the relevant figures here:

	UNEDUCATED				EDUCATED			
	Women		Men		Women		Men	
	S.R.	Ind.	S.R.	Ind.	S.R.	Ind.	S.R.	Ind.
Normal conditions	0.7	0.7	0.6	0.8	3.3	0.9	3.6	2.5
External distraction I	2.9	1.2	3.1	3.4	10.2	1.0	9.6	3.2
External distraction II	3.7	0.7	1.0	1.4	9.2	0.2	8.2	6.2
Internal Distraction (educated subject only)	—	—	—	—	11.6	1.6	20.7	4.5

[449] Although the simultaneous increase of sound reactions and indirect associations under distraction, already mentioned above, is indicated in general in these figures, the parallelism of the two groups is in places somewhat unbelievable. If a parallel between the two groups really exists, one would expect that the maxima of indirect associations would sometimes coincide with the maxima of sound reactions. This is by no means the case. In considering, in the figures for the distraction experiments, the maxima of indirect associations, we see that the maxima only coincide in two cases. No corresponding increases of indirect associations coincide with the maxima of sound reactions. Thus no clear and simple connection in the form of a direct proportion exists. Neither do these figures provide easily recognizable clues to an inverted relationship. Only the group of educated men shows a co-incidence of a striking maximum of indirect associations with the minimum of sound reactions, which is nevertheless a noteworthy fact. In the female groups we see the indirect associations strikingly lagging behind the sound reactions. In the educated men a distinct increase of sound reactions, from 3.6 per cent under normal conditions to 20.7 per cent under distraction, corresponds to an increase of only 2 per cent of indirect associations, while their maximum coincides, as already stated, with a minimum of sound reactions. This aspect of the indirect associations seems to indicate a certain interdependence of the two groups; we see this as an increased

occurrence of indirect associations affecting mainly the group of sound reactions. Taking the group of sound reactions in relation to indirect associations, we get the following picture:

	UNEDUCATED				EDUCATED			
	Women		Men		Women		Men	
	S.R.	Ind.	S.R.	Ind.	S.R.	Ind.	S.R.	In
External distraction I	1.7	1.2	1.4	3.4	5.5	1.0	8.0	3.
External distraction II	2.0	0.7	0.8	1.4	6.5	0.2	3.8	6.

[450] The pure sound associations show, with one exception, inverse relation between the two groups. The choice of sound associations for the purpose of the demonstration is not arbitrary, since they form the main part of the whole sound group; at the same time they are the associations that are suppressed under normal conditions (this does not apply to all rhymes, for example). It is just this fact, that the pure sound associations are repressed under normal conditions, that has the greatest significance for the explanation of the inverse relation. The unspoken and mostly quite unconscious intermediate links between indirect associations are in the majority of cases sound associations. Under normal conditions sound associations are continually opposed by inhibitions, as they are, as a rule, quite inexpedient in respect to the process of association and are therefore excluded. There will always be a certain tendency to suppress the sounds; the slighter the distraction of attention the stronger this tendency will be, but the greater the distraction is, the weaker it will be. With increasing distraction the reaction will be more and more influenced by sound, till finally only a sound is associated. Between the influence of sound and the sound association there comes a point where, although the sound association cannot conquer the inhibition it encounters, it does exclusively affect the sense of the following reaction by interrupting the connection between stimulus-word and reaction; it is immaterial whether the subconscious sound association is formed centripetally or centrifugally. The mediating sound association, which almost reaches the threshold of reaction, leads to the formation of the indirect association. Of course the intermediate links need not necessarily always be sound associations; they need only invite enough inhibition to remain just below the threshold of reaction. Thus we interpret the indirect association as a symptom of repression of inferior associations, which almost reach the threshold of reaction.[51] Using this interpretation the apparently inverse relation of sound association and indirect association can be easily understood: if the sound association predominates, one can conclude from this that the inhibition of sounds has not occurred; therefore repression and consequently indirect association are also prevented. If the number of sound associations decreases it is a sign that inhibition is increasing, thus providing the conditions for the occurrence of indirect associations. The indirect associations are therefore a

transitional phenomenon which reaches an optimum at a certain degree of distraction. This also explains the increase apparently in proportion with the sound reaction and the subsequent decrease in inverse proportion after the critical point has been reached.[52]

[451] Claparède, who has worked on the question of indirect associations from another angle, believes that it is the "résultat du concours de plusieurs associations intermédiaires, chacune trop faible pour être consciente."[53] From the results of experiment we are in complete agreement with this interpretation. The tendency to form a meaningful association, which derives from the stimulus-concept, inhibits sound associations. Both are too weak, however, to produce a reaction. If the sound association, not linked in meaning with the stimulus image, predominates, then the indirect association comes into being; otherwise it is a reaction that, although strongly influenced by sound, is nevertheless meaningful. Piéron's[54] interpretation, which states that the third link of the indirect association has greater interest for the individual than the intermediate link, does not fit in with the results of our experiment. Nevertheless there is something attractive about Piéron's view and it is valid for all those cases where the external stimulus is unconsciously assimilated as a strongly charged complex, dominant in the subject's consciousness. (We shall discuss this further possibility of an indirect association in a later paper.) Piéron's view does not fit in with a vast number of the indirect associations of everyday life. From many examples we mention only one very instructive observation from our own experience.[55] One of the present authors was smoking a cigar; suddenly it occurred to him that he had no more matches on him. He had a longish train journey before him and had put a good Havana cigar in his pocket in order to smoke it on the way. He now thought he would have to light the cigar from the one he was finishing. With that, the narrator was satisfied and dropped the train of thought. For about one minute, he looked out of the window at the landscape, which he observed attentively; suddenly he noticed himself saying involuntarily and quite softly; "Bunau-Varilla." Bunau-Varilla is the name of a well-known Panamanian agitator in Paris. The observer had read the name several days before in the *Matin*. As this name appeared to him to be without any connection with the contents of consciousness, he immediately directed his attention to the name and observed what occurred to him in the process (Freud's method of spontaneous association). Immediately *Varinas* occurred to him, then *Manila*, almost simultaneously also *cigarillo*, and with it a vague feeling of a South American atmosphere; the next clear link was the Havana cigar and with it the memory that this cigar had provided the content of the penultimate thought-cycle. The intermediate links, *Varinas* and *Manila*, are brands of tobacco, both of which had the tone of something Spanish for the narrator; *cigarillo* is the Spanish word for cigarette; the observer had smoked cigarillos with Manila tobacco in a Spanish colony but not in South America. Nevertheless there was a faint

"South American" echo about *cigarillo*. While the observer was looking out of the window he had not the slightest feeling of such a train of thought, his attention was completely concentrated on the landscape. The unconscious train of thought leading to the formation of "Bunau-Varilla" was: *Havana cigar / cigarillo* with Spanish-South American background / a travel memory with *Manila-cigarillo* / Spanish-American brand of tobacco *Varinas / (Varinas* and *Manila* condensed by dream-mechanism into) *Varilla / Bunau-Varilla*. A sufficient reason for the subconscious pursuance of the thought of the cigar was that the observer had prepared himself not to miss lighting the Havana cigar from the end of the cigar still alight. According to Piéron, "Bunau-Varilla" would have to be the emotionally charged final link desired by the observer. This is what in fact it is not; it is merely a product of condensation formed by the competition between several very weak intermediate links (according to Claparède's interpretation). The mechanism is a linguistic-motor automatism such as occurs not infrequently in normal subjects (in certain hysterical subjects, it is true, far more often). The subconscious association-process takes place through similarities of image and sound; in fact all associations taking place in the subconscious, i.e., outside the range of attention, do so (with the exception of certain somnambulant processes). In connection with Jerusalem's[56] communication Wundt[57] calls the intermediate link "unnoticed" in contrast to "unconscious," in which we can perceive not material objection but merely a verbal quibble. It is not surprising that Scripture[58] obtains doubtful results in his experiments on indirect associations, and Smith[59] and Münsterberg[60] obtained no results, because their experiments were set in a way that did not favour the production of indirect associations. The best indirect associations are provided by careful self-observation in everyday life.[61] Indirect verbal associations originate, as our experiment shows, mainly in distraction experiments.

[452] Meaningless reactions show, as is to be expected, an increase under distraction.

[453] The failures, the mainly emotive nature of which has already been frequently stressed in the individual descriptions, are conspicuously absent in the group of educated men under distraction. For the rest they present a constant pattern. We shall return to this group in the discussion of the average of the predicate type.

[454] A state of affairs similar to that of meaningless reactions obtains in the repetition of the stimulus-word; it too increases under distraction.

[455] We have combined the four last-mentioned groups to form the so-called residual group, with the original purpose of collecting the abnormal subsidiary phenomena of the association experiment into this group. From the number of this group we then hoped to obtain a certain co-efficient of the emotional state into which the subject was brought by the experiment. The decision to include the indirect associations also in this group was based on the assumption, in itself not improbable, that in indirect

associations, because of their provenance from sound-shifts, we really have experiments that have failed. Naturally we interpreted the meaningless reactions, as well as the last two groups, as experiments that failed. In this interpretation we were supported by certain experiences in the pathological field—that is, the association phenomena in emotional stupidity,[62] where the figures for this group rise considerably. It is true that the results of our experiments do not confirm the original assumption of the emotional nature of indirect associations. This does not hold in the other three groups. The nature of the emotion, however, must be defined more precisely for these three groups. Meaningless reactions and repeated stimulus-words originate according to our experience as a rule from stupefaction, which is produced by the way the experiment is set, while the majority of failures are based on emotion evoked through the awakening of feeling-toned complexes. Stupefaction, caused by the way the experiment is set, can in that case be completely excluded. The inclusion of failures in the residual group is therefore arguable. We have therefore substituted the non-committal designation "residual group" for "emotion group," the name we originally chose for this group. The summation of the figures for these groups was undertaken for clarity of arrangement, with full realization of its provisional and inadequate nature. Everyone who has done experimental work, particularly with such involved material, knows that one must pay dearly for one's experience and that one knows afterwards what one should have known before.

[456] The distribution under distraction of egocentric reactions (which to some extent represent a pointer to feeling-toned reactions) is best demonstrated by a tabulated survey of the differences from the results under normal conditions.

	UNEDUCATED		EDUCATED	
	Women	Men	Women	M
No. of egocentric reactions under normal conditions	+0.5	+1.7	+2.1	+2
Difference under distraction	0.0	−1.7	−1.0	−1

[457] These differences show that according to our material the minus differences of the men are greater than those of the women; thus that, although women do not betray greater egocentricity under normal conditions than men, they maintain it more firmly under distraction than men do.

[458] With respect to perseverations, we have already several times proved a certain dependence on strong feeling-tones. As regards its frequent increase under distraction, we assumed the cause to be lack of association with distracted attention. Obviously various complicated conditions are involved here which we cannot separate beforehand. The following table of differences from normal conditions shows the effect of distraction on perseverations.

UNEDUCATED	EDUCATED

Women	Men	Women	Men
+1.2	+0.4	+1.1	−0.2

[459] From these figures it appears that in men perseverations decrease under distraction, while in women they increase.

[460] The number of egocentric reactions gives us a rough measure of how many feeling-toned references to the ego occur among the reactions;[63] the number of perseverations indicates something similar to us, but in a less direct form.

[461] As stated above, in women there is less effect of distraction on the reaction. From this one may conclude that female attention with respect to our experiment has proved less easy to divide. The smaller change in the number of egocentric reactions in women may be connected with this. If the number of egocentric reactions shows only a slight tendency to decrease, a similar tendency is to be expected in perseverations. These increase, however. We explain this by the fact that in the associationless vacuum artificially created by distraction feeling-toned contents of consciousness can persist more easily than otherwise. Why women in particular should have the tendency to perseverate under distraction we do not know. Perhaps it is connected with more intense feelings?

[462] That attention cannot easily be divided in women may be based on the following causes:

(1) We have already indicated that various individuals (predicate types) presumably have fundamentally much more vivid inner images than others. By “more vivid images,” we mean such as have combined in themselves a greater intensity of attention or, in other words, such as appear simultaneously with many other associations evoked by them. The larger an association-complex is, the more the “ego-complex” is also involved. It is therefore understandable that with the vividness of the inner images, not only does the number of internal predicates increase but also the number of subjective value judgments generally—that is, of egocentric reactions.

(2) The vividness of the inner image is by no means always a primary involuntary phenomenon but can also be an artificial one; the attention is purposely directed to it or, in other words, numerous new associations accompany an image that appears with few collateral associations. This process is stimulated by the image that appears; it is actually realized through another association-complex, which at the time fills consciousness. The vividness of the inner image is thus in one case primary and involuntary, in the other case secondary and willed. The latter form is then under the influence of another intellectual phenomenon present at the time.

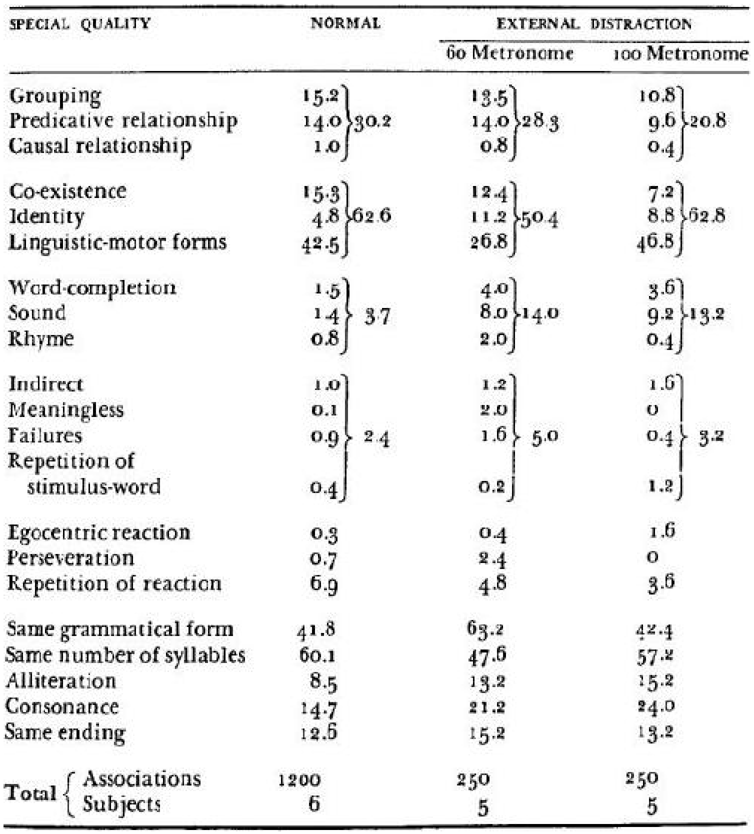
(3) If the inner images are basically very vivid and plastic, i.e., if they occur from the first together with many collateral associations, they must always have a quite

definite effect on attention and therefore make more difficult or hinder its division, according to the degree of vividness. This is, as we shall see, the case with the predicate type.

(4) If the inner images are under the influence of an already existing association-complex, artificially vivid or plastic, it then depends on the stability of this complex whether the dividing of attention will be possible or not.

(5) We have no reason to assume that the inner images are in general fundamentally more vivid in women than in men (otherwise all women would probably belong to the predicate type.) We have, however, reason to assume, as we have already demonstrated above, that the reactions of uneducated subjects, particularly of uneducated women, are based on a (quasi) intentionally produced vividness of the stimulus-image. The association-complex responsible for this is the special view that uneducated people take of the association experiment. As, under the influence of this dominating image, they interpret the stimulus-word mainly from the point of view of meaning, they must apply more attention to stimulus-image, thus necessarily yielding less to distraction, as our figures show. That it is particularly the uneducated women who yield least to distraction agrees with the fact that they are the most strongly under the influence of this particular interpretation of the experiment. That educated women also show a tendency to yield less than men to distraction cannot also be attributed to this particular interpretation of the experiment but must be related to the fact, already mentioned, that among our educated female subjects there are relatively many predicate types, who show practically no distraction phenomenon at all. We therefore give in Table G the average figures of the educated women who are not predicate types.

G. Educated Women excluding Predicate Types



SPECIAL QUALITY	NORMAL		EXTERNAL DISTRACTION

Total Associations	1200		250		250	
Total Subjects	6		5		5	

[463] From the figures of this table it immediately appears that it is not the case that the women's attention is less easily divided than the men's, but that it was the predicate type that strongly affected the average for educated women. Our figures show a definite distraction phenomenon that in no way lags behind that of the men.

[464] Repetitions of the same reactions decrease with distraction; the reasons for this are easy to understand.

[465] The numbers of verbal connections rise under distraction, thus expressing quantitatively the influence on the reaction in terms of external and mechanical factors. It is noteworthy that in uneducated subjects there is under normal conditions not only a greater agreement of grammatical form than in educated subjects but that the distraction experiment increases this even more intensely than in educated subjects, although in uneducated subjects the distraction phenomenon is less distinct. The following differences[64] clearly demonstrate this:

	Women	Men
Uneducated	+3.4	+6.6
Educated	+1.4	+4.7

[466] The figure for the agreement of grammatical form does not only begin at a higher level in uneducated subjects but under distraction rises still higher than the corresponding figure for educated subjects. The reason for this probably lies in the

fact that educated subjects have numerous current phrases at their command even under distraction.

[467] The figures for agreement in number of syllables, aliteration, consonance, etc., need not be commented on.

[468] The almost general decrease of figures for verbal connections in the second part of distraction is connected with the decrease of sound reactions. This change can be attributed to habituation, when the factors of very intense distraction gradually recede.

IV. Average of the Predicate Type under Normal Conditions and under Distraction

[469] Tables H and I give the average figures for all those subjects whom we call "predicate types." We have included in this type all those subjects in whom the internal associations predominate over the group of linguistic-motor forms; the number of predicates is on an average more than twice the number of co-ordinations. Among the subjects used for the calculation of averages there are seven women and two men.[65]

[470] We have placed the average of all other types next to the predicate type for comparison. The difference is striking. The predicate type shows no change worthy of mention under distraction: the predicate type does not show divided attention, while all the other types show themselves accessible to disturbing stimuli, at least to some extent. This fact is extraordinarily strange.

[471] As we have already indicated, we assume that the individuals belonging to the predicate type have basically more vivid images on which attention is already involuntarily fixed in the moment of their emergence (contrary to deliberately produced vividness). We have noticed in our material that among the reactions of the predicate type there are, besides numerous value judgments, also strikingly many predicates designating sensory properties of the object of the stimulus-word, particularly visual ones. Individual subjects reported at once that they sometimes received quite definite plastic images.[66] We based the theory of the predicate type on this observation.

[472] An inner image is vivid if the associations immediately connected with it spring to mind. The nearest associations upon the image of a concrete object are the sensory aspects: the visual, the acoustic, the tactile, and the motor. A vivid image can be said to be in the state of being concentrated upon.[67] The more vivid an image is, the stronger are the inhibitions emerging from it against everything not associated with it; the attention will therefore be all the less prone to be divided. That the distraction phenomenon is virtually absent in the predicate type we regard as proof of the

correctness of our interpretation. The predicate type cannot divide his attention because his fundamentally vivid inner images make so much demand on his attention that inferior associations (which make up the distraction phenomenon) do not occur at all.

H. Averages of Predicate Types

			EXTERNAL DISTRACTION			
SPECIAL QUALITY	NORMAL		60 Met.		100 Met.	
Grouping	12.5		14.8		13.1

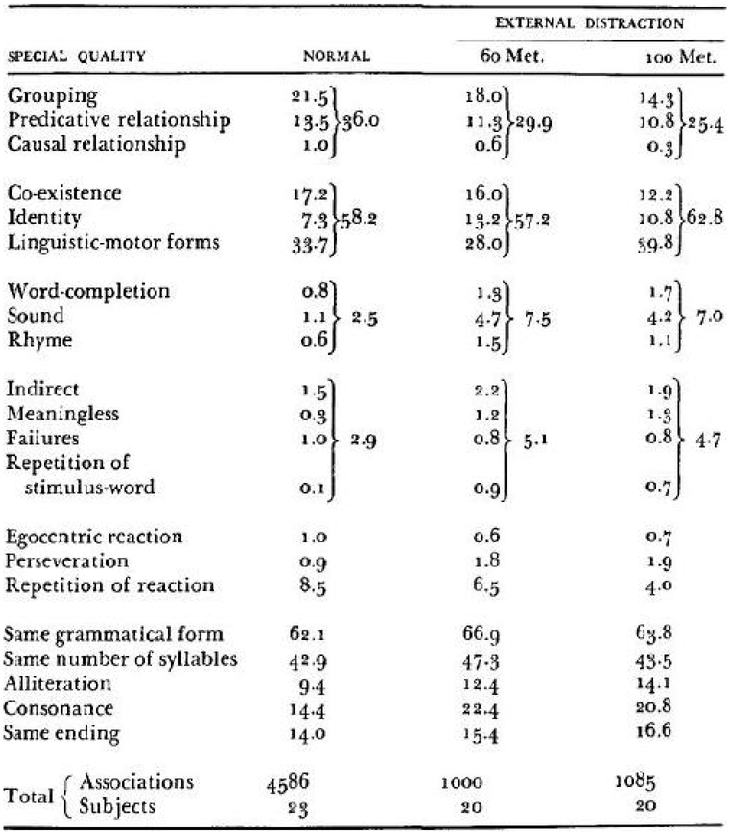
Same ending	6.7		7.7		11.1	
Total Associations	1792		350		350	
Subjects	9		7		7	

[473] By means of our hypothesis all the peculiarities of the predicate type can now be explained.

(1) The large number of predicates. The subjects name a particularly striking characteristic of the inner image and naturally use the predicate for this purpose. The large number of internal associations is mainly to be attributed to the number of predicates. The ratio of internal to external associations reminds us of that in uneducated subjects. The common factor, however, is only the degree of attention applied. The predicates are also retained under distraction, which we regard as clear proof of the involuntary nature of the plasticity of the image.

I. Averages of Non-Predicate Types



SPECIAL QUALITY	NORMAL		EXTERNAL DISTRACTION			
			60 Met.		100 Met.	
Grouping	21.5	36.0	18.0	29.9	14.3	25.4

Total Associations	4586		1000		1085	
Total Subjects	23		20		20	

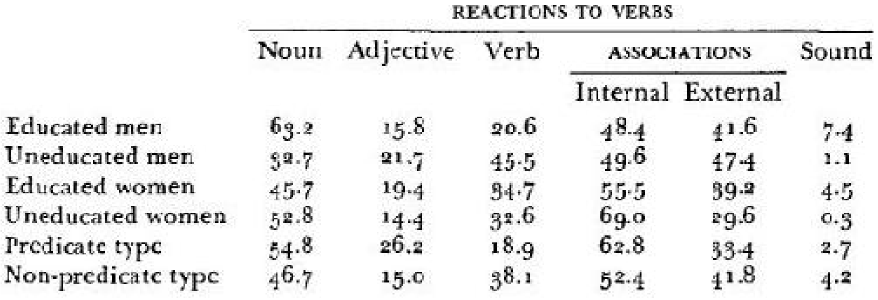
(2) The large number of egocentric reactions. The more vivid the image is, or the greater is the complex of associations present in consciousness, at any given moment, the more it is bound to stimulate and absorb into itself the associations making up the consciousness of the personality, in order by this synthesis to remain conscious. Thus a whole series of personal references must be added to the emerging complex of associations, which are then designated as particularly striking properties of the images and so become reactions. This is how egocentric reactions originate.

(3) The relatively large number of failures. These occur as a rule in reactions to the stimulation of a strong feeling-toned complex, which grips the attention so firmly that no further reaction can take place. It is quite feasible that in the predicate type more feeling-toned complexes are stimulated than in other types as a result of the more vivid images. It follows as an essential consequence of our assumptions that under distraction the failures show a tendency to increase. A certain amount of attention may be left over from what is fixed to the image, but if this is needed for an activity (marking the metronome-beats), then none is left for reacting; no decrease in the number of failures can result from this.

[474] From the figures for the distraction experiment it emerges that the predicate type is not a fortuitous momentary attitude but constitutes an important psychological characteristic, which also obtains under different conditions.[68]

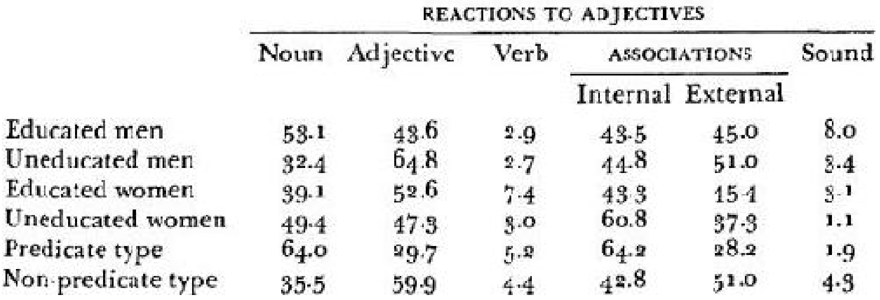
V. The Influence of the Grammatical Form of the Stimulus-word on the Reaction

[475] As can easily be appreciated, the choice of stimulus-word with all its different properties is of some consequence. There is a whole series of stimulus-words that have predictable reactions. Thus, for instance, there is a large number of designations for concrete objects with which coexistent images are regularly associated, quite apart from many stimulus-words that call forth stereotyped word-connections, e.g., *to part / hurts; to part / to avoid; blood / red*. For the quantitative ratios it is of considerable importance whether the stimulus-word is a noun, adjective, or verb. A main factor will then be the frequency of the particular word-form. From a random selection in books one can say that language uses on average twice as many nouns as adjectives or verbs. Thus a noun used as a stimulus-word will, in accordance with the law of frequency, be "answered" more easily than all other word-forms. On the other hand, the lower frequency of verb and adjective will cause rather more difficulty in reaction, quite apart from the fact that, to most subjects, an adjective or a verb in the infinitive, standing outside the context of a sentence, appears more peculiar than a noun, particularly one that is the name of a concrete object, about which something can be said. We have made a comparative examination of this from the material of the experiments under normal conditions and have found the following average figures:



REACTIONS TO VERBS

	Noun	Adjective	Verb	ASSOCIATIONS		Sound
				Internal	External	
Educated men	63.2	15.8	20.6	48.4	41.6	7.4
Uneducated men	32.7	21.7	45.5	49.6	47.4	1.1
Educated women	45.7	19.4	34.7	55.5	39.2	4.5
Uneducated women	52.8	14.4	32.6	69.0	29.6	0.3
Predicate type	54.8	26.2	18.9	62.8	33.4	2.7
Non-predicate type	46.7	15.0	38.1	52.4	41.8	4.2



REACTIONS TO ADJECTIVES

	Noun	Adjective	Verb	ASSOCIATIONS		Sound
				Internal	External	
Educated men	53.1	43.6	2.9	43.5	45.0	8.0
Uneducated men	32.4	64.8	2.7	44.8	51.0	3.4
Educated women	39.1	52.6	7.4	43.3	15.4	3.1
Uneducated women	49.4	47.3	3.0	60.8	37.3	1.1
Predicate type	64.0	29.7	5.2	64.2	28.2	1.9
Non-predicate type	35.5	59.9	4.4	42.8	51.0	4.3

[476] The number of agreements in grammatical form quoted among the individual figures shows that the stimulus-word and reaction do not by any means always agree in grammatical form. The above table shows the average figures, calculated as percentages, for the best-characterized group of our subjects. We decided against giving the individual figures, to avoid a confusing accumulation. Also, the average

figures show most clearly the characteristic variations with which we are essentially concerned.

[477] It is striking that in the verb groups, with one exception, the reactions to verbs were mainly nouns; only the group of uneducated men reacted mainly to verbs with verbs. The educated men reacted mostly with nouns. These (strangely enough) have most in common with the uneducated women, while the educated women are closest to the uneducated men. It is clear from the beginning that the verbal law of frequency has great influence on the preference for this or that mode of reaction. It is therefore quite understandable that educated men, who in any case have a very blunt reaction type, should prefer the readier noun to the rarer verb; it is not so easily understandable that uneducated women should react in an apparently similar way and this needs detailed investigation.

[478] While, according to our observations, educated men usually append nouns to verbs, uneducated men make an effort to do justice to the meaning of the stimulus-word by reacting with a similar verb. A similar effort on the part of the educated women is somewhat less clear. This mode of reaction, the psychology of which we have discussed in detail, is conditioned, as is well known, by the effort to react mainly in accordance with the meaning of the stimulus-word. We have previously seen that uneducated women lead in this respect. Accordingly one would expect that uneducated women would react with an ever higher number of verbs than uneducated men. It must, however, be remembered at this point that the uneducated women's level of education is the lowest, that thus their verbal education and facility is also the lowest; consequently, reacting to verbs will be most difficult for this group, as verbs are even rarer for them than for the other groups.[69] They are therefore dependent on nouns that can most easily be combined with verbs. The uneducated women's effort to produce a meaningful reaction determines the choice of a noun that is not merely joined to the verb but expresses, wherever possible, something significant about the meaning of the verb.

[479] We have therefore carried out a further investigation to test this interpretation and to learn how great is the number of internal associations that are reactions to verbs. With these figures we are in a position to prove our interpretation. We have therefore placed next to the figures giving the preferred word-forms the figures showing the quality of the associations given in reaction to verbs. We give the appropriate figures once more together with those for the experiment under normal conditions for the groups mainly under consideration here.

	EDUCATED MEN		
	Internal Associations	External Associations	Sound Reactio

Normal conditions	36.7	52.7	3.6
Reactions to verbs	48.4	41.6	7.4
Plus difference	11.7		

[480] This table shows that the reaction-type when stimulus-words are verbs is considerably blunter than for the list of stimulus-words mainly composed of nouns. Thus it has been proved numerically that for educated men too there exist far fewer canalized connections between verb and verb than between noun and any of the three other parts of speech. Comparing the appropriate figures for uneducated women with these, we find confirmed our assertion that the nouns preferred by this group possess a higher quality.

	EDUCATED WOMEN		
	Internal Associations	External Associations	Sound Reactio
Normal conditions	46.6	49.4	0.7
Reactions to verbs	69.0	29.0	0.3
Plus difference	22.4		

[481] It becomes apparent from these figures that the vast majority of associations in reaction to verbs are highly significant and appropriate to the meaning of the stimulus-word. The sound reactions in the two groups quoted are also remarkable. Their larger proportion under normal conditions in educated men shows how slight is the influence of the meaning of the stimulus-word. Conversely the decrease of the corresponding figures for uneducated women is characteristic of the increased influence of the meaning of the verbs. From the ratios of these figures it is permissible to conclude that, on account of their lower frequency and consequently the greater difficulty of reacting, the influence of verbs on attention is greater than that of nouns.

[482] The adjectives show, as a glance at the table demonstrates, a reaction analogous to verbs, except that in general they have rather less influence on the reaction-type. It may therefore be assumed that the reaction to adjectives generally encounters little difficulty.

[483] The predicate type reacts to verbs predominantly with nouns, while on the average all non-predicate types react to verbs with twice as many verbs as the predicate type.[70] We examine again the quality of the associations with which the predicate type reacts to verbs:

	PREDICATE TYPE	NON-PREDICATE TYPE

	Int. Assn.	Ext. Assn.	S.R.	Int. Assn.	Ext. Assn.
Normal conditions	45.7	48.6	36.6	58.2	2.5
Reactions to verbs	62.8	33.4	2.7	52.4	41.8
Plus difference	17.4			16.4	

[484] As the plus differences show, the influence of the verbs is roughly the same in both cases; no plus difference of internal associations surpassing that found in the non-predicate type corresponds to the numerous nouns in the predicate type. Thus we have no reason to suppose that in the predicate type the verb has a greater influence on the attention, that is, that it presents greater difficulties in reaction. The predicate type shows no difference of attention in relation to the verb but only the difference that educated subjects in general display, namely, that they prefer the noun on account of its greater familiarity. This is because in our predicate types the majority are educated subjects.

[485] The reaction of predicate types to adjectives is in contrast to our earlier findings. As the figures in the tables show, in the four groups first dealt with more adjectives are given as reactions to adjectives than verbs to verbs. In the predicate type, which is mainly distinguished by attributes in adjective form, the difference is only 10.8 per cent. On the other hand, nouns are given greater preference (as opposed to non-predicate types)—namely, 28.5 per cent more. This preference for nouns is caused by the predicate type’s effort to react mainly in the form of attributes and not only, as our figures show, by reacting with a predicate but also, conversely, by discovering a noun for an adjectival stimulus-word.[71] Let us now examine the proportions with reference to the quality of adjectival reactions.

	PREDICATE TYPE			NON-PREDICATE TYPE	
	Int. Assn.	Ext. Assn.	S.R.	Int. Assn.	Ext. Assn.
Normal conditions	45.7	48.6	1.5	36.0	58.2
Reactions to adjectives	64.2	28.2	3.9	42.8	51.0
Plus difference	18.5			6.8	

[486] As these figures show, the large number of nouns in the predicate type is connected with a rise of internal associations. Thus we do not in this case have a mere juxtaposition of familiar nouns but constructions that, owing to the particular mental attitude of the subject, are matched to the stimulus-word. This although, in view of the figures for the other groups, the juxtaposition of a similar adjective seems easier for them. The latter is clearly demonstrated by the small plus difference of internal associations in the adjectival reactions of the non-predicate type.

[487] It also becomes clear from the figures for adjectival reactions that the predicate attitude is by no means fortuitous but corresponds to a quite definite psychological

disposition, which is maintained even when other modes of reaction would be much easier than the predicate form.

SUMMARY

[488] The associations show normal variation, principally under the influence of:

(1) Attention

(2) Education

(3) The individual characteristics of the subject

[489] (a) Decrease of attention owing to any internal or external factors causes a blunting of the reaction type, i.e., the internal or fully valent associations recede in favour of external associations or sound associations.

(b) Distraction of attention according to our experimental design caused, apart from the above-mentioned changes, an increase of indirect associations which must therefore be interpreted as distraction phenomena and can be derived as internal links from the competition of two weakly stressed (less valent) associations.

(c) Educated subjects have a blunter reaction-type on the average than uneducated. The difference can essentially be explained by a difference in the interpretation of the stimulus-word.

(d) No essential differences emerged in the degree of division of attention by distraction between educated and uneducated subjects.

(e) The most considerable variations in associations are conditioned by individual differences.

[490] (1) As regards the effect of sex on the mode of reaction under normal conditions no clear differences emerge from the average figures. Only in the distraction experiment does the peculiarity of female subjects show, in that they possess less ability to divide attention than male subjects.

(2) The individual variations can be classified into the following types:

I. *Objective type*. The stimulus-word is taken objectively, that is:

(α) mainly according to its objective meaning; the reaction is matched to the sense of the stimulus-word as much as possible and linked by meaning to the stimulus-word.

(*β*) mainly as verbal stimulus; the reaction is in part matched purely verbally, in part it merely marks the juxtaposing of a canalized association, in which the meaning relationship rather recedes into the background.

II. *Egocentric attitude*. The stimulus-word is taken subjectively (egocentrically).

- (α) *Constellation type*. The personal elements used in the reaction belong to one or more emotionally charged complexes, there being two possibilities:
    - (αα) The complex-constellations are spoken without concealment.
    - (*ββ*) The complex-constellations appear in veiled form as a result of a not always conscious repression.[72]
- (*β) Predicate type*. This type has presumably the psychological peculiarity of particularly vivid (plastic) inner images, by which its particular mode of reaction may be explained. This type also shows at best an abnormally low ability to divide attention, which is expressed in the distraction experiment by an, on the average, almost complete lack of blunting phenomenon.

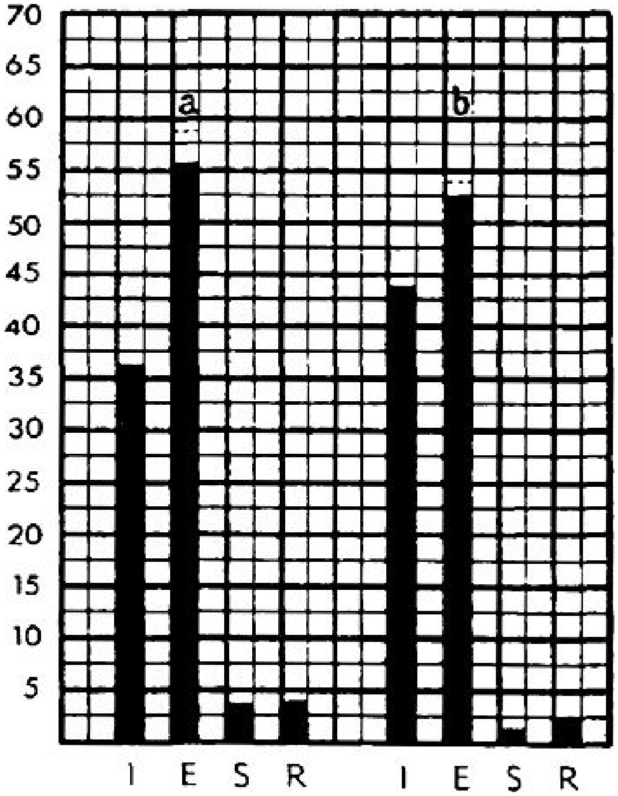
[491] As a general result important for pathology, it emerges that the blunting of reaction-type in fatigue, alcoholic intoxication, and mania may be attributed primarily to a disturbance of attention. The observations on the affective side of associations (effects of feeling-toned complexes) might be of importance for the experimental investigation of pathological feeling changes and their consequences.

[492] Finally we may be permitted to express our sincerest thanks to our esteemed director, Professor Bleuler, for valuable encouragement. We are also particularly grateful to Mrs. Jung for active help in the repeated revision of the extensive material.

EXPLANATION OF GRAPHS

[493] In the accompanying graphs the arithmetical means of internal associations, external associations, sound reactions, and reactions in the residual group of different groups are presented. The averages shown are:

I: internal associations
E: external associations
S: sound reactions
R: reactions in the residual group

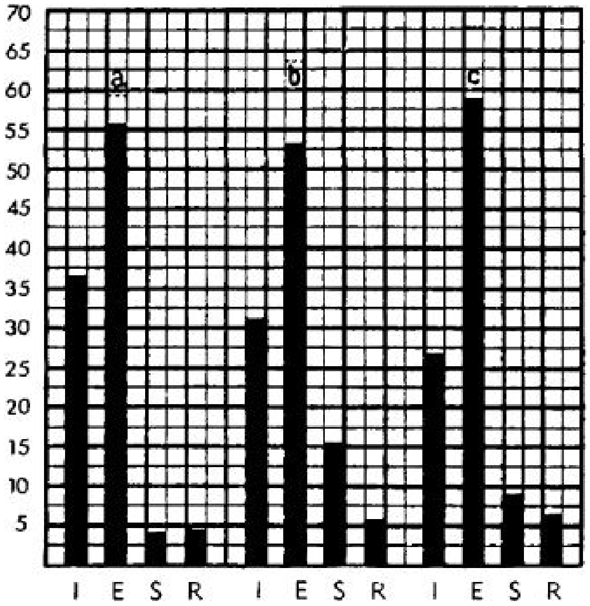


Graph I. Averages from Experiments under Normal Conditions

(a) Educated Subjects: 23 subjects, 3,800 associations

(b) Uneducated Subjects: 18 subjects, 3,000 associations

[494] *Graph I.* The educated subjects have fewer internal, more external and more sound associations under normal conditions than the uneducated subjects.



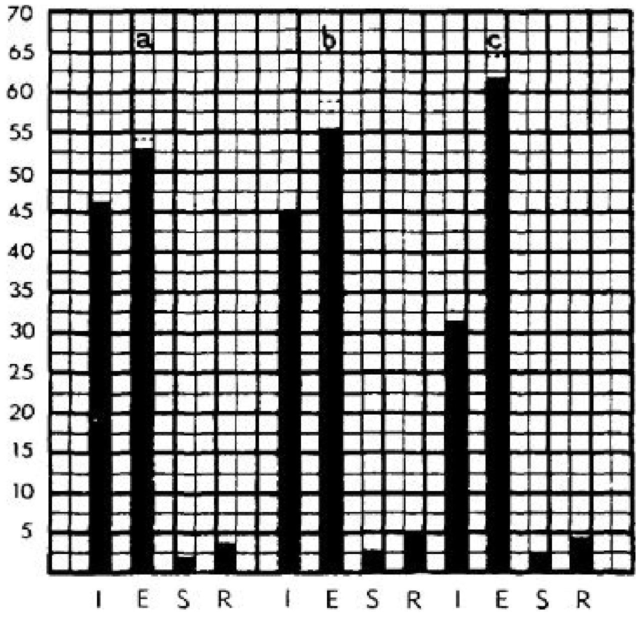
Graph II. Averages from Experiments with Educated Subjects under External Distraction

(a) Normal conditions (Graph I, a): 23 subjects, 3,800 associations

(b) Distraction experiment with 60 metronome-beats per minute: 13 subjects, 650 associations

(c) Distraction experiment with 100 metronome-beats per minute: 13 subjects, 835 associations

[495] *Graph II*. A definite, regular decrease of internal associations from *a* to *c* is found, i.e., according to the intensity of the method of distraction. Secondly, an increase of sound reactions in both distraction experiments emerges from the graph. The result of distraction consists in general of an increase of external associations plus an increase of sound reactions. This sum (E + S) is indicated in places by adding to column E a dotted column equal to the height of S. This column (E + S) increases regularly from *a* to *c*. The decrease of I and the increase of (E + S) under distraction demonstrates clearly the effect of distraction. *Sb* and *Sc* are both bigger than *Sa*. The reactions in the residual group increase from *a* to c.



Graph III. Averages from Experiments with Uneducated Subjects under External Distraction

(a) Normal conditions (Graph I, b): 15 subjects, 3,000 associations

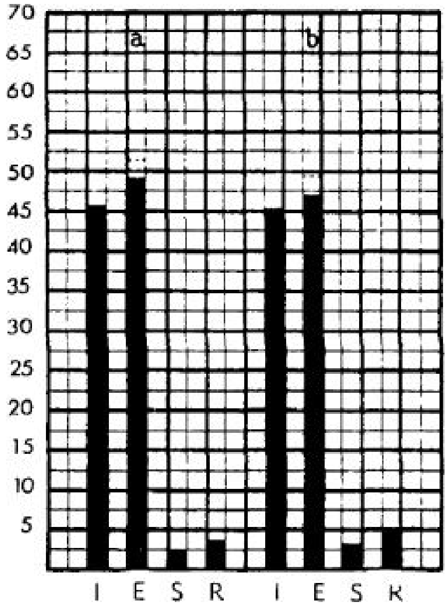
(b) Distraction experiment, 60 metronome-beats: 15 subjects, 750 associations

(c) Distraction experiment, 100 metronome-beats: 15 subjects, 750 associations

[496] *Graph III*. The picture, apart from the different starting point, is similar to the distraction experiment with educated subjects:

Gradual decrease of internal associations from *a* to *c*;

Gradual increase of external associations plus sound reactions from *a* to *c*. R increases under distraction, S only a little, the sound reactions generally play a much smaller part than in educated subjects.

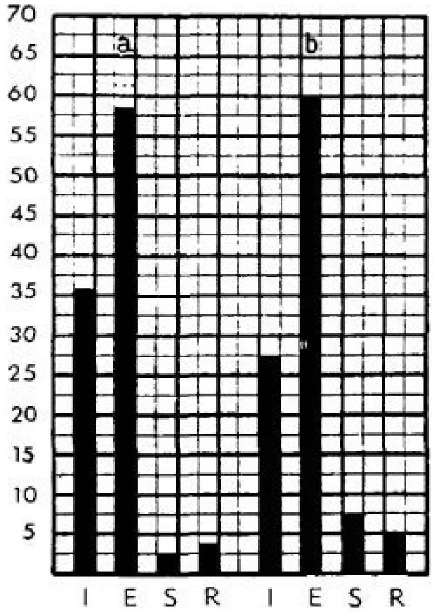


Graph IV. Averages from Experiments with Subjects of the Predicate Type (Educated and Uneducated)

(a) Normal conditions: 9 subjects, 1,792 associations

(b) Distraction experiments (60 and 100 metronome-beats taken together): 7 subjects, 700 associations

[497] *Graph IV.* While in educated subjects the ratio of I : E is 2 : 3, and in uneducated subjects I : E is 5 : 6, here it is 1 : 1.1. S is smaller than in educated subjects but greater than in uneducated under normal conditions. In group R the ratio is inverted. Strikingly enough, in contrast to the preceding pictures, this ratio hardly changes under distraction. There is only a minimal decrease of I and a very small increase of (E + S). R has increased a little.



Graph V. Averages of all Experiments in the Remaining Subjects (Non-predicate Types)

(a) Normal conditions

(b) Distraction experiment

[498] *Graph V.* The picture is a striking contrast to the picture in graph IV. Under normal conditions the ratio I : (E + S) equals 10 : 17, approximately 2 : 3; in the distraction experiment 10 : 24, approximately 2 : 5. S increases considerably, R less.

AN ANALYSIS OF THE ASSOCIATIONS OF AN EPILEPTIC[1]

[499] Epilepsy is one of the few mental diseases of which the symptomatology is particularly well known and delimited by innumerable clinical and systematic inquiries. Psychiatry has shown that in the epileptic, besides the symptoms of the fit, there is usually a mental degeneration that can be claimed to be specific and therefore of diagnostic value. Here are the principal traits of those epileptics who show degeneration according to the recognized textbooks of psychiatry:

1 *Intellect*. Mental debility, slowness of mental reactions, fussiness, restriction and impoverishment of ideas combined with poor and stereotyped vocabulary, frequently abnormal preponderance of fantasy.

2. *Emotional disposition*: Irritability, moodiness, strong egocentricity, exaggeration of all feelings, particularly religious ones.

[500] These attributes comprise what is known as the epileptic character, which, once established, has to be considered a permanent formation. Transitory accentuations of one or the other trait are quite likely, radiating like ripples from occasional fits. It is occasionally possible to make the diagnosis with sufficient certainty by recognizing the epileptic character, even if fits are not known to have occurred. Such cases, however, are on the whole rare. Very frequently the epileptic character is not very obvious, particularly if the fits are infrequent. It would therefore, for practical purposes, be most valuable to find a method of concise formulation of the epileptic degeneration.

[501] Repeated attempts to investigate the permanent epileptic changes by means of experimental methods have recently been made: thus Colucci[2] and Breukink[3] tested by means of the ergograph; Sommer[4] and his pupil Fuhrmann[5] in particular turned their attention towards associations in epileptics. We consider the latter research as particularly suited for a precise formulation of epileptic degeneration.

[502] Fuhrmann reports on an investigation into the associations of two epileptics. The first concerns a patient who was taken ill in his tenth year. The author found that predicates in particular occurred repeatedly and that egocentricity played a prominent part. Not all reactions could be regarded as “associations”; there were also verbal reactions, the content and form of which had no inherent connection with the stimulus-word. Fuhrmann calls these reactions “unconscious.” They appear mainly at the beginning of the test sequence

(according to the table given by Fuhrmann). Test sequence I starts with the following reactions:

1. bright	faith
2. dark	health
3. white	arm
4. black	blue
5. red	parents
6. yellow	father
7. green	chair
8. blue	arm

[503] Fuhrmann does not attempt any interpretation. Kraepelin[6] mentioned this observation in the latest edition of his textbook, where he states:

> [It seemed] as if these ideas, only released but not produced by the experiment, emerged from permanent general trains of thought. Their contents were mainly related to the illness or else to the patient's personal circumstances. We may well assume that the frequency of such associations, determined by inner conditions, not by external stimulation, is particularly facilitated by the mental slowness of epileptics, which prevents them from associating quickly and easily with the stimulus-word, as normal people do.

[504] In 1903 I demonstrated the frequent occurrence of such meaningless connections in an imbecile in a state of emotional stupidity in my paper "On Simulated Insanity." Wehrlin[7] recently expressly referred to these facts, supported by evidence, in his research on associations of imbeciles and idiots. According to our experience these meaningless reactions always occur when the patient is in a state of emotional stupidity, which can, of course, occur in quite a number of mental abnormalities. These "unconscious" reactions are therefore not at all specific for epilepsy.

[505] Let us return to Fuhrmann's paper. In the first case a repetition of the experiment with the same stimulus-words was carried out after about a month.

[506] The second case concerns a patient who had been ill since he was sixteen. Here the experiment was repeated four times within eight months, and a considerable restriction of the extent of the associations, a striking monotony in the reactions, could be observed. Basing his opinion on the associations of two female idiots, Fuhrmann considers that there is a "marked" difference between epilepsy and idiocy, in that general concepts have no meaning for idiots. Wehrlin's investigation shows that the idiot is aware of general concepts but

these are extremely primitive. Thus the difference may be more subtle than Fuhrmann appears to assume.

[507] Riklin, in his notable paper on "Relieving Epileptic Amnesias by Hypnosis,"[8] reports on several association experiments with epileptics. This author deals more with the qualitative aspect of the reactions and arrives at a variety of important findings.

[508] He finds a clinging to the content of a reaction and to the same grammatical form, strong egocentricity, personal constellations, a frequent emotional charge in the content of the reaction, and a paucity of ideas.

[509] These peculiarities are to a great extent nothing but reflections of the epileptic character. Riklin states that it is possible to read the signs of epileptic degeneration from a sequence of associations. In scrutinizing Riklin's observations, however, it has to be pointed out that: (1) Perseveration of the grammatical form need by no means always be an epileptic symptom. Wehrlin's paper shows very marked perseveration of grammatical form in imbeciles and idiots. (2) Perseveration of the content occurs also in normal subjects, as I have shown, together with Riklin, in the first contribution of the Diagnostic Association Studies.[9] Egocentricity and personal constellation too happen in the normal and in the feeble-minded, as well as feeling-toned reaction-contents. The paucity of ideas is, of course, not characteristic for epilepsy, but for mental deficiency generally, and in a certain sense also for emotional stupidity, where it assumes the special form of "associative vacuum."

[510] In epilepsy therefore it is a question of the quantity of these symptoms in any given case. It will also have to be considered whether they may perhaps have a more specific quality. I have made it my task to clarify these issues and to attempt to separate what is specific for epileptic associations from the various types of the normal and from congenital mental deficiency. Such an investigation has, of course, to be based on extensive material. The Swiss Asylum for Epileptics in Zurich, with its large numbers of patients, offered a favourable opportunity.

[511] The material comes mainly from this institution, where it was collected by the Medical Superintendent, Dr. Ulrich; some of it came from the Burghölzli Asylum for the Insane. The total number of experimental subjects was 158, the total number of associations 18,277. This extensive material allowed us to form some ideas about associations in epileptics; for this reason Dr. Ulrich and I began a methodical inquiry into this subject which contains so much of interest.

In order to comprehend the essence of the abnormalities of epileptic association as fully as possible, I classified the material as follows:

[512] First, I excluded those cases who were not congenitally mentally defective and those who only contracted epilepsy after leaving school, i.e., after puberty.

[513] By doing this I discarded the cases, so frequent among epileptics, that are complicated by congenital mental deficiency. According to Wehrlin's paper, it seems that imbeciles have a rather characteristic type of association which is mainly marked by the tendency to "define" the stimulus-word. The first records of epileptics showed us association types which from the very beginning revealed the greatest similarity to the imbecile type. In cases of epilepsy complicated by imbecility or by mental degeneration in early youth, the similarity was even greater. In order to find the specific epileptic, it was necessary to eliminate the cases we have mentioned.

[514] For practical reasons the field of inquiry was further divided; in this paper I am analyzing the reactions of a typical case as fully as possible, and in a forthcoming publication Dr. Ulrich is going to discuss the variants of the epileptic types of association.

[515] Before dealing with the observations themselves, I must make a few remarks about the technique of obtaining the associations.

[516] The preparation of the subjects for the experiment is by no means unimportant. One has to consider that as a rule people have no idea what the experiment demands of them; therefore they easily get bewildered. If they become markedly so, this has a distinct influence on the result, as I have repeatedly seen. We therefore introduce the experiment in each case with an instruction: the subject is told that some random word is going to be called out, to which he or she has to answer as quickly as possible with the word or idea that comes to mind without reflection. The instruction is illustrated by a practical example in which the experimenter gives a reasonably complete list of the possible associations. In this way the subject is enabled to select freely from this list the reaction that appeals to him most. The unbiased subject will, of course, choose the type of reaction that is characteristic of him. We take special care that the subject does not make a special effort to respond, if possible, with one word only. If this is, nevertheless, the case, then the characteristic form of the response becomes completely obscured and the reaction-time is considerably shortened. In women it is often necessary to subdue a nascent

emotion by talking casually about the experiment. I usually do this by presenting the experiment as a kind of game.

[517] For these experiments a new list of stimulus-words was used. I chose two hundred words; 75 of them denote concrete ideas, 25 denote abstract ideas, 50 of them are adjectives, and 50 are verbs. The sequence is as follows: noun-adjective, noun-verb. They are as mixed as possible so that related stimulus-words do not occur in immediate sequence. No attention was paid to the number of syllables. The stimulus-words were taken from widely varied fields of everyday life, unusual words being avoided as much as possible. Intentionally a number of emotionally charged ideas were interspersed, such as love, to kiss, bliss, friendly, etc., because a particular significance is attached to these words. The reaction-times were checked by a ⅕-second stop-watch.

[518] I have chosen the following case from our material:

M. Joseph. Toolmaker, born 1863, widowed, no children. 19 convictions. No family history of illness admitted. Good at school, completed a three-year apprenticeship with a locksmith. Good testimonials. No major illness during early years, particularly no sign of epilepsy. Married in 1888. In 1893 his wife contracted a psychosis and died soon after in a lunatic asylum. After his wife was taken ill, the formerly stable and industrious patient began wandering about all over Europe. He left every place of employment after a short time, took to drink, travelled aimlessly about, even in forests. During this period there were frequent collisions with the police, mainly for theft. The patient claims amnesia for most of them. In 1893–94 he was three times in lunatic asylums for violent *mania transitoria*. In 1896 he fractured his skull. In 1896–98 he was again in various lunatic asylums for delirium. In 1898 one-sided twitching, occurring in fits, was noticed. At that time a relatively lucid delirium, with plastic and very stable visions, was observed, and the patient described it with much emotion. The end of 1904 was spent by the patient aimlessly in the mountains eating only poor food. Following a drinking bout, he stole a bicycle. After the theft he wandered aimlessly about and then came into the hands of the police. He was brought in here for observation, which revealed:

Mental deficiency in an epileptic character. Frequent short lapses of consciousness with aura: “Sees black dots, five to six in a row, which are always moving up and down; head feels as if in a clamp or pressed together by screws; chest feels as if a drop were trickling down inside it; there is buzzing in the ears, then fear overcomes him as if he had done something wrong, or he has pains in the back that rise to the head; he has the feeling that he wants to tear everything up, or it is as if a railway engine suddenly rushed towards him." After this aura he gets giddy, everything is spinning around him and he loses consciousness. The lapses of consciousness were also observed during conversation and particularly while playing cards. Intolerance of alcohol to a high degree.

[519] The associations in this case seemed to me in various respects rather typical for epilepsy, although not all the characteristic symptoms appear in them. This is because each case has its peculiarities, so that here too rather an important role is played by the individual differences between the various reaction-types.

		Secs.
1. coal	hard coal	7.2
2. moderate	eating little	12.0
3. song	to sing, to sing a song	6.2
4. to assume	I assume, what do I assume? several things	23.2
5. pain	because I am ill	4.2
6. rotten	if an apple is rotten, a plant, everything can get rotten	5.8
7. moon	that is the moon in the sky, here we have the moon	3.4
8. to laugh	man laughs	4.2
9. coffee	one drinks it, drinks it every day	4.0
10. wide	this is the width of a distance (accompanied by an explanatory gesture)	6.2
11. air	this is the air, nature's air, healthy or unhealthy, fresh air is fresh air	2.2
12. to carry (to wear)[10]	I carry (or wear) something, a burden or fine clothes	5.0

[520] These first twelve reactions already allow some conclusions. Above all it is striking that the subject reacts not with *one* word but usually with whole sentences. This fact has a certain significance. In my experience, which is supported by the material of more than thirty thousand normal associations, healthy people as a rule tend to react with one word (N.B. after being instructed as explained above). There are exceptions when even educated people may prefer the form of a sentence; Riklin and I quoted such an example in our paper on the associations of healthy people. That subject belongs to the "complex-constellation type," i.e., to that reaction-type whose associations are at the time

of the experiment under the influence of an affect-charged complex of ideas.[11] In such cases one recognizes at once the peculiar constellations from the contents of the associations. I refer to this quotation. Among healthy people there is also a type who likes to react with two or more words, though not actually in sentence-form:

[521] *The Predicate Type.*[12] People belonging to this type tend mainly to judge and evaluate the object described by the stimulus-word. This is, of course, done in predicate form; thus the tendency is quite obvious and the use of several words sufficiently explained. Certainly neither of these types can be confused with the reactions that now concern us.

[522] In the pathological field, however, the sentence form is so frequent and occurs so widely that one can hardly recognize in it anything pathognomonic.

[523] An observation (which I cannot, it is true, support at present by figures) has to be mentioned: uneducated mental patients appear to tend more to form sentences than educated ones. Should this observation become confirmed, it would not be difficult to combine it with the fact that uneducated people are more concerned with the meaning of the stimulus-word than are educated ones, as has already repeatedly been stressed in previous papers. Uneducated people at a very low level, who tend to “answer” with something that is as “fitting” as possible and to explain the stimulus-word as well as possible, need more words for it than educated ones, who merely juxtapose words. This tendency to explain becomes most obvious in idiots and imbeciles, who very frequently form whole sentences.[13] Our subject shows a preference for sentences which, in the absence of sufficient data, is difficult to understand; it may therefore be inferred that we are faced with some abnormality.

[524] Before dealing with the contents of the reactions we must pay some attention to the reaction-times. These are abnormally long. (The average reaction-time of uneducated subjects is 2.0 sees.) This does not permit us to draw any conclusions at present, because there is no syndrome in which the reaction-time could not be prolonged. As is well known, Aschaffenburg found somewhat extended reaction-times also in manic patients. It may, in any case, not be advisable to investigate the reaction-times found in the association experiment, isolated from the analysis of the association contents, because they depend to a high degree on the momentary contents of consciousness.

[525] Let us now consider the quality of the associations. We notice at once that the subject focuses on the meaning of the stimulus-word; there is an outspoken

tendency to clarify and characterize the object denoted by the stimulus-word. Wehrlin described this tendency as particularly characteristic for congenital mental deficiency. Perhaps, however, the strong tendency to explain occurs in every variety of mental defect, and it may be assumed that the feeble-minded converge in some respects towards the congenital mental defective, even if the causes of the two conditions are entirely different. The tendency to explain is so obvious in our case that here too we can without difficulty demonstrate the kind of explanation found by Wehrlin among imbeciles. Reactions such as these can be regarded as "tautological clarifications":

to assume	I assume
to carry	I carry something
air	this is the air

[526] These can be taken as explanation by "examples":

moderate	eating little
rotten	if an apple is rotten
wide	this is the width of a distance (with explanatory gesture)

[527] These indicate the main quality or activity:

to laugh	man laughs
coffee	one drinks it

[528] From this we can see no more than a very marked conformity with the explanatory tendency of imbeciles. Moreover, one can even say that the subject is taking pains not to be misunderstood in this respect. Thus he is adding something that confirms and elaborates the explanation in places where there is some doubt whether it is a superficial familiar word-connection, such as in *song / to sing, coffee / one drinks it*.

song	to sing, to *sing a song*
coffee	one drinks it, *drinks it every day*

(Similarly in 4, 11, 12.) These examples show that the subject needs to accentuate his tendency to explain.

[529] Out of the twelve reactions cited, which show a tendency to explain, we find three containing the word "I." Such reactions belong to the egocentric type. There are egocentric reactions in the normal as well, particularly in subjects with an "egocentric attitude."[14] This attitude can express itself in three different ways:

1. The subject reacts with a number of personal reminiscences.

2. The subject is under the influence of an emotionally charged complex of ideas. He relates almost every stimulus-word to himself (i.e., to the complex) and responds to it as if it were a question concerning the complex (a prototype of paranoia, therefore!).

3. The subject belongs to the predicate type and evaluates the content of the stimulus-word from the personal angle.

[530] In these three types the subject puts himself occasionally into the foreground. Apart from this, egocentric reactions occur as a rule somewhat more frequently in the educated than in the uneducated, but mainly when the subjects are at their ease. For uneducated men we found an average of 1.7 per cent egocentric reactions, for uneducated women only 0.5 per cent. All the more remarkable is the strong predominance of egocentricity here. The cause of it could in the first place be ascribed to mental deficiency. Imbeciles use personal reminiscences relatively often because, owing to their narrow horizon, they have no others available. Wehrlin has given good examples of this. Figures found in our material obtained from imbeciles have shown a fluctuation of the numbers for egocentric reactions between 0 and 2.7 per cent. Among fifteen imbeciles there are no more than nine who show egocentric reactions. It must, however, be mentioned that in Wehrlin's material[15] there is an imbecile who is distinguished by the fact of having produced no less than 26.5 per cent egccentric reactions. This is quite an unusual result, for special reasons. This imbecile is also different from the other subjects in that he has not an actual tendency to explain, but with each stimulus-word he forms a "schoolroom-type" sentence which often begins with "I"; e.g.,

fall[16]	I fall down
to loathe	I loathe rotten fish
head	I have a head
to run	I run swiftly
advice	I ask father's advice
reward	I deserved the reward

[531] The examples show that, as Wehrlin has already mentioned, this imbecile is mainly trying to formulate correct "schoolroom" sentences, saying "I" in places in which other imbeciles say "one" or "the man." The description "egocentric" can therefore be applied to this case only with some qualification. As already mentioned, this case is an exception and does not alter the fact that as a rule imbeciles avoid the ego-reference. Egocentric reactions in imbeciles are not

much in evidence; on the contrary, the subjects prefer the expressions “one,” “someone,” etc., in order to avoid the “I”-form. Hysteria, too, which has numerous ego-references, prefers the less suspect “one.”

[532] Our case, with his outspoken tendency to explain, also shows a prominence of egocentric reactions, such as we do not find in imbeciles with the same tendency to explain. One can object that R.12, *to carry / I carry something*, is a “schoolroom” sentence. But one cannot make this objection to 5, *pain / because I am ill*.

[533] It is strange enough to see the strong egocentric aspect in imbecility; it is even stranger to observe the peculiar way in which the subject words his explanation.

[534] I have already pointed out that in a way the subject accentuates his tendency to explain by repeating his reactions in a confirmatory way, finally adding an attribute. But the subject goes even further; he is not satisfied with a simple reaction, but it evidently gives him special satisfaction to make his explanation more complete.

[535] In R.4, *to assume / I assume, what do I assume? Several things*, one can virtually see how he is trying to bring something more descriptive into it. He gets into an entirely abnormal excitement with R.11, *air / this is the air, nature’s air, healthy or unhealthy, fresh air is fresh air*.

[536] The urge to completeness leads to pleonasm in R.10, *wide / this is the width of a distance* (with explanatory gesture). (See also 6, 7, 12.)

[537] In the reactions 11, *fresh air*, and 12, *fine clothes*, the attributes seem to give quite a special emphasis. The effort with which the subject reacts suggests some inadequacy because this display of words goes far beyond what would be necessary to cover the stimulus-word. This fact at once gives the impression of an unnecessary and exaggerated tendency to elaborate. Precisely this trait is absent in the imbecile; he is satisfied with a not too long reaction that appears to him reasonably suitable, but which frequently does not get beyond the most primitive indications and quite undeveloped concepts. Our subject, however, has a strong inclination to accumulate and to elaborate the reactions, occasionally far beyond what is necessary.

[538] The twelve reactions quoted give us reason to suspect feeblemindedness which is specifically tinged by a strong tendency towards egocentricity and elaboration.

[539] Let us now see our patient’s further reactions:

13. plate	dinnerplate—dinnerplate—for dining	

The reaction is repeated with emphasis as if in confirmation. As it is not enough, it is further defined; an unnecessary reiteration. Quite similarly constructed, but even more specific, is

14. tired	I am tired—yes, tired—the body is tired	3.0
15. intention	I have the intention—to invent a machine—to draw—to provide—to live properly	13.0

This reaction too is overdone. It contains two explanations by means of definite examples, one of which is a personal constellation (the subject is a toolmaker) and three times qualified.

16. to fly	the bird flies	4.8
17. eye	the eye sees	2.8
18. strong	am strong, that is strong	4.6

Again a clumsy ego-reference followed by a confirmatory but unnecessary sentence.

19. fruit	this is a fruit, a *tree-fruit*	7.0

The tendency to confirm and complete leads here to the formation of a new word *tree-fruit* (see also below on this reaction).

20. to create	to work hard means to create	3.6

To work has an emotionally charged attribute.

21. sail	a sail is a sailing boat on the water	6.8

Note the repeated return of the stimulus-word in the reaction. Up to now there were no more than three associations in all in which the stimulus-word did not recur in some form.

22. modest	yes, man is modest when he has learned something	9.0

Yes is an expression standing for a feeling that is about to take the shape of ideas and words (see R.14). Wherever strong feelings, either easily aroused or very intense, are involved (as in hysteria and certain organic brain-lesions), *yes* and *no* are frequent. The content of this association points to a train of thought hardly to be found in someone born mentally defective.

23. floor	floor of the room	3.8
24. to whistle	I whistle	3.2
25. purpose	for what purpose? For what purpose are you doing this?	5.6

The reaction is particularly striking because of the repetition of the stimulus-word. Here again we can see that the subject understands the stimulus-word as a question.[17]

26. hot	it's too warm, too hot	2.0

Up to now, hardly one of the reactions shows as well as this one the subject's tendency to confirm and complete the reaction with emphasis. It is as if the subject is each time trying to clarify the meaning of his reaction with special vigour. This emphatic underlining shows up well in the accentuation *too warm, too hot*.

27. resin	fir resin, the resin grows on the fir-tree, on the pine-tree	3.8
28. to arouse	I arouse—I arouse my friend, he is asleep	8.4

Both reactions are again characterized by great completeness, especially the latter, where the subject even completes the picture by *he is asleep*.

29. apple	there are various apples	6.6

This reaction can be found extremely frequently in exactly the same form in imbeciles.

30. wicked	one says, who is wicked? so-and-so is wicked, that is a wicked person	6.0
31 case	a brief-case	3.0
32 to drink	I drink lemonade	3.0
33. bed	sleeping—I have the bed for	3.0
34. worthy	that person is worthy to whom him honour is due (*sic*)	94

This reaction has linguistically miscarried. Epileptic mental deficiency seems to have in common with congenital mental deficiency that the patient is clumsy and arbitrary in the handling of the language. In imbeciles we find many faulty formulations of sentences and also clumsy neologisms. However, in the association experiment one must not simply ascribe linguistic clumsiness to mental deficiency, since there may also be momentary emotional disturbances that interfere with the linguistic expression. We shall come back to this later.

35. danger	I am in danger, in danger of life	4.2
36. to visit	I visit a patient	4.8

The latter reaction may again be an ego-reference.

37. locksmith	I am a locksmith, an artisan	2.8
38. high	the steeple is usually high	4.8
39. hatchet	the hatchet is an axe	3.4
40. to mix	don’t mix yourself up in other people’s affairs	6.2 210

This reaction very much resembles a common phrase. It is the first in this case. As is well known, just such reactions are very common in normal subjects.

41. path	that is a footpath, a field-path	3.2
42. round	it is a sphere, otherwise it is not a sphere, if it is not round	3.8

A reaction very typical of the pedantic fussiness of the subject.[18]

43. blood	every man has, every animal only good or bad, that is the difference	3.4

In this long-winded reaction we again find similar evaluations to those in R.11. There it was *healthy or unhealthy air*, here it is *good or bad blood*. The constellation common to both is apparently the question of health, which is important for the patient. R.5 and R.36 also refer to this complex. The strong predominance of the illness-complex in the associations of the epileptic has also been stressed by Fuhrmann.

44. to let	I let lodgings	6.0
45. cautious	Man, be cautious	4.8
46. merry	I am merry, I am gay	3.6
47. market	the annual fair, that is a market, the fair at Basel only recently took place	7.0
48. to forget	I have forgotten something	5.0

49. drum	the kettle-drum is a drum	3, 2
50. free	I am free—I am free, I am a free citizen, it would be nice if only it were true	4.0

In this reaction, apart from the repeated emphasis on *free*, the egocentric relation, clothed in the evaluation *nice*, is noticeable.

51. carriage	a carriage, a team of horses	4.4
52. to eat	I am eating, I am eating a stew	2.4
53. insolence	if a person—there are people who are insolent, insolent in their speech, insolent behaviour	6.8
54. fast	the engine runs fast (probably a constellation arising from his daily work)	3.8
55. fireplace	is a chimney, a factory chimney	2.4
56. to enjoy	I enjoy an evening entertainment, I enjoy pleasure	4.0
57. parson	is a clergyman, a pastor that ought to be a righteous man	2.2

To the reaction, which would be quite sufficient in itself, a feeling-toned evaluation is attached. It resembles R.15: *intention to live properly*. Are these perhaps indications of a tendency in the epileptic to moralize?

58. easy	what is not easy is difficult	5.0
59. neck	is the neck (points at his neck) every man has a neck	2.8
60. to wish	I wish you luck in the New Year	3.0
61. stone	a marble stone, there are various stones, stone is a product of nature[19]	4.6

Imbeciles too are inclined to use abstract nouns of foreign origin (substance, material, article, etc.), which, however, they frequently use in a truly grotesque way.

62. distinguished	the educated man is distinguished	6.2
63. hose	the rubber hose is a hose	4.0
64. to love	I love my neighbour as myself	5.0

This reaction seems to me characteristic for the epileptic: Biblical form, strong emotional charge, and egocentricity. For comparison I assembled the reactions to *to love* of ten imbeciles chosen at random:

1. friendly
2. to be angry
3. fiancé
4. if one loves someone
5. pleasant
6. I love father
7. if one loves one another
8. if two are fond of each other
9. if one likes someone
10. if one loves someone

With one exception (6), the imbeciles react very impersonally and in a considerably less colourful way than the epileptic.

65. tile	there are grooved tiles in Basel	
66. mild	is mild weather, is mild, is warm	2.8

[540] It is hardly necessary to pile up any more examples. The further associations of this case contain nothing fundamentally new.

[541] Some more general clarifications may be useful. It must first be mentioned that the subject made gestures with most reactions (which were indicated each time by a tick on the association form). The gesture expressed, wherever possible, confirmation and completion. Secondly, the stimulus-words were repeated in 30 per cent of the reactions. As I shall demonstrate in a later paper, “The Reaction-time Ratio in the Association Experiment,” the repetition of the stimulus-word in the normal subject is not accidental but has deep reasons, like all the so-called disturbances occurring in the experiment. Apart from these rare cases in normal subjects, in which the stimulus-word is each time quickly repeated in a low voice because of a general self-consciousness, this disturbance mainly occurs only at those points where an emotional charge from the previous reaction perseverates and hinders the following associations. In hysterics I have also seen that the complex-constellating stimulus-word tends to be repeated in a questioning tone.[20] These observations teach us that those places where repetitions of the stimulus-word occur are not at all unimportant in normal

subjects. For epilepsy, however, other mechanisms may also have to be considered. In this case the first four stimulus-words were repeated, the fourth, *to assume*, even three times. Then there was nothing repeated until the fifteenth, *intention*.[21] At the beginning a general self-consciousness is likely. In *assume* perhaps the “difficulty” of the word can have played a part; the same applies to *intention*. Both, moreover, have extraordinarily long reaction-times (23.2 and 13.0 secs.) which exceed by far those of other reactions. Perhaps then the repetition of the stimulus-word is not simply to be explained by the “difficulty” of the word, but could have been brought about by a perseverating emotional charge. The preceding reaction is *I am tired—yes, tired—the body is tired*: 3.0; the following reaction-time is 13.0.

[542] Apart from the content, the word *yes* already points to the existence of a stronger feeling-tone. The subsequent repetition of the stimulus-word appears in 19, *fruit*. The reaction preceding this is *am strong, that is strong*: 4.6 (fR-T 7.0).[22] 21, *sail* is repeated. Preceding reaction: *to work hard means to create*: 3.6 (fR-T 6.8). 22, *modest* is repeated. Preceding reaction: *a sail is a sailing boat on the water*: 6.8 (fR-T 9.0).

[543] Here we have two stimulus-word repetitions immediately following one another, whereby the reaction-times progressively increase: 3.6—6.8—9.0.

[544] The reaction to *sail* is a linguistic mishap (in my investigations into reaction-times, linguistic slips have proved to be complex-characteristics). At the near end of the scale is *to work hard*, an emotionally charged, probably egocentric reaction. The third reaction (22) is *yes, man is modest when he has learned something*. It is not difficult to see here a relation in the content to *to work hard*. The assumption that the emotional charge of *to work hard* has perseverated behind the linguistically disturbed reaction and constellated R.22 is therefore not unlikely.

[545] 47, *market* is repeated. Preceding reaction: I *am merry, I am gay*: 3.6 (fR-T 7.0). 51, *carriage* is repeated. Preceding reaction: *I am free—I am a free citizen, it would be nice, if only it were true:* 4.0 (fR-T 4.4).

[546] With the exception of the first four reactions most of the other repetitions of stimulus-words coincide with reactions that immediately follow egocentric associations. The reaction-time in these cases is mostly abnormally prolonged. To avoid being unduly long-winded I shall not bring any further evidence for this fact; I can, however, give an assurance that, with only very few exceptions,

all the other repetitions of stimulus-words took place near strong emotional charges.

[547] In several reactions a certain linguistic awkwardness was noticed. One is tempted, in analogy with imbecility, to make the epileptic mental defect responsible for these faulty formations. We know, however, another source for slips of the tongue: namely, the strong emotional charge of a complex aroused by the stimulus-word. In my communication on reaction-time in association experiments I shall quote a number of examples from which it can be seen how reactions are influenced in normal subjects by an emotionally charged complex. Apparently quite casual slips of the tongue, which the subject himself hardly notices, prove to be meaningfully determined products of the mixture of two competing ideas.[23] Before therefore ascribing the linguistic mishaps to mental defect it is advisable to investigate whether perhaps the mechanism discovered in the normal subject is here too the cause of the incorrect sentence or word-construction. Amongst the associations quoted here, there are three linguistically incorrect ones. I am pairing each of these three associations with the immediately preceding ones (the incorrect construction is given in italics):

18. strong	am vigorous, that is, strong	4.6
19. fruit	(stimulus-word repeated) this is a fruit, a *tree-fruit*	7.0
20. to create	to work hard means to create	3.6
21. sail	(stimulus-word repeated) *a sail is a sailing boat* on the water	6.8
33. bed	sleeping—I have the bed for	3.0
34. worthy	(stimulus-word repeated) that person is worthy *to whom him honour is due*	94

[548] These three faulty constructions have in common:

1. The stimulus-word of the faulty association was each time repeated.

2. Every one of the incorrect reactions has a reaction-time not only higher than that of the preceding reaction but prolonged beyond the average of the others.[24]

3. Two of the incorrect associations follow emotionally charged reactions: for the third this is at least probable according to the content and the analogy with similar cases.

[549] These observations give us so many starting points for an explanation that we may hardly assume mental deficiency to be the cause of the incorrect

constructions.

[550] From these observations we can see that a specific epileptic mechanism can be found neither in the numerous repetitions of the stimulus-word, nor in the faulty constructions of the sentences. It is, however, debatable whether anything specifically epileptic can be seen in the intensity of these otherwise normal processes. Here perhaps the reaction-times, a valuable aid for judging emotional processes, can give us some information.

[551] All time-averages given here are “probable means.”[25] The time measurements for the subject give 4.2 seconds as a general probable mean (uneducated normal person: 2.0 secs.). The general reaction-time is thus more than twice as long as that of corresponding normal subjects. This mean, however, is only a “gross” figure; it is composed of several unequal magnitudes. As I shall show in my later publication, reactions complicated by feelings are usually prolonged. If therefore there are many such reactions the general mean may under certain circumstances be strongly influenced. If we now eliminate all those reactions that, according to the criteria already given, are remarkable because of their feeling-toned egocentric contents and also those reactions that immediately follow these, then we obtain 3.8 secs. as a probable mean for all the assumedly uncomplicated reactions, while the probable mean for those eliminated is 4.8 secs.

[552] Thus the feeling-tone makes a difference of 1.0 sec. This state of affairs is not very different from that of the normal. As we have seen in several examples, there is frequently a considerable difference between the times of feeling-toned associations and those of the reactions immediately following them. We therefore investigate separately the time of these two groups. As a mean for the reactions containing a feeling-toned idea we have 3.6 secs., a figure 0.2 secs. lower than the mean for associations not feeling-toned; for the associations immediately following those that are feeling-toned, however, there is a mean of 5.8 secs. This unusually high mean, which exceeds that for the uncomplicated reactions by not less than 2.0 sec, expresses the important fact that the feeling-tone inhibiting the reactions perseverates from the critical reaction and exerts its main influence on the following reaction. Thus the effect of the feeling-tone inhibiting the reaction cannot as a rule be demonstrated in the critical reaction but only in the following reaction. One must therefore assume that in this case the feeling-tone does not properly set in until after the critical reaction, increases very gradually, and then decreases slowly, still inhibiting the following reaction. This state of affairs appears the more remarkable when we

remember that the experimenter has to write down the reaction, to read the stop-watch, and to call out the next stimulus-word, and that the writing down of the reaction, which may be rather long, takes most of the time. I also tried to make similar observations about the associations of normal subjects. For this purpose I took the associations of a case of whom I possess a most detailed analysis, so that I was fully informed as to all complex-constellated associations. The probable mean of all associations not complicated by feelings is 1.2 secs. The mean of the feeling-toned reactions is 1.6 secs. The mean of the reactions immediately following the feeling-toned ones is 1.2 secs. This equals the mean of the uncomplicated reactions. If, therefore, in the mentally normal subject the complex-arousing stimulus-word is followed by a reaction-time on average 0.4 secs. longer than that of the immediately following or irrelevant stimulus-word, this only means that in the normal subject the feeling-tone sets in much faster and subsides again incomparably faster than in our epileptic; thus the average reaction-time of the following association is unimpaired in the normal subject, whereas in our epileptic, as we have seen, the reaction-time for the following critical association is unusually prolonged.

[553] This important and interesting peculiarity appears to be of a pathological nature; how far it is typical for epilepsy has to be learned from the further study of our vast material.

[554] There seems to be something characteristic for our case in this phenomenon, because one can also assume the existence of such an enormous emotional process from the quality of the associations. I have repeatedly pointed out the fact that the subject frequently emphasized his reactions with his voice as well as also sometimes with words giving expression to some feeling (e.g., *hot / it's too warm, too hot; tired / I am tired—yes, tired—the body is tired;* etc.). This peculiar form of reaction also seems to indicate that the feeling-tone sets in slowly and increases slowly, in this way releasing even more associations in a similar direction. It is most likely that the feeling-tone in the epileptic is of greater intensity than in the normal subject, which again is bound to prolong the feeling-tone. It is, however, difficult to say whether the epileptic's feeling-tone is necessarily abnormally prolonged.[26]

[555] In my analytic investigations into the reaction-times of normal subjects I was able to demonstrate the existence of one or more feeling-toned complexes of ideas that constellate a large number of the associations. I have already pointed out that in our epileptic also there exists a complex that constellates

many of the associations. It is the complex of the illness. The following associations may be related to this complex:

5. pain	because I am ill	4.2 (fR-T 5.8)
14. tired	I am tired—yes, tired—the body is tired	3.0 (fR-T 13.0 Rr)[27]
18. strong	am vigorous, that is, strong	4.6 (fR-T 7.0 Rr)
43. blood	every man has, every animal only good or bad, that is the difference	3.4 (fR-T 6.0 Rr)
46. merry	I am merry, I am gay	3.6 (fR-T 7.0 Rr)

A more remote constellation might be:

11. air	this is the air—healthy or unhealthy	2.2 (fR-T 5.0)
36. to visit	I visit a patient	4.8

The reaction following is:

37. locksmith	I am a locksmith, an artisan	2.8

[556] Because of his illness the patient was hospitalized, a fact that made a great impression on him. He feared especially that he might never be discharged, nor be able to work and earn his living any longer. He was also homesick. The following reactions perhaps refer to this aspect of the complex:

20. to create	to work hard means to create	3.6 (fR-T 6.8 Rr)
35. danger	I am in danger, in danger of life	4.2 (fR-T 4.8)
50. free	I am free—I am free, I am a free citizen, it would be nice if only it were true	4.0 (fR-T 4.4 Rr)
60. to wish	I wish you luck in the New Year	3.0 (fR-T 4.6 Rr)

Regarding this last reaction, it must be added that the associations were taken before Christmas—at a time, therefore, when sensitive patients suffer twice as much from hospitalization.

[557] These few examples may suffice to show that quite a number of associations are constellated by a feeling-toned complex. This state of affairs in itself is not at all abnormal, since the associations of normal people are also often constellated by such complexes.

SUMMARY

[558] I. In common with the associations of normal persons:

(*a*) The patient adapts himself to the meaning of the stimulus-word in the same way as uneducated subjects. Therefore there are no superficial word associations.

(*b*) The associations are partly constellated by an illness-complex.

II. In common with the associations of imbeciles:

(*a*) The adaptation to the meaning of the stimulus-word is so intense that a great number of associations has to be understood as "explanation" in the sense of Wehrlin's paper.

(*b*) The associations are in sentence-form.

(*c*) The reaction-times are considerably prolonged, compared with the normal.

(*d*) The stimulus-word is frequently repeated.

III. Peculiarities compared with normal and imbecile subjects:

(*a*) The "explanations" have an extraordinarily clumsy and involved character which is manifest particularly in the confirmation and amplification of the reaction (tendency to completion). The stimulus-word is frequently repeated in the reaction.

(*b*) The form of the reaction is not stereotyped, apart from the egocentric form that occurs particularly often (31%).

(*c*) Frequent emotional references appear rather bluntly (religious, moralizing, etc.).

(*d*) The reaction-times show the greatest variation only after the critical reaction. The abnormally long times are therefore not to be found with particularly difficult words, but in places determined by a perseverating emotional charge. This permits the conclusion that the feeling-tone probably sets in later and lasts longer and is stronger in the epileptic than in the normal subject.

[559] In conclusion I beg to remark that the value of my analysis lies only in the case-material and that therefore I do not dare to draw any general conclusion from it. There are many forms of epilepsy that may have quite different

psychological characteristics. Perhaps the fact that my case is complicated by a fracture of the skull sets it apart.

THE REACTION-TIME RATIO IN THE ASSOCIATION EXPERIMENT[1]

[560] As the subject of the present investigation I have chosen the ratio of the time-interval between calling out the stimulus-word and the patient's verbal reaction. I am calling this period simply the *reaction-time*, knowing that it is a matter of a compound whole that can be divided, not only deductively but also empirically, into numerous components. I am not going to attempt an analysis of this kind for it could only be a matter of hypotheses that would have to be supported, quite unjustifiably, by anatomical data. The components of our reaction-time are known to us only in part, and careful examination must necessarily show them to be tremendously complicated, as we can see from the following summary given by Claparède:[2]

1. Transmission of sound to the ear of the recipient.
2. Neural conduction to the auditory centre.
3. Word-recognition (primary identification).
4. Word-comprehension (secondary identification).
5. Evocation of the associated image, i.e., pure association.
6. Naming of the idea evoked.
7. Excitation of the motor speech-apparatus or the motor-centre of the hand when measurement is made by means of a Morse telegraph key.
8. Neural conduction to the muscle.

[561] A purely superficial examination of these eight factors shows that only a few of the most important processes are stressed. The innumerable possibilities of intra-cerebral process are by no means exhausted in this summary.

[562] So far as we know these components, they are of very short duration, even the longest of them should not exceed 50 σ (Ziehen). Some of these components might, in normal circumstances, be of fairly constant duration, as for instance the time of the neural conduction, of the excitation of the centres, etc. In any case, their variations will occur only within relatively narrow limits. The variation of the identification periods, however, are greater, and the longest of all are the actual association-time and that of the verbal formulation of the

reaction. Thus, in the association experiment, the latter factors will be of the greatest importance.

[563] Anyone conversant with the association experiment knows how wide are the limits within which reaction-times vary. In our experience times of up to six seconds are by no means rare, even with quite normal subjects. The great variability of the times gives us the necessary lead for establishing a *method of measurement*. So long as we have inadequate knowledge of the causes of the variations, small differences cannot tell us anything; we do not therefore need a complicated experimental set-up in order to measure the intervals in one-thousandths of seconds, for we can safely ignore small differences so long as the causes of the greater variations are still hidden. Quite apart from the fact that the complicated methods of exact time-measurement do not reveal more than measurements taken with a ⅕-second stop-watch, there are weighty arguments against the use of complicated apparatus like labial keys[2a] and megaphones or of dark-room methods. Considering that Mayer and Orth[3] even thought it necessary that the eyes should be closed throughout the experiment, to avoid distracting sensations, surely the apparatus mentioned do not contribute anything to the simplification of the experiment or the prevention of disturbing influences. In any case, inexperienced subjects should not be used in experiments of this kind if one is not to risk gross distraction. Finally, in the case of psychotics exact measurements are impossible.

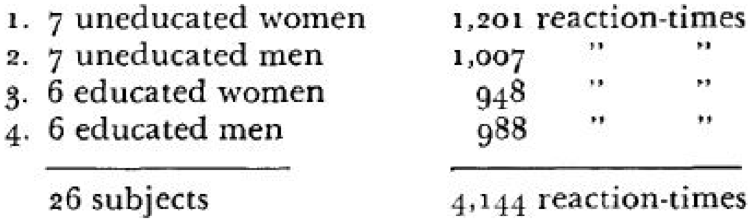
[564] For this reason, measurement with a 1/5-second stop-watch not only appears entirely satisfactory, but has been proved adequate by several other writers in numerous experiments. Mayer and Orth worked with a 1/5-second stop-watch, so did Thumb and Marbe,[4] Wreschner,[5] Sommer, and others. Claparède[6] holds that this is adequate in all experiments regarding successive associations. Besides the fact that the watch is easy to handle, a further special advantage is that the second hand disturbs the experiment as little as possible, a factor which is particularly valuable in experiments with uneducated subjects, who are easily upset.

[565] Considering the great differences in the times, it means little that the times measured are all somewhat too long. All of us who have worked with a stop-watch know too that it functions with only limited precision, since the stopping mechanism does not always hold the second-hand at the exact place it was at when the button was pressed. There are also certain variations in the personal equation that can influence the measurement. In spite of numerous imponderables, we can still, at least in my experience, assume that the

measurements are accurate to approximately 1/5 second, i.e., 200 σ. This small disadvantage has not so far had any adverse effect on our experiments.

[566] The material that forms the basis of this investigation consists of time-measurements that were taken by Riklin and myself[7] during association experiments with normal subjects. Out of 38 cases, whose associations we have already discussed, reaction-times were taken in 26. In about half the cases Riklin did the timing. The personal differential in the measurements of the two experimenters can, as we have established by means of control experiments, be determined at less than 1/5 second and can, therefore, be considered unimportant.

[567] Here are the number and analysis of the measurements:



1.	7 uneducated women	1,201	reaction-times
2.	7 uneducated men	1,007	" "
3.	6 educated women	948	" "
4.	6 educated men	988	" "
	26 subjects	4,144	reaction-times

A. *The Average Duration of an Association*

[568] In his studies of associations, Aschaffenburg says: “The fact that the difference between duration of the association of normal subjects and that of others, which lies between 1,200 and 1,400 σ, can be as much as 50 per cent is of the greatest importance. This brings home to us how little value can be attributed to the absolute duration.”[8]

[569] Aschaffenburg bases this opinion on the observation that the reaction-time is subject to very considerable individual variations. Correspondingly, the data recording the average duration of association contained in the literature show wide discrepancies. Féré,[9] for instance, found an average of 700 σ in men, 830 σ in women. Galton[10] gives 1.3 seconds as the average, and Trautscholdt’s[11] figures range between 1,154 and 896 σ.

[570] These examples should suffice to show how little agreement there is between the various writers. The differences can be reduced to the following points:

(1) The methods of measurement differ according to the apparatus used and other experimental conditions.

(2) The degree of practice of the subject is variable.

(3) The methods of computing the mean vary. In practice, only two methods of computation are in use:

a. The arithmetical mean.

b. The probable mean (Kraepelin).

[571] In view of the fact that excessively long reaction-times frequently occur in the association experiment, the application of the arithmetical mean does not appear advisable in that by this method the high values influence the otherwise quite low average values in a most disturbing and possibly quite misleading manner. This can be avoided by using the method of the probable mean, which consists in arranging the figures in the order of their numerical value and taking that nearest the middle. By this means the influence of excessively high values is eliminated. In by far the largest number of cases the probable mean is for this reason lower than the arithmetical mean. For example, three of my subjects show the following values:

Probable mean	1.8	2.0	1.6
Arithmetical mean	2.8	3.0	3.6

As the example shows, such differences can influence the general mean to a considerable extent. It is therefore not a matter of indifference which method of calculation is used. Ziehen's "representative value," which demands fairly intricate calculations, should, for this reason, not meet with much approval, although it does make possible a very just appraisal of the individual figures. Finally, the highest value depends on external contingencies, and can be used only in certain conditions.

[572] For these reasons, the probable mean appears to be the method with the most to recommend it for quickly deriving averages from large numbers of figures.

(4) The number of subjects used by the early writers on this subject was mostly too limited, and their selection too one-sided.

[573] My endeavours have not been directed towards discovering absolute means, but merely approximate figures which can, to a certain extent, give us the levels of the values of normal subjects from varying social strata. As I believe that the association experiment, carried out in approximately the way it has been practised in this clinic for several years past, will play an important role in the future diagnosis of mental illness, it seems to me to be most important to find

general normal mean-values which can form a firm basis for the assessment of pathological values.

[574] The general mean-value of the duration of an association seems to be 1.8 seconds. This figure was arrived at in the following way: First of all, the probable mean for each of the twenty-six subjects was calculated, and then the arithmetical mean was derived from the individual values. This method was chosen because twenty-six subjects represent a very modest number, and it would be unjust to exclude the individual values from the calculation through the application of the probable mean.

[575] This mean shows a fairly long duration of the reaction-time; it is considerably higher than the values given in the literature. The causes of this lengthening can be attributed to the following:

(1) The points mentioned above (measurement with a stopwatch, unpractised subjects, who in part come from lower social strata).

(2) The majority of the subjects are Swiss, the significance of which in our acoustic/linguistic experiments has already been emphasized in our previous contribution, which the reader may refer to.[12]

[576] The varying data show what the interpretation of the values depends on. The variability of the mean is most easily demonstrated by classifying the subjects according to certain simple criteria and comparing the figures of the individual groups.

B. *Sex and Reaction-time*

[577] As already mentioned, Féré has given longer times for women than for men. This result is confirmed by our figures:

men	1.6 secs.
women	2.6 secs.

These values indicate that women reacted considerably more slowly in our association experiments. It must be pointed out in criticism of this result, however, that the educated women among the subjects approach the educational level of the educated men, whereas, on the other hand, the cultural level of the uneducated women is inferior to that of the uneducated men. As may be known from Ranschburg’s[13] and our own earlier investigations,[14] uneducated subjects, and especially the women among them, produce much higher figures than educated subjects, and give a considerably higher percentage of internal associations, while purely linguistic associations are very much less prominent. According to Ziehen's[15] observations on children, associations by means of internal connections (semantic relationships) are distinguished by the longer reaction-times, whereas verbal associations need the shortest times. This fact stressed by Ziehen, was denied by Aschaffenburg,[16] since he finds on the basis of his observations "that no form of association is characterized by especially notable differences of duration." The figures given by Aschaffenburg can, it is true, not be interpreted in any other way, but they can perhaps be explained by his one-sided selection of subjects. Ziehen's claim that "images that are related to each other externally, such as, for instance, rhyming words" are reproduced more quickly, is in full accord with everyday experience.

[578] This point, too, should be taken into account in explaining the longer association-times of women. Whether this explanation is sufficient, further consideration will tell. In any case, we must investigate the influence of education before discussing a possible sex difference in the reaction-times.

C. *Educational Level and Reaction-time*

[579]

	Educated Subjects		*Uneducated Subjects*		
Men	1.3	secs.	1.8	(1.6)[17]	secs.
Women	1.7	”	2.2		”
Average	1.5	”	2.0	(1.9)	”

[580] Our previous investigations demonstrated that uneducated subjects produce more internal associations than the educated. The ratio of internal to external associations is 43 : 53 per cent with uneducated and 36 : 59 per cent with educated subjects. One is therefore tempted to connect the differences in the reaction-times with these ratios and to state: the smaller number of internal associations with educated subjects corresponds to the shorter reaction-time, and vice versa, the greater number of internal associations with uneducated subjects corresponds to the longer reaction-time.

[581] However plausible this hypothesis may appear, particularly in view of Ziehen's statements, consideration of the figures of the different sexes does show, however, that the position is not so simple. On closer consideration of the educational levels of the subjects, it must be expressly mentioned that the educational difference between the educated and the uneducated is incomparably greater than that between educated men and women, so that it is

quite incomprehensible why the time-difference of 0.4 seconds is the same between educated men and women as between educated and uneducated subjects. Moreover, the reaction-time of 1.7 seconds for educated women, as against 1.3 for educated men, does not correspond at all to the percentage-ratio of internal and external associations; for the educated women show 35 : 61 per cent and the men only 36 : 56 per cent. Similarly, the time-difference of 0.4 and 0.6 seconds respectively between uneducated men and women in no way corresponds to the difference in educational level between the two sexes in the uneducated group. In both cases there remains a time-difference against the female which in no way corresponds to any variation in educational level. If we take the time-difference of the two groups of men on the one hand and of women on the other, the difference in educational standards is a sufficient explanation, as has already been very clearly shown in the ratio of the association-qualities one to another. The observations of Wreschner[18] and Wehrlin[19] also lend support to this assumption, as they have demonstrated a general slowing down of associational activity in cases of pathological deficiency in intelligence and education (congenital feeble-mindedness). Wehrlin demonstrates an increased incidence of internal associations along with longer reaction-times.

[582] Whereas the uneducated women produce slightly more internal associations than the men, the position with regard to educated men and women is actually the reverse, in that the educated women have fewer internal associations than the men; nonetheless, there is a time-difference between the sexes that is greater than that between the educated and uneducated. As we have seen, we can account for this neither by a greater number of internal associations, nor by the small difference in education. Here a new factor seems to be at work, presumably the difference of sex.

[583] The justification of this hypothesis will be dealt with below. Before we approach this task, however, we must investigate the influence that the individual stimulus-word has on the reaction.

D. *The Influence of the Stimulus-word on the Reaction-time*

[584] The preceding investigations into association-times have been principally concerned with the connection between the quality of the association (i.e., the reaction) and its duration. Trautscholdt attempted to establish certain connections and claims, among other things, that verbal associations take the shortest time. Ziehen’s and Aschaffenburg’s observations have already been

mentioned. We must now find out whether the influence on the reaction-time of the two components of the association—the stimulus-word and the reaction—cannot be examined separately. Only an extensive material can be expected to yield definite information. For this reason I have already attempted, with Riklin, to demonstrate the influence of the stimulus-word on the quality of the reaction. Here certain regular occurrences appeared, namely:

[585] (1) The grammatical form of the stimulus-word has a considerable influence on the form of the reaction, and the form of the reaction is indeed determined by it; the subject tends to clothe the reaction in the grammatical form of the stimulus-word.[20] Individual figures showing this tendency vary greatly. My stimulus-words, which consist of 60 per cent nouns, 18 per cent adjectives, and 21 per cent verbs (the various parts of speech are well mixed up in order to avoid a continuation of one form of reaction), have given these results:

[586] Individual figures of grammatical agreement vary between 26 per cent and 95 per cent. The average figure for educated subjects is 51 per cent and for the uneducated 59 per cent. Thus the uneducated show a somewhat clearer tendency to allow themselves to be influenced by the form of the stimulus-word. (This holds good not only for the grammatical form but also for the number of syllables and alliteration!)

[587] (2) The tendency to agreement in grammatical form is limited by the influence of the law of frequency. In speech, adjectives and verbs occur only about half as often as nouns.[21] The noun, therefore, has a higher frequency-value, so that the probability of the reproduction of a noun is greater than that of an adjective or verb.

[588] In our experiments noun stimuli were followed, on an average, by 73 per cent nouns (Aschaffenburg: 81 per cent). As verbs and adjectives have a lower frequency-value, their influence on the form of the reaction will be correspondingly less. Our experience confirms this supposition: verb stimuli were followed, on an average, by 33 per cent verbs. The number of nouns is on an average 49 per cent, it has thus been lowered through the tendency to agreement in grammatical form. A somewhat stronger influence is exerted by adjective stimuli, which are followed by 52 per cent adjectives. The number of nouns was reduced to a mean of 44 per cent through adjective stimuli. From these facts it appears that the frequency of nouns can be reduced, on the average by about half, by using verbs and adjectives as stimulus-words.

[589] (3) From our earlier investigations[22] it appears that the quality of the association is influenced to quite an extent by the grammatical form of the stimulus-word. Whereas, for example, with uneducated women the ratio of internal to external associations is 1 : 1.06, the ratio of associations which follow adjectives in particular is 1 : 0.62 and that of associations following verbs is 1 : 0.43. The number of internal associations to verbs and adjectives thus increases considerably. The same phenomenon is also found in educated subjects, but in a smaller degree. The increase in internal associations seems to be accounted for by the fact that, by virtue of the lower frequency-value of verbs and adjectives, fewer common word-sequences exist with these than with nouns. For this reason associations following verbs and adjectives are much less canalized and require a greater concentration, as a result of which, of course, semantic relationships emerge more readily than superficial and more external connections.

[590] Thus we can see that more internal associations follow verbs and adjectives than follow nouns; according to observations made by Ziehen, who has found higher time-values for semantic relationships, it is to be expected that on the average verbs and adjectives should be followed by higher time-values than nouns. As, however, nouns refer to images that are to be evaluated differently, and that can to a great extent influence the reaction-time, they have been classified as concrete and abstract. One further reason was that uneducated subjects especially are easily startled by abstract terms.

[591] The probable mean-times for all subjects are as follows:

Concrete nouns	1.67 secs.
Abstract nouns	1.95 ”
Adjectives	1.70 ”
Verbs	1.90 ”

These figures correspond to our expectations: reactions to verbs and adjectives show a longer time than those to concrete nouns. The longest time of all is taken for abstract terms, which was also to be expected.

[592] This picture becomes more interesting when the subjects are divided into groups.

Probable Mean of the Reaction-times to Concrete Nouns etc. as Stimulus-words

	UNEDUCATED		EDUCATED	
	Women	Men	Women	Men

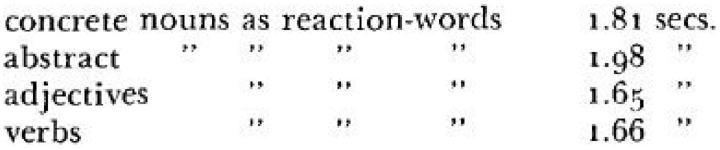
Concrete nouns	2.0	1.7	1.6	1.4
Abstract nouns	2.8	1.9	1.8	1.3
Adjectives	2.2	1.7	1.7	1.2
Verbs	2.4	2.0	1.9	1.3

[593] The table[23] shows that uneducated people have longer reaction-times than educated ones. The longest time occurs for abstract ideas with uneducated women, whereas with educated men these words need an even shorter time than concrete ideas. It is striking that, in contrast to all other subjects, educated men have the longest reaction-time in response to concrete ideas. This fact is significant in so far as it shows that the influence of the stimulus-word on the duration of the association does not consist merely of those elements just mentioned. If we compare the figures of this group with the values that Aschaffenburg has found with similar subjects, it appears that the figures found by using a stop-watch are similar to those obtained by labial key and chronoscope.[24]

E. *The Influence of the Reaction-word on the Reaction-time*

[594] In the above discussion we have explained how the reaction-time is affected by the stimulus-word's being a noun, adjective, or verb. We must now find out what happens to the reaction-time when the reaction-word is a noun, adjective, or verb.

[595] The probable mean-times of all subjects are as follows:



concrete nouns as reaction-words	1.81 secs.
abstract ” ” ” ”	1.98 ”
adjectives ” ” ”	1.65 ”
verbs ” ” ”	1.66 ”

[596] If we compare this table with the earlier one, which gave the mean-times for the corresponding stimulus-words, it appears that in both cases abstract terms produce the longest intervals (1.95 and 1.98 seconds); if the reaction-word is a concrete one a longer time is taken than that produced by a concrete stimulus-word (S. 1.67; R. 1.81 seconds). This difference might be due to the fact that there are many current word-compounds containing nouns, whereas noun following noun signifies an inner relation, or at least an association by coexistence (which, by the way, in uneducated subjects appears as an internal association; cf. our earlier investigations).[25] Under the heading "concrete nouns as reaction-words" numerous internal associations are crowded together, which is probably the cause of the long reaction-time. The opposite can be seen with

verbs and adjectives as reaction-words. Their average values are less, compared with those on the earlier table (1.70, 1.90 : 1.65, 1.66) because under these headings, particularly in that of verbs, current word-compounds abound.

[597] The probable mean-values of the individual classes of subject are these:

Probable Mean-times for Concrete Nouns etc. as Reaction-words[26]

	UNEDUCATED		EDUCATED	
	Women	Men	Women	Men
Concrete nouns	2.2	1.85	1.7	1.5
Abstract nouns	2.7	2.0	2.0	1.4
Adjectives	2.0	1.7	1.7	1.2
Verbs	1.9	1.7	1.8	1.3

[598] These relatively lower values for adjectives and verbs are shown here in all four groups. Here, as in the previous table, the uneducated women again show the highest figures. The relatively high figures for concrete nouns are striking. The fact already mentioned in the previous section, that cultured men take their longest time to react with concrete nouns, is also in evidence here. An explanation of this is perhaps to be found in the circumstance that in this group very many semantic relationships (causing delay) occur.

F. *The Influence of the Quality of the Association on the Reaction-time*

[599] As we have seen, Aschaffenburg's investigations into the influence of the quality of the association on the reaction-time did not lead to unequivocal results; Ziehen's success, already mentioned, is therefore all the more encouraging. I too have conducted some research on this subject in which I have confined myself to the three principal groups of our earlier classification: internal, external, and sound reactions. This has produced the following average figures:

	UNEDUCATED		EDUCATED	
	Women	Men	Women	Men
Internal associations	2.8	1.9	2.1	1.6
External ”	1.9	1.7	1.8	1.3
Sound reactions	2.6	2.4	2.0	1.8

[600] There is a distinct difference between the reaction-times for internal and external associations in that external associations take up decidedly less time. A different picture is presented by sound reactions, where one would expect the

shortest times, as sound reactions quite rightly are to be regarded as the lowest and least valuable form of association, and for that reason could be produced in the shortest time. In practice, however, the situation is obviously not as simple as one would surmise in theory. As I have so often observed, the most superficial sound reactions very often take a very long time. As a rule, in my experience, sound reactions are usually abnormal reactions and their formation is mostly attributable to some kind of distracting influence; of what kind this disturbance usually is, the following chapter will show.

G. *Prolonged Reaction-time*

[601] To demarcate the concept of a "prolonged" reaction-time, I call any time prolonged that takes longer than the probable mean for the subject concerned. Thus, if the average for the individual subject is 2.5 seconds, then 3 seconds is overlong.

[602] Let us first recapitulate what is so far known of the causes that (of course, only in our experiments) lengthen reaction-times:

(1) Certain grammatical forms of the stimulus and reaction-words.

(2) Semantic relationship between stimulus- and reaction-words.

(3) The rarity or difficulty of the stimulus-word (abstractions!).

(4) Ziehen[27] states the remarkable fact that (in contrast to generic reactions) individual associations prolong the reaction-time.

(5) Mayer and Orth[28] in their experimental studies on associations found that the reaction-time was lengthened when the active will intervenes between stimulus-word and reaction. If between the stimulus-word and the reaction an emotionally charged conscious content occurred, the reaction-time was on the average considerably prolonged, as compared to those of all the other reactions. Contents charged with unpleasure[29] have an especially delaying effect.

(6) In our earlier investigations[30] on the associations of normal subjects, we pointed out that abnormally long reaction-times occur particularly when the stimulus-word touches on a feeling-toned complex, i.e., a mass of images held together by a particular affect. So we were able not only to confirm the observations of Mayer and Orth, but also to demonstrate in various cases that: (*i*) The cause of several, or even very many, long reaction-times is generally the complex, and (*ii*) of what type the complex is.

[603] It appears to us to be of the utmost importance that prolonged reaction-times can indicate the presence of feeling-toned complexes. So here we may perhaps have a means of discovering by a short and simple examination certain things that are individually extraordinarily important—namely, those complexes that are distinctive features in the psychology of the personality. This would also be of great assistance in pathology, since in this way we could find—in cases of hysteria, for example—valuable pointers to the pathogenic complexes of images of which the hysterical patient is not always aware.

[604] To clarify matters more fully, I have, with the help of educated subjects who are also reasonably introspective, made a thorough analysis of individual associations, to which I should now like to refer.

[605] *Subject No. 1*: a married woman who placed herself at my disposal in a most co-operative manner and gave me all the information I could possibly need. I am reporting on the experiment as fully as I can so that the reader may picture it as completely as possible.

The probable mean reaction-time for this experiment was 1.0 second.

1. head	-scarf	1.0
2. green	grass	0.8
3. water	-fall	1.0
4. to pierce	to cut	0.8
5. angel	-heart	0.8

Up to this point the reactions followed without the slightest emotional charge, quite smoothly and impassively. R.5 is striking; the subject can for the moment give no justification or explanation of how she came to *-heart*, which she feels is a word-compound. Suddenly through her mind flashes “Engelhard,” a name that had always been familiar to her. This is therefore an indirect association of the type known as displacement by sound similarity. We now come to the question of why this indirect association should have occurred so suddenly. As a result of our earlier investigations,[31] we find that under certain circumstances indirect associations are more often found with a state of disturbed attention. It may therefore be assumed that the distraction of the subject’s attention can produce indirect associations. The subject repudiates any disturbance coming from without. Nor is she aware of any inner disturbance. When consciousness cannot furnish any data, an unconscious excitation may still have disturbed the reaction. The stimulus-word *angel*, however, was for this subject not emotionally hinged. As we know from earlier investigations, a preceding emotionally charged association can leave a trace in the unconscious and unconsciously constellate[32] the reaction, particularly when the preceding association had a strong feeling-tone. R.4, *to cut*, had evoked in the subject some slight anxiety, the image of blood,[33] etc. The subject is pregnant and now and again has feelings of anxious anticipation. Whether the image *blood* had determined the reaction *heart* I shall not try to decide.

The feeling-tone of *to cut* was according to the subject so slight and secondary that the connection did not strike her. It was for this reason that the extension of the reaction-time usual in similar situations failed to occur.

6. long	short	0.8
7. ship	sailing	0.8
8. to plough	field	1.0
9. wool	silk	1.0
10. friendly	charming	1.2
11. table	chair	1.2
12. to carry	to lift	1.2
13. state	to make	1.2
14. insolent	snobbish	1.2 (*trotzig/protzig*)

(This rhyme is a constellation. The subject recalls that she once read it on one of my association-forms.)

15. to dance	to leap	0.8
16. lake	sea	0.8
17. ill	well	1.2
18. proud	fiery	1.2

The last two reactions show some (albeit slight) feeling-tone.

19. to cook	to learn	0.8
20. ink	black	1.0
21. evil	good	0.8
22. needle	thread	1.0
23. to swim	to learn	0.8

Here R. 19 recurs with the same short reaction-time. The subject admits that she has not learned much about cooking and had never learned to swim at all well.

24. journey	Berlin	1.2

Constellation of a journey some months previously, the date of which, by the way, approximately coincides with the start of her pregnancy.

25. blue	heaven	0.8
26. bread	to eat	1.2
27. to threaten	fist	1.2
28. lamp	green	1.4

Here we find the first rather long time. The subject had hardly noticed her hesitation, nor had she been aware of any particular feeling-tone. The previous stimulus-word, *to threaten*, does, however, have something insidious to many subjects. If we think of the feeling of anxious anticipation mentioned earlier, we perhaps have a clue to the elucidation of this extended reaction-time; it is perhaps a perseveration. The feeling-tone in such cases need not appear with the previous reaction. In our experience, affective processes always take longer than purely associative processes, both to appear on the surface and to take their course. The feeling-tone lingers on, as can be observed in certain hysterics.

The reaction *green* is a constellation from her *domestic* life (lamp-shade).

29. rich	poor	1.0
30. tree	green	0.8

Here we have the same reaction as 28 with a very short interval, a phenomenon that may be accounted for by the fact that associative processes that have just come into consciousness tend to return, i.e., can very easily be repeated.[34]

Our earlier investigations[35] have also taught us that repetitions of a reaction are frequently based on a particular feeling-tone, in that the repeated words are associated with a feeling-toned complex. The feeling-tone pervading such a word is the mechanism that evokes it again and again in appropriate circumstances.

31. to sing	can	2.4

A very superficial reaction, similar to *to learn* with *to cook* and *to swim*, with a strikingly long reaction-time. The subject is very musical, but has always regretted that she cannot sing, and indeed this has hurt her more than, for instance, her not being able to swim.

32. sympathy	to have	1.0
33. yellow	gold	1.0
34. mountain	to climb	1.0

35. to play	children	1.0
36. salt	salty	1.4

In this reaction the subject comes up against a certain inhibition for the first time, whereas all the earlier reactions had followed easily. The subject explained that at first she did not understand the word *salt* at all and had had to make a deliberate effort to grasp it. In spite of the prolonged reaction-time and the exertion of attention, a very superficial reaction followed, which is determined to a considerable degree by sound. The subject cannot explain this disturbance. Let us look again at the previous reaction, *children;* this belongs quite clearly to the pregnancy-complex; the feeling-tone has persisted and caused the disturbance.

37. new	old	1.0
38. custom	habit	1.0
39. to ride	to travel	1.0
40. wall	-maps	1.0
41. stupid	clever	1.0
42. exercise-book	book	1.0
43. to despise	*mépriser*	1.8

Once again a longer reaction-time and, also, a striking rendering of the reaction into French. The reaction is also very superficial and adds nothing new to the idea referred to by the stimulus-word.

To despise is, for the subject, accompanied by an unpleasant feeling-tone. Immediately after the reaction it occurred to her that she was momentarily afraid that her pregnancy might by its various effects cause her to lose her husband's regard. Then she immediately remembered a married couple who had at first been ideally happy and then had become estranged: the couple in Zola's novel *Vérité*. Hence the reaction's being in French.

These reminiscences, needless to say, were not conscious at the time of the reaction.

44. tooth	time[36]	1.0
45. correct	false	1.0
46. nation	faithful	1.4

Again a longer time with a slightly unpleasant feeling-tone. She thinks that some song contains the phrase "a faithful people," but has a feeling that there is something about it personally unpleasant to her.

The preceding reaction, which has no perceptible feeling-tone, is *false; loyal* is the opposite. This observation suffices to bring the subject to the correct explanation: the reaction *false* had stimulated her pregnancy-complex, and in particular her fear of her husband's estrangement.

47. to stink	to be scented	1.0
48. book	to read	1.0
49. unjust	just	0.8
50. frog	leg	1.2
51. to part	to avoid	0.8
52. hunger	thirst	0.8
53. white	black	1.0
54. ring	finger	1.0
55. to watch	to listen	1.0
56. pine	forest	1.0
57. dull	fine (weather)	1.0
58. plum	pear	1.0
59. to meet	sure	1.0
60. law	to keep	1.2
61. dear	man	1.2
62. glass	clear	1.0

The strong sound association of *clear* is probably also due to the previous reaction.

63. to argue	to quarrel	1.2
64. goat	bleats	1.2
65. big	little	0.8
66. potato	field	1.0
67. to paint	painter	1.0
68. part	piece	1.0
69. old	young	1.0
70. flower	red	0.6 (*Blume/rot*)

This notably short reaction-time is explained by the subject by the fact that the first syllable of the stimulus-word *Blu-me* had already caused that of *Blu-t* (blood); cf. 4 and 143. Here we have a kind of *assimilation* of the stimulus-word to the strong pregnancy-complex.

71. to beat	to stab	1.0

72. box	-bed	1.0
73. bright	brighter	1.4 (*hell/heller*)
74. family	father	1.4

These four reactions are interesting. It will be remembered that with 4 *to pierce/to cut* we came across the pregnancy-complex for the first time. Without the subject having had any idea that this reaction was important, we here have *to pierce* following immediately on the *Blu-me/Blut* association. The following R.72 also came quite smoothly without any feeling at all. The reaction itself is, however, striking. The subject, who occasionally visited our asylum, meant the deep beds used there—the so-called box-beds. She was somewhat puzzled by this explanation, because the expression "box-bed" was not particularly familiar to her. Following this somewhat unusual association, we have a sound association of relatively long duration, thus a phenomenon that we have already indicated earlier to be indicative of a complex. "Heller" (brighter) is the name of a person who was once important—though indirectly—to the subject. Quite probably no strongly emotional memories are connected with this name. There was only a very slight hesitation, implying a subjective feeling. For this reason, the supposition that the sound reaction is connected with the strange previous reaction does not seem to be entirely groundless. The reaction *bed* is later repeated with the clear impression of a word-combination in 199—*bone-bed (Knochen-bett*), a meaningless combination inexplicable to the subject; if we consider a change of sound in view of her pregnancy-complex, the association could be very significant—*Wochen-bett* (childbed).[36a] If we take this hypothesis as a basis, the above series is explained in the clearest way; again we have the pregnancy-complex with blood, operation, childbed; the feeling-tone here becomes obviously stronger and disturbs the following reaction (perhaps *bright* cannot be assimilated to the complex!); finally, we have *father*.

75. to wash	washerwoman	1.0
76. cow	stupid	0.8
77. strange	-ness	1.0
78. fortune	fortunate	0.6
79. to tell	mother	1.4
80. propriety	Ge-	1.2 (*Ge*-)
(*Anstand*)	usage	2.0 (*Sitte*)

R.78 is very short, which is rather striking in a stimulus-word that could easily have stirred up the complex. The following reaction, therefore, takes proportionately longer, 1.4 seconds, which up to now has been symptomatic of a complex. The reaction *mother* explains the prolonged time. R.80 is disturbed, not surprisingly, as the complex was so obviously touched; only after 2 seconds do we get the reaction *usage*, after the *Ge-* prefix first. In this the feeling-tone of *mother* still perseverates in the subject. The subject cannot find any connection between *propriety* and *Ge-*. Above all she cannot think what word she wanted to start with *Ge-*. We are thus dependent only on suppositions. With 79 the pregnancy-complex appeared again quite clearly. We have already seen on several occasions that it is characterized mainly by feelings of *anxiety* and apprehension. We have also already seen that the first syllable of a stimulus-word is assimilated to the complex (*bloom/blood);* is the first syllable of *Anstand* (propriety) = *Anst*, assimilated as *Angst* (fear) and then *Ge-* = *Geburt* (birth)? This hypothesis immediately struck the subject as near the truth. This construction may well appear to many to be made in the manner of the augurs; I would not record it here if I had not come across many analogous phenomena in both healthy and sick subjects.

81. narrow	-minded	0.6
82. brother	sister	0.8
83. to damage	to avoid	1.2 (*schaden/meiden*)

This is very reminiscent of 51, *scheiden/meiden* (to part/to avoid). Has *schaden* perhaps been repressed by the complex as too unpleasant and been assimilated as *scheiden?* Repressive assimilations of this nature frequently occur in hysterics. The subject is quite unable to explain this.

84. stork	to bring	3.4

This abnormal time is quite clearly caused by the complex.

85. false	cat	1.0
86. fear	to have	1.0
87. kiss	me	1.2

The emphasis on the ego in R.87 could perhaps also be determined by the critical reaction to 86.

88. conflagration	fire	1.2
89. dirty	yellow	1.0
90. door	closed	0.8
91. to choose	choice	1.2
92. hay	grass	1.0
93. still	quiet	0.8

94. scorn	derision	1.0
95. to sleep	to stay awake	1.0
96. month	May	1.0
97. coloured	blue	1.2
98. dog	cat	1.0
99. to talk	speak	1.0
100. coal	dust	1.0
101. moderate	drinking	1.0
102. lid	eye-	1.0
103. to suppose	to believe	1.2
104. ache	heart	0.8 (*Schmerz/Herz*)

This rhyme, which has a relatively short reaction-time, is stated by the subject to be a mere catch-phrase.

105. lazy	sluggish	1.0
106. moon	-calf	1.0
107. to laugh	to cry	1.0
108. coffee	to drink	1.0
109. wide	narrow	1.0
110. air	thick	1.0
111. to carry	to lift	1.0
112. plate	round	0.8

R.110 is somewhat unusual; it seems as if the constellation *wide/narrow* has had a particularly powerful influence. Does it perhaps echo through to R.112?

The next following reactions are entirely objective in character—neither the subject nor the observer noticed anything special about them. The times are never more than 1.2 seconds. We shall therefore pass them over.

143. blood	red	0.6
144. to let (a house)	to let	1.2
	to avoid	2.0
145. caution	leniency	1.0 (*Vorsicht/Nachsicht*)

R.143 is very quick. This is the well known reaction which already occurred at 70 (*Blume*). It is followed by a longer time and a repetition of the stimulus-word —the only one in the whole series. R.145 is likewise superficial, not even meaningful but only linked in form and sound.

Because they are of no importance I am omitting the subsequent associations.

62. distinguished	noble	1.2
63. tube	sly	0.8 (*Schlauch/schlau*)

The subject explained that at the time of the second of these two reactions she still felt the persistent influence of *distinguished*. The lady had previously been in rather better financial circumstances and occasionally feels this loss.

172. to turn	round	1.4

The cause of this longer time is obscure if *round* does not have the supposed emotional influence mentioned above. The subject has no explanation to offer.

175. trust	me	1.4

Here again we have the fear of the estrangement of her husband—associated with her complex.

190. to bring	something	1.2
191. inn	The Stork	1.0

What *something* represents is clear from the subsequent reaction.

195. mirror	shining	1.4
198. to punish	prison	1.4

Neither of these long reaction-times can be satisfactorily explained. The subject told us that on 195 first the image *glatt* (smooth) occurred to her but this became *glänzend* (shining). It is hard to say why *glatt* should have been suppressed.

Apart from the fact that she had been aware of a slight hesitation, the subject had no explanation for R. 198. Even if we cannot think of a plausible explanation, we may, in the light of previous experience, be fairly sure that some kind of feeling-toned complex is at the root of it. As a later example will show, it does not need to be anything actual, but can be an old reminiscence that has apparently vanished a long time ago.

199. bone	-bed	1.0 (*Knochen / -bett*)

Compare the remarks on 72. The interesting point in this case is that the subject had not the faintest suspicion about the significance of the association.

The following associations should be mentioned:

164. to love	faithful	1.0
167. bill (of exchange)	false	1.0
181. duty	faithful	0.8
187. snake	deceitful	0.8

45 had *false* as reaction in 1.0 seconds, 46 *faithful* in 1.4. These words, for which the subject obviously has a predilection, appear to recur with gradually decreasing reaction-times.[37] It is also interesting that apparently words representing a complex tend to occur automatically in places where the meaning no longer warrants it; this is not the case here, but we have demonstrated it in an earlier investigation.[38]

[606] The analysis of the reactions of this subject have shown that times of over 1.2 seconds, with the exception of a few reactions quoted above, can be attributed to the influence of a feeling-toned complex, for two reasons.

(1) The association through which the complex is constellated has a prolonged reaction-time.

(2) The association immediately following that through which the complex has been constellated has an extended reaction-time owing to the reverberation of the feeling-tone.

[607] Apart from those with longer reaction-times, there are numerous other associations with complex-constellations. In general, reactions with a powerful feeling-tone and a distinct indication of a complex show longer reaction-times. The meaning of the association is grasped with a fair consistency only when a very strong and differentiated feeling-tone, or a very characteristic form of the reaction, brings one complex into consciousness. In the reactions given, this only occurred once, with *stork / to bring*. In all other reactions the feeling-tone, or the special form of the reaction, provided merely pointers to the subsequent identification of the complex.

[608] At the time, only the aspect of the complex appearing in the reaction was available to consciousness. From these facts it becomes evident that consciousness plays only a minor role in the process of association.

[609] All our thinking and acting, the vast bulk of which appears to us to be conscious, actually consist of all those little bits that are finely determined by innumerable impulses completely outside consciousness. To our ego-consciousness the association-process seems to be its own work, subject to its

judgment, free will, and concentration; in reality, however, as our experiment beautifully shows, ego-consciousness is merely the marionette that dances on the stage, moved by a concealed mechanism.[39]

[610] An analysis of this series of tests shows the influence of the complex on association. Although, as people are fond of saying, associations are made at one's own discretion and the subject can say whatever he wishes, nevertheless he does not in fact say what he wishes but is *compelled* to betray precisely what he feels most sure of concealing. The reactions, therefore, are by no means random thoughts but simply symptomatic acts,[40] directed by a psychic factor that can behave like an independent being. The feeling-toned complex, for the time being split off from consciousness, exercises an influence that constantly and successfully competes with the intentions of the ego-complex; in spite of the rejecting and repressing attitude of the ego-complex, it brings about subjective and treacherous reactions and arouses associations the meaning of which is utterly unexpected by the ego-complex. Thus we find a series of intimate secrets divulged in the associations of our subject, and it is not only complexes referring to her actual situation, but the most important complexes, which form the content of her joys and sorrows. At the time of the test we find the most powerful complex to be the psychic equivalent of pregnancy, round which revolve her anxious anticipation and her love for her husband, coupled with slightly jealous fears. This complex is of an erotic nature, and still active; it is therefore understandably in the foreground. Not less than 18 per cent of the associations can safely be related to this.[41] Besides this we find some other complexes, of considerably lower intensity: loss of former prosperity, some deficiencies felt to be disagreeable (singing, swimming, cooking), and finally an erotic complex dating back many years to her youth, which could be shown to be the cause of only a single association. (Unfortunately I have had to leave this one out, out of respect for the subject herself.) The probable mean of this subject was 1.0 second. 30.5 per cent of reactions exceeded this mean, 20.5 per cent took 1.2 seconds. Of these, 32 per cent could clearly be attributed to the influence of a complex. 6 per cent of reactions took 1.4 seconds, 75 per cent of which were certainly conditioned by the complex. 3 per cent were in excess of 1.4 seconds and all of these were certainly due to the influence of a known complex.

[611] *Subject No.* 2: an educated man of middle age. His reaction-type is as objective and superficial as that of Subject No. 1. I shall, therefore, confine

myself to giving only his critical reactions. The subject is a physician and often takes part in our experiments, which he follows with interest.

The probable mean of the series of tests is 1.2 seconds.

1. head	part	1.4
2. green	blue	1.0
3. water	to clean	2.6

The stimulus-word immediately aroused an unpleasant feeling-tone suggesting something sexual, coupled with a sense of inhibition. Immediately after his reaction, the subject clearly recognized that *water* had been understood in the sense of *urine*.

4. to pierce	to strike	1.0
5. angel	pure	1.0
6]. long	large	1.2
7. ship	large	1.0

Here we have a distinct perseveration. With *large*, R.6, there was at first a clearly sexual feeling-tone, followed by the second reaction and immediately afterwards the reason for this was clearly recognized. It concerned a recollection: the subject had heard from us that certain women patients frequently associate sexual implications to the word “long.”

8. to plough	to turn up the soil	1.0
9. wool	sheep	1.2
10. friendly	…, busy	1.2 (*tötig*, *tätig*)
11. table	fish	0.8 (*Tisch/Fisch*)

R.10 is clearly disturbed. We have here a slip of the tongue.[42] The subject immediately corrected himself with *tätig*. At this stage he felt a vaguely unpleasant sensation, somewhat like an inner restlessness, which persisted during the following reaction. Hence the unmotivated rhyme. *Freundlich/tätig* (friendly/busy) is striking, and the subject is unable to explain it. The slip of the tongue that produced *tötig* instead of *tätig* gave the impression that the reaction should really have been *böse* (bad). But even this reaction was incomprehensible to him (for the probable explanation, see below, 86).

15. stem	long	1.2
16. to dance	to steam	1.8 (*tanzen/dampfen*)
17. lake	large	1.2

In R.15 we once again have *long* with its sexual tone and almost simultaneously the reminiscence mentioned above. R.16 is due to similarity of sound and has an abnormally long reaction-time. The sexual tone of R.15 is persisting, with an admixture of irritation, and brings about the repetition of the earlier association *long, large*.

18. ill	poor	1.2
19. pride	bolt	1.6 (*Stolz/Bolz*)

Poor is accompanied by a vague feeling of dislike, but there is no particular image connected with this. *Pride* is felt to be even less pleasant and we had here a feeling of rejection and restraint. The meaningless rhyme and the prolonged time are doubly determined. The subject has financial worries that have been troubling him for some time. He had been accused frequently, particularly in the past, of pride. This reproach, converging with the business of the money, forms a particularly painful contrast. This connection was of course only realized after the reaction was given.

20. to cook	well	1.0
21. ink	to come	1.4 (*Tinte/kommen*)

The association is the phrase “in die Tinte kommen” (to get into hot water); it has an unpleasant tinge and is related by the subject to the money business. There is also an immediate recollection of an erotic complex, dating back several years, which has associations of unpleasure.

24. to swim	well	1.2
25. journey	gay	1.6

Numerous indistinct recollections of travelling with predominantly pleasant associations.

26. blue	lake	1.2
27. bread	daily	2.0

Bread excites a slightly unpleasant feeling—the impression is almost like that of *poor* and there is an accompanying feeling of restriction. Later this is seen to have a clear connection with his financial worries.

28. to threaten	evil	1.4

A very unpleasant tone, connected subsequently with the memory of the erotic complex already mentioned and a feeling of guilt.

29. lamp	shade	1.2
30. rich	poor	1.4

Poor again has the suggestion of unpleasure and again recalls the money business.

31. tree	trunk	1.2
32. to sing	to spring	1.8

Tree again evokes the sexual tone of *long*, for the reasons given above, coupled with irritation; to this is to be related the rhyme and the long reaction-time.

33. sympathy	the poor	1.4
34. yellow	much	1.2 (*gelb/viel*)

The poor again arouses the money-complex, this time with very distinct feeling-tone. *Gelb* (yellow) is at once assimilated as *Geld* (money), in spite of the stimulus-word being correctly understood. The money-complex has forestalled the ego-complex by means of the revealing *much*.

36. to play	ball	1.2
37. salt	dripping	1.4 (*Salz/Schmalz*)

The association *to play/ball*, which in itself is quite innocuous, immediately acquires an erotic feeling-tone, since the word *ball* changed in meaning to *dance*. Here the erotic complex reappeared; hence the rhyme and longer reaction-time in the following association. Needless to say that at the instant of the reaction the trend of thought broadly outlined here was not conscious, but only indicated by fleeting feelings. The awakening of the associated images occurs as a rule afterwards, when the subject’s attention is especially directed to the feeling-tones that appear in their place.

38. new	old	1.2 (*neu/alt*)

The *a* in *alt* was conspicuously prolonged, giving rise to the suggestion that perhaps the reaction should have been *arm* (poor) but it came out as *alt* (old). The money-complex had recently become more acute.

39. morality	immorality	1.8

A slight hesitation—a vague suggestion of guilt in the enunciation of *immorality*. The erotic complex once again.

40. to ride	to drive	1.4

41. wall	place	1.8
42. stupid	clumsy	2.0

The subject can offer no explanation for R.41; he feels as though it should be “no place in the sun.” A somewhat painful tone to R.42 leads straight to the money-complex with the clear recognition that *to drive* is conditioned by the complex, although the feeling-tone peculiar to the complex has emerged only with R.42. The reaction *place* belongs to the money-complex rather than to *wall*. R.42 also makes the erotic complex vibrate slightly.

43. exercise-book	book	1.4
44. to despise	to respect	1.2
45. tooth	money	1.4 (*Zahn/Geld*)

To respect seems to have struck very close to the money-complex because *Zahn* (tooth), in spite of correct interpretation, is assimilated as *zahlen* (to pay), hence *money*. Here again, we have the money-complex forestalling the ego-complex.

46. correct	incorrect	1.2
47. people	poor	1.8

Again the delayed reaction with the money-complex.

60. to hit	marksman	1.2
61. law	not set	4.8

At 61 there is an inexplicable feeling of restraint which for a long time does not permit of any reaction, and then finally a disturbed, meaningless reaction which seems as if it may perhaps be a defensive expression. Later a whole series of painful memories came to mind all of which dealt with actions that, like the erotic complex, did not conform to the laws of morality. The following reaction

62. dear	good	2.0

is also under the influence of these memories of past immorality.

69. part	part of the body	1.8

Here again we have the sexual constellation, as in R.6 and 15.

76. to wash	filth[43]	1.6

A slight feeling of guilt and penitence. Later, the erotic complex. For the coarse mode of expression, see 90.

78. strange	newcomer	2.0

First the feeling that the reaction would be *poor*, but then the reaction *Neuling* (newcomer) predetermined by 38 (*neu/alt* [*arm*]). Of course the reaction followed without any conscious awareness of this constellation. *Strange* has again hit the money-complex. One can see how this complex sends out its *poor* at every opportunity.

79. fortune	misfortune	1.4

is predetermined by the preceding reaction.

80. to tell	mother	1.2
81. propriety	not proper	3.6
82. narrow	narrow-minded	1.8

R.80 followed without any particular feeling-tone. On the other hand *propriety* immediately called up inhibitions with unpleasant feeling, which clearly persisted throughout the following association. Afterwards memories of various scenes from childhood which are clearly constellated by *mother*. It was a matter of a few impressive moments when his mother in rightful anger had maintained that he was not a decent person and never would be. One scene was particularly clear when the subject in his teens had behaved coarsely and indecently towards a lady. This memory led again immediately to the erotic complex and here the subject had something similar to reproach himself with. It must therefore be this complex that is concealed at the root of this long reaction-time, and of the various screen-memories (Freud).

86. false	evil	1.4

Here we have *evil* repeated for the third time. (In the entire series it occurs six times and *good* or *well* five.) *Evil* always brings with it the feeling of guilt that is peculiar to the erotic complex. As you can see, this word, together with *good*, has a similar tendency to increase in frequency, as *poor* does for the money-complex. (*Poor* occurs four times in a manifest and three times in a repressed form.) The first time *evil* appeared was in 10, but at that stage it was obviously repressed, as there are strong inhibitions against the erotic complex in the subject's present emotional life.

89. fire	sea	1.8 (*Brand/Meer*)

The stimulus was correctly understood, but changed immediately into *Brandung* (surf); hence the association of *sea*, with a somewhat longer reaction-time. *Brand* (fire) was therefore assimilated. The previous association does not constellate this assimilation. *Brand*, however, has an unpleasant tone and this is associated in his mind immediately with the meaning of acute alcoholism and, together with the latter, the memory of his having once been in that state, which aroused painful feelings. This time the ego-complex has forestalled the old but still active memory, which has assimilated the stimulus-word in a convenient sense and has thereby drawn a veil over the painful memory, i.e., has hidden it from consciousness. This mechanism (the censor in the Freudian sense)[44] plays a very prominent role in hysteria. It must be emphasized that it is not at all a function of consciousness but an automatic mechanism that regulates what may or may not come into the conscious mind.

90. dirty	filthy (*dreckig*)	1.4

The coarse wording of this reaction is determined by the moral feeling of repugnance that is tied up with the erotic complex.

91. door	to show	1.4

This reaction too, negative and dismissive as it is, is determined by the same feeling.

92. to elect	*Maire* (mayor)	2.2

With *to elect* we meet a new complex. This is a matter of hopes of promotion, of *mehr* (i.e., more) from several points of view. It is at the same time the hope of holding a leading, no longer a subordinate, position. Thus the determination of *Maire* is not purely a matter of sound, but also of sense in a symbolic form. The right reaction would have been *manager*. This word, however, is associated with the secret wish and for that reason is subject to the inhibition that suppresses the wish itself. Thus instead of the correct reaction we have an image associated with it that is outwardly determined by the word *mehr* (more), which itself is characteristic of the momentary mood. This process has great similarities to the hysterical talking at cross purposes of the Ganser syndrome,[45] or perhaps even more to the associating at cross purposes of dementia praecox, in which this kind of metaphor is particularly common. Analogous phenomena occur relatively frequently in everyday life—I mean the word-and-melody automatisms. The following good example was given me by a lady I know. She told me that for some days the name *Taganrog* had been, as it were, on the tip of her tongue but she had not the remotest idea where it came from. I asked her about her emotional experiences and repressed wishes of the recent past. After some hesitation she told me that she very much wanted a housecoat (*Morgenrock*) but that her husband had not shown the desired interest. *Morgenrock : Tag-an-rog*—you can see that the two words are related partially through meaning and partially through sound. The appearance of the Russian name could be attributed to the fact that the lady had met someone from Taganrog at about the same time.[46] Vast numbers of similar combinations can very easily be demonstrated, if one were to take the trouble of getting to the bottom of all the tunes one hums or whistles to oneself or hears from others. A colleague on his hospital rounds caught a fleeting glimpse of a nurse who was allegedly pregnant and caught himself a moment or so later in the act of whistling the tune of: “Es waren zwei Königskinder, die hatten einander so lieb” (There were two royal children, who loved each other so, etc.), although his conscious mind was occupied with something completely different. Another colleague betrayed to me the sad end of a love-affair by a succession of melody automatisms.

One can see from these examples roughly the course taken by thought processes when they lack conscious awareness. Each association occurring in consciousness evokes as it were an echo of similarities and analogies that fades out through all stages of similarity of sound. The best examples are furnished by dreams.

95. mockery	scorn	1.4
99. dog	dead	1.6

This reaction amazed the subject. He could not understand how he could have arrived at this unusual association. The somewhat long time taken suggests a feeling-tone; this is at first described by the subject as indistinct, and then later as sad. The cue *sad* then reminds him of the incident at the root of this feeling. Some twenty years previously he had had to have a dog he was very fond of destroyed. This loss had been *sad* to him for some considerable time.

102. moderate	immoderate	1.6

The longish time of this superficial reaction is explained by its connection with R.89 (*Brand*).

104. to suppose	to believe	2.0

Suppose is a suggestive word as a stimulus and there are few subjects who do not feel affected by it. In this case it hit the erotic complex.

105. pain	scorn	1.2
108. to laugh	to chatter	2.8 (*lachen/schwatzen*)

The *sch* of the reaction *schwatzen* was rather prolonged. First for a moment *schmerzen* (pain) came to mind momentarily though clearly, hence the length of time. *Schmerzen* was at once involuntarily suppressed. The feeling-tone expressed had a tinge of grief. The subject admits having an almost morbid sensitivity to mockery. 95: *mockery/scorn,* 105: *pain/scorn,* and 108: *laugh/pain,* are now closely linked. The determination of *schwatzen* is on the one hand alliteration and on the other semantic relationship: *über Einen schwatzen* (to gossip about someone).

120. to create	to operate	2.0

Here we have the complex of his professional life which produces the lengthened reaction-time.

127. resin	tree	2.0 (*Harz/Baum*)

First, a feeling occurred as if the association was *hart/arm* (hard/poor), in which *arm* was almost spoken out loud. This is a reappearance of the money-complex.

Also the following reaction:

128. to wake	to awaken	1.6

is therefore still very superficial, with relatively long time.

130. bad	evil	0.8
131. briefcase	wood	0.8 (*Mappe/Holz*)

The subject takes *Mappe* in the sense of a briefcase in which he usually fetches (*holen*) money. The reaction *Holz* (wood) is quite meaningless and the subject was amazed at first until he remembered the meaning that he had attributed to *Mappe. Holz* conceals *holen,* which obviously belongs to the repressed money-complex.

148. forget	-fulness	2.0
149. drum	beat	1.2
150. free	-dom	1.2
151. wagon	-barricade	3.0 (*Wagen/-burg*)

148 has a very unpleasant feeling-tone. Nothing particular was reported about 149 and 150, but at 151 there is a strong but inexplicable inhibition. *To forget*

awakens the memory of an event several years ago, when he broke with a faithless friend. 149 is an echo of the song “Der treue Kamerad” (The faithful comrade): “Die Trommel schlug zum Streite/Er ging an meiner Seite, etc.” (The drum beat for the battle, He walked by my side). 150 hints at the break. 151: *wagon* appears to have been assimilated only with difficulty. The compound *Wagen-burg* is strange, but became intelligible through the subject’s remark that the place where he first recognized the friend’s false-heartedness was Augs*burg*. All these data were at the time of the reaction unconscious. The complex betrayed itself at first only by the slightly unpleasant but otherwise indefinable feeling shown in 148. The connection of this series was only established later.

153. impudence	confounded	2.0
154. quick	-ness	0.6

R.153 belongs to the same mood as the reactions given above. (N.B. The analysis of these was undertaken only on completion of the entire series.) This mood is the anger about the insolence of the false friend. This strong feeling-tone seems to have persisted as far as 154.

167. change	of time	1.8

The stimulus-word has again hit the money-complex—hence the long reaction-time.

184. deaf	to fly	2.6 (*taub / fliegen*)

The subject has assimilated *taub* (deaf) as *Taube* (dove) although he did understand the stimulus-word correctly. (He is familiar with the stimulus-words and has experimented with them himself on various occasions.) The reaction-time is very long. *Deaf* hits on a fear-complex of limited range. He suffers from recurrent catarrh of the Eustachian tubes and his hearing in one ear has therefore deteriorated. He connects this fact with the fear, often exaggerated, of becoming totally deaf. *Deaf* thus has too unpleasant a tone and is therefore quickly suppressed.

190. to bring	money	1.2
191. vocabulary[47]	to fetch	2.2

The last reaction is senseless, but can be explained as a perseveration of the money-complex stimulated by *to bring*.

195. mirror	soul	1.8
196. full	filth	1.4

197. understanding	good	1.6
198. to punish	for evil	2.2
200. beautiful	good	1.6

R.195 for some unknown reason is somewhat inhibited. Perhaps “mirror of the soul” already presaged the ethical tone of the following reaction. With *full* it is quite clear: “the soul is full of filth.” This coarse expression again reveals the revulsion already mentioned (90). The following reaction, *good*, is loosely connected with its stimulus-word and is repeated at the next opportunity (200). Each time it represents the erotic complex.

R.198 is clearly influenced by the complex.

[612] In contrast to the case of the previous subject, we have here a whole series of feeling-toned complexes, which are interconnected only slightly or not at all. Whereas with the female subject (No. 1) the sexual complex (pregnancy) with its various branches (fear, jealousy, etc.) is predominant, with the male subject (No. 2) the sexual complexes play a less important part. From personal respect for the subject I cannot give all the reactions. It is easy enough to demonstrate, however:

1. Sexual complexes:

An erotic complex, belonging to the past, now over and done with, which is expressed almost exclusively in ethical feeling-constellations (revulsion, remorse).

An actual erotic complex, expressed merely through erotic feeling-constellations (not reported).

At least three sexually charged ideas, independent of each other.

2. The money-complex.

3. Ambition—with at least four secondary memory-complexes.

4. Personal sensitivity—with at least three secondary memory-complexes.

5. Friendship.

6. Two feeling-toned reminiscences, independent of each other (dead dog, deafness).

[613] Thus we have about ten complexes, independent of each other, that are touched on in the series of experiments. Subject No. 2 is a few years older than No. 1. In the latter case, as was mentioned, 18 per cent of the associations were

to be attributed to the sexual complex, whereas only 4 per cent came under the influence of other emotions. On the other hand, with subject No. 2, 53 per cent of the associations can be related to the influences of complexes. This great number of constellations does not in any way indicate that the analysis was taken further, or that subject No. 2 gave fuller information than No. 1, but it is also to be recognized objectively that subject No. 2 (at least at the time of the experiment) was more emotional than No. 1. We recognize this from the numerous disturbed reactions and the striking assimilations and repressions.[48]

[614] Of the 53 per cent of the associations mentioned, only 10 per cent can be attributed directly to the sexual complex, namely the actual erotic complex, 11.5 per cent to the money-complex, 2.5 per cent to ambition, 4.5 per cent to personal sensitivity, 3 per cent to the broken friendship; to the erotic complex of the past, which is only betrayed by feelings of revulsion and remorse, 9 per cent can be related, and 12.5 per cent are connected to about six smaller, more or less separate emotional complexes. Thus with the male subject the sexual complex as such is very much in the background against the many other influences (10 : 43).

[615] This case shows us even more than the preceding one just how much of the individual personality is contained in the associations. The experiment provides data about a whole series of highly important psychological contents; it gives us as it were a cross-section of the actual personality from a psychological point of view.

[616] *Subject No. 3*: a youngish educated man.[49] I am limiting myself in this case entirely to the critical associations and am reporting on it mainly to show again what in principle emerged in the two preceding cases. The probable mean time for this subject is 1.6 seconds.

1. head	neck	1.2
2. green	mouse	0.8
3. water	green	1.0

What strikes one in this series is the peculiar reaction *mouse* and the perseveration of *green*. *Neck* is a reverberation from the day before the experiment when the subject had seen a film about the death of Marie Antoinette. The subject is not sure where *mouse* comes from, he only has the feeling that it is a slip of the tongue and supposes it should have been *neck (Hals*) or *house*.

4. to pierce	to fence	1.2

5. angel	house	1.6

Here we have, with a long reaction-time, the reaction *house* assumed in 2, and now the memory comes back. The subject's grandfather had often in times past sung the song "Es geht durch alle Lande—ein Engel still" (A silent angel walks through every land, etc.). Just as frequently he would sing: "Mein Häuschen steht im Grünen" (My little house stands in the greenwood, etc.).

A series of feeling-toned images, only some of which are pleasant, are associated with these songs. Hence the perseveration of *green* and the slip of the tongue *mouse*.

13. state	church	1.8

This reaction is somewhat hesitant since *church* represents the sizeable complex of a rather strong religious attitude.

16. to dance	not	1.8

This reaction really is "I cannot dance," to which a very unpleasant feeling is connected, for the subject has experienced a disappointment in love, which a friend who could dance well has been spared.

18. ill	not	1.6

Here again a stimulus-word is felt to apply to himself: he is *not ill* from despair over the unfortunate ending of the romance.

22. angry	friendly	1.8
23. needle	nail	1.2 (*Nadel/Nagel*)

Angry arouses the feeling of jealous animosity that the subject feels towards a certain rival. The sound association that follows is conditioned by the perseveration of this feeling-tone.

30. rich	rather	2.8
31. tree	branches	1.6

R.30 refers to the match that did not materialize, hence the long reaction-time. The next reaction is still somewhat long and has a rather stilted and artificial character; it also seemed to the subject to have a rather ironic tone which holds for the following reactions, too:

32. to sing	beautiful	1.4
33. pity	absolutely not	1.8

by which he means that he does not deserve any pity because everyone forges his own fate.

44. detest	rascals	5.0 (*Kerle*)
47. people	religion	1.6
48. to stink	abominable	1.0
50. unfair	atrocious	1.8

R.44, *rascals*, means the Jews. The lady concerned is Jewish. *People* again arouses the image *Jews* but this is repressed. *Religion* comes in in its place because the religion of his beloved had aroused scruples in the religious-minded subject. The following feeling-toned reactions refer to the complex rather than to the stimulus-words. (Similarly in subject No. 2 a coarse reaction betrayed the affect.)

54. white	snow	1.8

A feeling of “having finished” or “death”; refers to the love-complex.

61. law	absolute	1.4

Here we again have the reaction of R.33 expressing the same feeling: “it is the law, it must be so.”

62. dear	beautiful	1.2
66. tall	fine	1.2

Both reactions have an ironical flavour and relate to the complex.

74. wild	animal	1.8

Wild (dial., “angry”) he applies to himself on account of the complex.

75. family	house	1.0

House seems to represent the complex of all family memories. (Also in *to cook/house*.) Here we have a relatively short reaction-time.

79. luck	game	1.8

Clearly refers to the love-complex.

80. to tell	to talk	1.6 (*erzählen/talk*)

The reaction is in English. We have already seen that French reactions are suspect; this English one too refers to the complex. The subject at first wanted to tell the story of his disappointment to his brother, who lives in America, but then decided against this. Hence the English form.

83. brother	sister 2.0	(*Bruder/sister*)

Again an English form with a long reaction-time! *Brother* has probably subconsciously awakened the image of the earlier reaction. *Sister* comes because his sister at that time was on the point of leaving for a French boarding-school in the same way as his brother had left some time earlier for America. This analogy has condensed itself into *sister*.

88. to kiss	absolutely	1.6

Absolutely is the key-word to the love-complex.

91. door	mouse	1.6

The slip of the tongue of R.2 reappears, probably to mask *house*, which stands for the complex.

92. choose	Kaposi[50]	

Actually the word *caprice* came up momentarily as the reaction, but was immediately suppressed and altered into *Kaposi*. *Caprice* was the choice of the lady in question. *Kaposi* is only an example of similarity in sound and is constellated by a conversation of a few days earlier in which Kaposi was mentioned.

105. pain	kissing	1.0
106. lazy	sow	1.4

The coarser expression of the last reaction is caused by the feeling of anger perseverating from R. 105.

115. intention	kissing	1.8 (*Absicht/küssen*)

Absicht he immediately assimilated as *absolut*, which refers to the complex; he then reacted as if this were the meaning of the stimulus-word.

125. purpose	absolutely none	1.2
126. hot	yes	2.2
134. worthy	daft	2.0
135. danger	glad	1.4

136. high	no, low	2.8
140. to mix	blood	2.0
143. blood	to mix	1.4

These reactions are all sometimes more, sometimes less clearly constellated by the love-complex, and in this naturally the constellating factor was not a clear image, but only a certain not very distinct mood.

144. to let	family	1.6

For a moment *house* loomed up but was repressed and replaced by the somewhat striking reaction *family*. This is association 75, which is again suddenly taken up to mask the word *house*, which represents the complex.

145. caution	intention	2.0 (*Vorsicht/Absicht*)

Here clearly *absolut* came first but was inhibited and masked by *Absicht* through a sound association—perhaps association also contributed.

160. to wish	absolutely not	1.8

[617] I shall not add any more examples; they do not in principle add anything new, only confirm what we have already established with the previous cases.

[618] The love-complex is clearly in the foreground with this subject. At least 52 per cent of the associations can be referred to it with certainty. The family-complex can be demonstrated in 11 per cent of the associations. Now and again there is evidence in 7 per cent of the associations of a complex of ambitious strivings. Numerous individual feeling-toned reminiscences can be demonstrated in 27 per cent of the associations. The general probable mean time in this case is 1.6 seconds. 31 per cent of the reaction-times exceed this mean. 17 per cent amount to 1.8 seconds. Of these 85 per cent are certainly constellated by a complex, whereas in 15 per cent this influence is doubtful or not demonstrated. 4.5 per cent of the associations took 2.0 seconds. 89 per cent of these can with certainty be traced back to the influence of a complex, whereas this influence is uncertain in 11 per cent. 9 per cent of the associations took over 2.0 seconds. All these can be attributed to the influence of a complex.

[619] It is unnecessary to add more examples, for one would constantly have to repeat oneself. As far as our experience goes, the complex-phenomena are the same with all subjects. Only the type of complex, naturally, varies with sex and educational level.[51]

[620] The perseveration of a feeling-tone deserves attention. As is well known, perseveration plays a particularly important part in the pathology of the process of association. Investigations made with normal subjects might be of some help in elucidating the nature of morbid perseveration. In our experiments the perseveration of a feeling-tone occurred so often that we were able to express it statistically to a certain extent. For example, subject No. 2 showed 32 reaction-times of over 1.6 seconds, of which 16 were themselves followed by longer reaction-times. In 10 cases, only the subsequent reaction was prolonged, in 3 the two following, and once in each case the three, four, and five subsequent reaction-times were prolonged. As can be seen from this survey, we quite often observe a discontinuous decrease in the reaction-times. I have seen a quite similar but even clearer discontinuous decrease in some cases of hysteria and dementia praecox, and mostly at points suspect of complex.

[621] To summarize:

(1) From the figures given, it follows that relatively long reaction-times are almost without exception caused by the intervention of a strong feeling-tone.

(2) Strong feeling-tones as a rule belong to extensive and personally important complexes.

(3) The reaction can be an association belonging to a complex of this nature and take its feeling-tone from this complex, though the complex need not be conscious. The *constellation* (Ziehen) of an association is mostly unconscious (or not-conscious); the constellating complex here plays the part of a quasi-independent entity—a “second consciousness.”

(4) The feeling-tone can unconsciously also influence the next reaction, in which several phenomena are to be observed:

(*a*) The reaction influenced by a perseverating feeling-tone has a prolonged reaction-time.

(*b*) The reaction is still an association belonging to the group of images of the preceding complex.

(*c*) The reaction is abnormal in character: it can (*i*) be disturbed through a slip of the tongue or through repetition of the stimulus-word; (*ii*) be abnormally superficial (sound reactions).

(5) The feeling-tones in question are mostly unpleasant.

(6) The characteristics of an unconsciously constellating complex are: long reaction-time, unusual reaction, failures, perseveration, stereotyped repetition of

the stimulus-word (“complex-representative”), translation into foreign language, strong language, quotations, slips of the tongue, assimilation of the stimulus-word (possibly also misunderstanding of the stimulus-word).

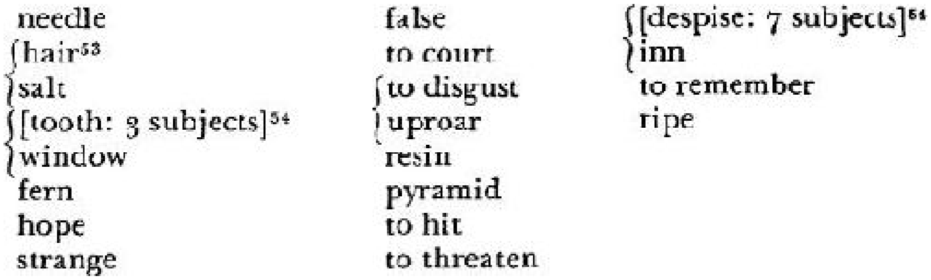
(7) Erotic complexes seem to play a particularly significant part.[52]

H. *The Quantitative Ratio of Prolonged Reaction-times in a Greater Number of Subjects*

A. STIMULUS-WORD AND PROLONGED REACTION-TIME

[622] It would be interesting to learn whether the rules we have discovered in the analyses given above can be applied to a greater number of subjects about whom we have not adequate information. Practical experience teaches us that there are very few people who can pursue their own psychological processes in their subtlest details. Hence a very narrow limit is imposed on subjective analysis. The results given above should, however, make it possible, objectively, to penetrate into the complexes hidden in the associations and at least to demonstrate that rules gained from subjective analysis probably have a general validity. Hence I have investigated, in a comparative manner, the kind of words that are usually followed by prolonged reaction-time. Eleven subjects provided my material; of these, nine were uneducated and two educated.

[623] 1. Five subjects reacted with prolonged times to the following stimulus-words:



needle
hair[53]
salt
[tooth: 3 subjects][54]
window
fern
hope
strange

false
to court
to disgust
uproar
resin
pyramid
to hit
to threaten

[despise: 7 subjects][54]
inn
to remember
ripe

[624] It is not surprising that stimulus-words such as *fern, uproar, resin*, and *pyramid* cause a lengthening in the reaction-time, for they are rather rare words and uneducated people do not have at their disposal ready-made associations to them. But this cannot be said of the words *needle, hair, to hit, ripe*, etc., for these on the contrary are words that occur very frequently in everyday language. The reasons why these words should cause long reaction-times can only be found by means of the above analyses; in most cases they are words that readily arouse emotional associations for they already have in themselves a certain feeling-value, as for example: *hope, false, to hit, to threaten, to remember, ripe*,

etc., for women *hair*, too, should have an emotional value. The words *salt, window, uproar, inn*, have no striking emotional value, but in the original series they follow stimulus-words that evoke feeling; and for this reason, as has many times been shown, come into the orbit of a perseverating feeling-tone. *Hair* and *tooth* can cause long reaction-times, particularly with women, whereas *to disgust* and *to despise* generally stimulate feeling. *Needle* does not in fact follow a stimulus-word arousing feeling; in this case, however, another factor might play a part. This word (*Nadel* in the German original) is pronounced differently in dialect: the vowel *a* is pronounced nearer to an *o* and the ending is transposed into *-dlé*. On the other hand, in the dialect the *a* in the word *Nabel* (navel) is pronounced exactly as in academic German and likewise the ending is unchanged. *Nabel* is the only dialect word that sounds at all like *Nadel* in academic German. For this reason inevitably this word must be evoked in the Swiss-German subject when *Nadel* is called out. As we have seen, it does not necessarily come into consciousness at the time: the inhibition connected with this word can nevertheless influence the association occurring in consciousness. That this is no idle speculation is borne out by the similar case of the word *book*, with which seven out of eleven subjects took prolonged times. *Book (Buck* in German) is pronounced in the dialect as *Buoch*. The dialect word *Buck*, however, means *Bauch* (belly), which is a very unpleasant stimulus-word. In experiments on psychotics it has frequently occurred that *Buch* has been immediately understood as *Bauch* and the corresponding reaction followed.

[625] II. Six out of eleven subjects reacted with prolonged times to the following stimulus-words:

dream
paper
book
frog
nurse (male)
right

damage
to spare
dreadful
gentle
{to surmise: 8 subjects
}of age

impetus
premonition
to stink
to forge
to caress
family

Of age, impetus, and *premonition* can be considered “difficult” words in which the rarity probably prevails over any possible feeling-value.

[626] Since *paper* is a very common word it is difficult to say just what is its capacity to arouse emotion. *Nurse (male*) is effective because it is in constellation with uneducated subjects who are all male or female nurses in our hospital. The meaning of the word *gentle (leise* in German) became clear to me when a South German male nurse reacted with *big (gross)*: he had in fact in the

meantime suppressed the association *Läuse / klein* (lice / small). What matters here is the sound similarity as in the case of *book*. It is striking that so many long reaction-times should occur with the word *frog*. With one exception, the subjects giving these long times were all women. The man who had a long reaction-time could give the reason: *frog* had struck the emotional complex associated with a new-born son. Possibly in the subconscious of a woman, too, the frog's likeness to a small, naked wriggling baby can arouse feeling; so a sexual complex would be touched on which could well be present in every woman, even if only unconsciously.

[627] The feeling-value of the other stimulus-words is clear and requires no further explanation.

[628] III Seven out of eleven subjects reacted to the following stimulus-words with prolonged reaction-times:

freedom
unjust
world
loyalty
consciousness

to disgust
to despise
to pay attention
to kiss

Only *consciousness* could be rated as "difficult." The stimulus-words *freedom, unjust*, and *to pay attention* presumably produce long reaction-times in the nursing staff, which can easily be understood. *World* may well have prolonged times so frequently because it is placed between two words that arouse emotions.

[629] IV. Eight to ten out of eleven subjects had long reaction-times to the following stimulus-words:

heart
violence
wonder

to surmise
to kiss: 7 subjects
natural: 9 "

It is not so much the relative rarity of the word *to surmise* that is important, but its capacity to arouse complexes. *Miracle* often seems to excite religious complexes associated with inhibitions. *Natural* is influenced by the immediately preceding erotic-sexual stimulant *to kiss* and is therefore very embarrassing for both sexes. *Violence* attracts the maximum of prolonged reaction-times. This is perhaps mainly due to the fact that all the subjects are closely connected with the mental hospital.

[630] From this account we can see that the difficulty or rarity of a stimulus-word can certainly influence the reaction-time; but in the vast majority of cases the stimulus-words that produce long reaction-times are characterized by a high feeling-value. Thus the principal cause of prolonged reaction-times. This objective statistical examination shows the principal cause of prolonged reaction-times to be the emotional effect of the stimulus-word.

[631] I have tried to estimate roughly the quantitative values for the four series given above, and have compiled them in the following summary:

Out of 200 stimulus-words, 48 aroused prolonged reaction-times in 5 or more out of 11 subjects.

17 stimulus-words produced prolonged reaction-times in 5 subjects. Of these 76% referred to affective images.

17 stimulus-words produced prolonged reaction-times in 6 subjects. Of these 76% referred to affective images.

9 stimulus-words produced prolonged reaction-times in 7 subjects. Of these 89% referred to affective images.

5 stimulus-words produced prolonged reaction-times in 8 to 10 subjects. Of these 90% referred to affective images.

[632] On the average, therefore, approximately 83 per cent of the stimulus-words producing prolonged reaction-times have affective value, whereas only about 17 per cent have a delaying influence through their intrinsic difficulty. Of the stimulus-words arousing affects, at least 28 per cent have a mainly erotic-sexual affective value.

B. INCIDENCE OF PROLONGED REACTION-TIMES WITH INDIVIDUAL SUBJECTS

[633] It follows from the explanations given above that emotional processes are of the greatest significance in the origin or formation of abnormally long reaction-times. As we know from everyday experience, it is in the sphere of the emotions that the greatest individual differences exist. For this reason, it should be worthwhile investigating what is the numerical proportion of abnormally long times with the different subjects. For this investigation, I used the material given by twenty-six subjects. (Uneducated: seven women and seven men. Educated: six women and six men. Thus a total of over 4,000 individual data.)

[634] As already mentioned, all those reaction-times that exceeded the individual probable mean times were considered to be prolonged. True, we came upon a

series of reactions showing neither a particularly long duration nor obvious complex-influence. On the other hand, if we raise the upper individual limit for normal times, we are thrown on to the arithmetical mean in which the prolonged times are taken into account. This limit is then individually far too high, for which reason no characteristic figures can be obtained in this way. I therefore decided to select the individual probable mean as the upper limit, first, because the abnormally long times are not taken into account in this (the probable mean is as a rule lower than the arithmetical mean) and, secondly, because (according to the analysis of subject No. 1) of those times exceeding the probable mean by only 0.2 seconds, almost a third are clearly influenced by feeling-toned complexes, whereas all the very long times depend entirely on the effect of complexes. In this way we encounter almost all the prolonged reaction-times produced by affects. As is clear from several examples, there is a certain proportion between the intensity of the affect and the length of the reaction-time. Hence one can deduce, *cum grano salis*, very intensive affects from very long reaction-times. By means of the arithmetical mean the prolonged reaction-times are taken abundantly into account in a calculation of averages. For the four groups mentioned I am giving the figures for the probable and arithmetical means, the percentages of prolonged reaction-times, and the difference between the two means.

		Probable Mean	Arithmetical Mean	Difference	% of Prolonged Reaction-times
Uneducated	Women	2.2	2.9	0.7	49.2
	Men	1.8	2.4	0.6	40.9
Educated	Women	1.7	2.2	0.5	42.4
	Men	1.3	1.7	0.4	41.8

[635] The four columns in this table all say approximately the same thing in different forms, namely that the uneducated women, as well as having the highest probable mean, also have the greatest number of prolonged reaction-times. The differences between probable and arithmetical mean times are most instructive: the group of educated men has a smaller difference than the other three groups. This figure states that the prolonged reaction-times of educated men are on average shorter than those of the other groups, that consequently the emotional inhibitions in all the other subjects—for this is the main point, not the difference in educational levels—even if they do not always occur more frequently, are still more fundamental and abundant than those of the educated men. From this I see that the experimenter, who is in every respect on the same level as the group of educated men, as far as the other groups are concerned is

of the opposite sex or a superior or both. This seems to me sufficient reason for the prevalence of emotional inhibitions in the other subjects.

[636] In stating the influences of the emotions on the length of reaction-times, I have ventured into a sphere so complicated, and therefore so subject to great individual variations, that there is no point in giving the individual figures on which the above table is based. Only untenable hypotheses could be based on the differences.

GENERAL RECAPITULATION

[637] A. In time-measurements, using a stop-watch, made with both educated and uneducated subjects, the average reaction-time came out at 1.8 seconds.

B. The times of male subjects (1.6 seconds) are on average shorter than those of female subjects (2.9 seconds).

C. Similarly, the times of educated subjects (1.5 seconds) are, on average, shorter than those of the uneducated (2.0 seconds).

D. The quality of the stimulus-word exerts a certain influence on the reaction-time. The average shortest times follow concrete nouns (1.67 seconds), the longest follow abstract nouns and verbs (1.95 and 1.90 seconds). Educated men form an exception to this rule in that with them it is usually the concrete nouns that are followed by the longest times.

E. The quality of the reaction also seems to have a certain influence on the length of the reaction-time. The longest times occur with abstract nouns (1.98 seconds), the shortest with adjectives and verbs (1.65 and 1.66 seconds). Concrete nouns (1.81 seconds) are in the middle. Educated men here again are the exception in that their longest time occurs with concrete nouns.

F. The quality of the association has a distinct influence on the reaction-time. Internal associations command a longer reaction-time than external ones. Sound reactions generally show relatively long times because they are abnormal and owe their appearance to certain disturbances occasioned by inner distractions.

G. Those reaction-times that exceed the probable mean are for the most part caused by the eruption of intense emotions associated with individually important complex-images. The subject is mostly unaware of the reason for the prolonged reaction-time. Hence, too, long reaction-times can serve as a means of uncovering emotionally charged complexes, both conscious and unconscious. (Important in hysteria!)

H. Prolonged reaction-times tend to follow certain stimulus-words. About 83 per cent of these are mainly characterized by their affective value, whereas only about 17 per cent cause prolonged reaction-times on account of their difficulty or rarity.

[638] Very frequently the dying away of the feeling-tone is shown and it extends to the subsequent reactions which are thereby disturbed (perseveration).

EXPERIMENTAL OBSERVATIONS ON THE FACULTY OF MEMORY[1]

[639] We have often observed in our association experiments with hysterical patients that the patient would not react for a long time to stimulus-words that were obviously related to his complex, and then would suddenly ask, “What was the word you said?” Closer interrogation revealed that the patient had forgotten the word of which he had just been reminded. We immediately recognized that this striking disturbance of memory was identical with the type of *forgetting* described by Freud, i.e., the “not wanting to remember” unpleasant impressions. The phenomenon that we observed is a particular case of a general tendency to repress and then forget the unpleasant image. (Cf. Freud’s papers.[2])

[640] It is to the credit of Freud, and partly also of Breuer—as is probably well known—that they have amply demonstrated this fact (forgetting equated with repression) in hysterical patients. The validity of this can be doubted only by someone who has not himself tested Freudian psychoanalysis. In more recent works[3] Freud has demonstrated that the same mechanisms of repression are at work in the normal dream and in trivial incidents of everyday life (parapraxes in speaking, reading, etc.). In our experimental investigations we have also succeeded in demonstrating the repressed complex in such associations as are produced by calling out a stimulus-word. The laying bare of a repressed complex is of immense practical importance, e.g., in hysteria. Every hysterical patient has a repressed complex of causal significance. It is therefore essential for treatment that the complex be identified, unless one wants to forego such important psychotherapeutic aids. As Freud has shown, however, the inhibitions repressing the complex are so strong that the images concerned are very often split off from consciousness. It was to overcome this barrier that Freud invented his ingenious method of *free association*. This method is, however, extremely time-consuming and its use presupposes certain qualities in both the patient and the doctor. The same inhibitions are betrayed in our own method of association. A

tabulation of the stimulus-words that have brought up inhibitions shows quite clearly into which category the repressed complex may fall, and from this one can obtain valuable pointers to supplementary questions. To get a clearer idea of the type of complex one can then intersperse additional pertinent stimulus-words. The art of the method, which is never easy to use, lies in distinguishing the reactions connected with a complex from the irrelevant ones. I have therefore compiled a series of so-called *complex-characteristics*.[4] In principle the complex-characteristics are the same for normal and pathological associations. Furthermore, to lay bare the complex is of far-reaching significance in applying our experiments to the field of criminal psychology. Hans Gross and his pupils have shown this, stimulated by our experiments.[5] The complex in this case is the fact of a crime: the stimulus-words are the designations of things associated with the mental picture of the crime.

[641] The observations mentioned in our first paragraph became the point of departure for a new method that points to those associations attributable to complexes. The *reproduction method*, as I should like to call it, can be described as follows: After completing an association test (usually one hundred words), we try to find out whether the subject remembers how he reacted to individual stimulus-words. We simply repeat the experiment, always allowing the patient enough time to recall his previous reactions. In this reproduction method certain regular characteristics come to light, which I should now like to outline briefly. In these experiments my leading idea was to find out whether failures of memory were accidental or whether a system behind them could be revealed. I have carried out this experiment on mentally healthy people and on patients, and have, at least in principle, always found the same phenomena. (Organic disturbances of memory are of course excepted.) As this article is only concerned with establishing and describing this phenomenon, I have selected as examples two pathological cases in which the phenomenon in question is quite pronounced.

[642]

CASE NO. I

A 32-year-old professional musician who was undergoing psychoanalytical treatment because of vague anxiety-states and a compulsive fear of not being able to give solo performances. Two years previously he had become engaged, but the engagement soon broke up owing to moodiness and quarrelling. The young woman was of an implacable, quarrelsome, and jealous nature. This led to violent rows and finally to the breaking off of the engagement when the patient made the mistake of writing picture postcards to another girl. During the nights following these quarrels the patient could not sleep, and it was then that the first nervous symptoms appeared. About a year previously he had had a secret affair with a lady of a rich and distinguished family, but this had soon been broken off. In January of that year the patient became engaged to a rather unintelligent girl who was, however, already three months pregnant by another man, which the patient did not then know. The numerous excitements brought on by these circumstances aggravated his nervous condition to such an extent that he had to seek medical advice. It should also be mentioned that he had led a very dissolute life between the ages of 18 and 25, as a result of which his physical strength had allegedly been greatly impaired.

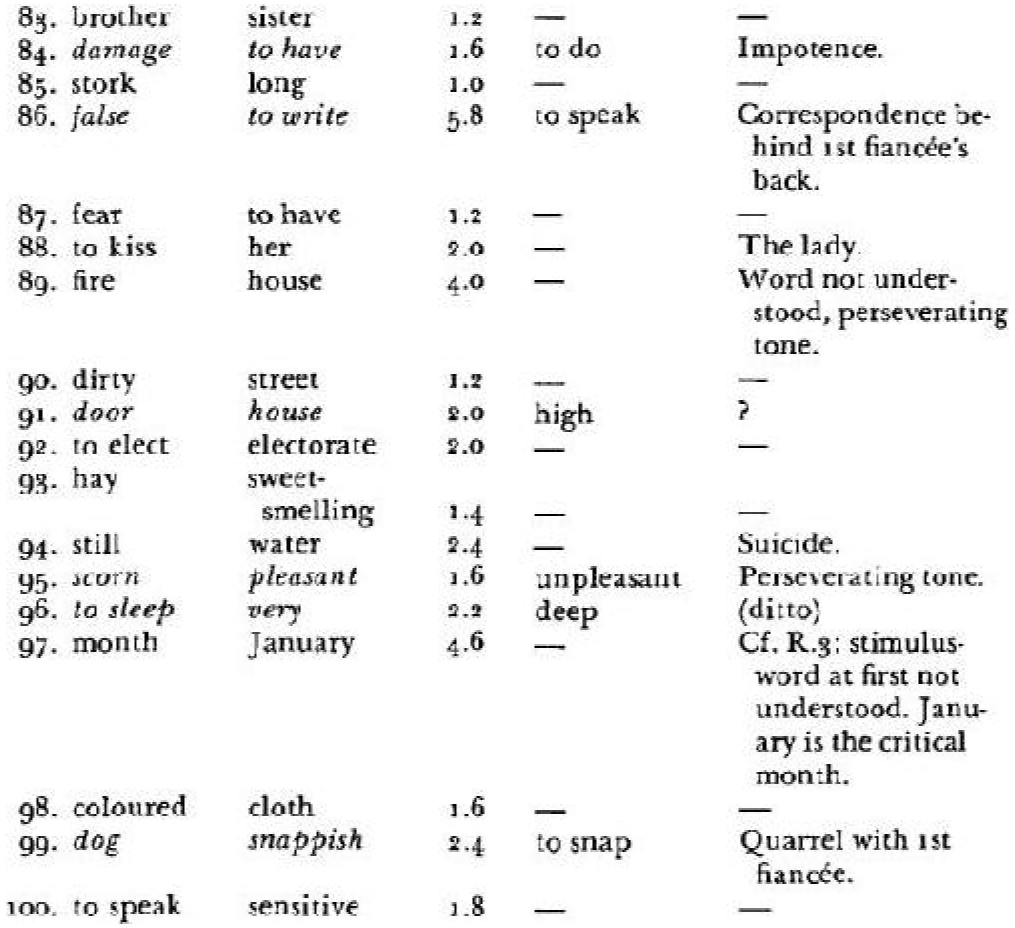
Association and Reproduction Test

[643] The results of the two tests are set side by side. Those associations that were either not reproduced or wrongly reproduced are shown in italic type.[6]

Stimulus-word	Re-action	Re-action-time (secs.)	Repro-duction	Remarks
1. *head*	*empty*	3.2	to see	Complex underlying the illness.
2. *green*	*lawn*	2.2	colour, tree	Probably perseverating feeling-tone.
3. *water*	*to drown*	2.2	deep	The patient had had thoughts of suicide as a result of his illness.
4. *to stab*	*dead*	1.8	unpleasant	—
5. angel	beautiful	8.0		Here the feeling-tone of the previous reaction has probably perseverated. Word not at first understood. Erotic reminiscences easily aroused by this word.
6. long	table	2.8	—	—
7. *ship*	*crew*	9.0	to travel, to drown	Suicide by drowning.
8. to plough	peasant	2.0	—	—
9. wool	sheep	2.0	—	—
10. friendly	very	2.8	—	Affair with the lady.
11. desk	high	3.6	—	Prolonged reaction-time due to perseverating feeling-tone.
12. *to ask*	*difficult*	3.2	to put	Same complex.
13. state	beautiful	2.4	—	—
14. obstinate	very	2.0	—	1st fiancée.
15. stalk	green	2.2	—	—
16. to dance	good	2.2	—	—
17. lake	stormy	2.0	—	—
18. ill	unpleasant	8.8	—	Illness.
19. conceit	very	2.8	—	Relations with the lady.
20. to cook	good	2.0	—	—
21. ink	black	1.8	—	—
22. wicked	very	4.8	—	1st fiancée.
23. pin	prick	1.4	—	—
24. *to swim*	*not*	2.8	good	Suicide.
25. *journey*	*difficult*	2.4	long	Perseverating feeling-tone.
26. blue	colour	2.0	—	—

27. bread	to taste	2.8	—	—
28. to threaten	me	10.4	—	Fear of the future: suicide.
29. *lamp*	*good*	2.2	to burn	Perseverating feeling-tone.
30. rich	pleasant	3.4	—	The lady.
31. *tree*	*green*	2.0	high	Perseverating feeling-tone.
32. *to sing*	*beautiful*	1.4	good	(ditto)
33. *sympathy*	*pleasant*	4.6	to have	Ostensibly the illness-complex, but probably something else as well which is not divulged.
34. *yellow*	*material*	5.4	colour	Not at first understood.
35. mountain	high	1.2	—	—
36. to play	children	2.4	—	—
37. salt	bitter	1.8	—	—
38. *new*	*material*	2.4	dress	?
39. *habits*	*good*	3.0	bad	Early life: adulterous relationship with the lady.
40. to ride	pleasant	3.5	—	—
41. wall	white	2.2	—	—
42. *stupid*	*cattle*	4.8	very	2nd fiancée.
43. *notebook*	*blue*	2.2	to write	Perseverating feeling-tone.
44. *to despise*	*him*	3.4	me	Early life: erotic complexes.
45. *tooth*	*sharp*	2.2	long	Perseverating feeling-tone.
46. correct	to write	3.8	—	Correspondence behind 1st fiancée's back.
47. people	Swiss	2.4	—	—
48. to stink	dung	2.0	—	—
49. *book*	*beautiful*	3.6	good	Perhaps not at first understood. Otherwise?
50. *unjust*	*judge*	2.0	very	The reaction *very* might indicate a connection with one of the erotic complexes.

52. to separate	acid (noun)	6.0	—	Not at first understood. Relationship with the lady.
53. hunger	pang	2.0	—	—
54. white	lamb	2.2	—	—
55. *cattle*	*to slaughter*	4.4	to kill	Memories of quarrels with 1st fiancée.
56. to pay attention	very	2.0	—	Perseverating tone.
57. pencil	long	2.0	—	—
58. sultry	weather	4.8	—	—
59. plum	blue	1.8	—	—
60. *to hit*	*target*	2.0	marksman	Rendezvous with the lady.
61. law	to despise	2.6	—	The lady is married.
62. dear	she	2.6	—	The lady.
63. glass	transparent	2.0	—	—
64. *to quarrel*	*unpleasant*	2.2	violent	1st fiancée.
65. goat	pasture	3.8	—	Perseverating tone. Stimulus-word was repeated by the patient.
66. *big*	*man*	2.4	child	?
67. potato	to eat	1.8	—	—
68. *to paint*	*wall*	3.2	beautiful	?
69. *part*	*whole*	3.0	?	Suggestion of "sexual parts."
70. *old*	*coin*	7.4	man	As a result of previous word the fear of impotence is aroused.
71. flower	smells	1.6	—	—
72. *to fight*	*stick*	2.0	violent	Quarrel with 1st fiancée.
73. *box*	*to put in*	3.4	?	Perseverating tone.
74. wild	horse	1.6	—	—
75. family	to have	2.6	—	2nd fiancée.
76. to wash	face	1.8	—	—
77. *cow*	*to slaughter*	2.6	to kill	Memories of rows with 1st fiancée.
78. strange	to me	2.0	—	1st fiancée.
79. luck	to have	1.6	—	—
80. to tell	story	1.6	—	—
81. *poise*	*good*	2.0	habit	Early life: the lady.
82. narrow	boot	1.8	—	—



83. brother	sister	1.2	—	—
84. *damage*	*to have*	1.6	to do	Impotence.
85. stork	long	1.0	—	—
86. *false*	*to write*	5.8	to speak	Correspondence behind 1st fiancée's back.
87. fear	to have	1.2	—	—
88. to kiss	her	2.0	—	The lady.
89. fire	house	4.0	—	Word not understood, perseverating tone.
90. dirty	street	1.2	—	—
91. *door*	*house*	2.0	high	?
92. to elect	electorate	2.0	—	—
93. hay	sweet-smelling	1.4	—	—
94. still	water	2.4	—	Suicide.
95. *scorn*	*pleasant*	1.6	unpleasant	Perseverating tone.
96. *to sleep*	*very*	2.2	deep	(ditto)
97. month	January	4.6	—	Cf. R.3: stimulus-word at first not understood. January is the critical month.
98. coloured	cloth	1.6	—	—
99. *dog*	*snappish*	2.4	to snap	Quarrel with 1st fiancée.
100. to speak	sensitive	1.8	—	—

[644] In these associations several clearly feeling-toned complexes are evoked. Their symptoms are mainly a delayed reaction and its influence on the following reactions. I will not proceed further with this analysis as it might lead too far.[7]

[645] The remarks given with the reactions should enable the reader to get his bearings. Those points where the analysis showed an association constellated by a complex have been noted. If we now look over the whole experiment we can see that, with very few exceptions, the incorrect reproductions to the repeated stimulus-words are those that are directly constellated by a feeling-toned complex or those that immediately follow a critical one, and therefore fall within the area of the perseverating feeling-tone. In many places the perseveration can be quite easily recognized by the prolonged reaction-time or by the form and content of the reaction. Out of 38 incorrect reproductions there are only five in which analysis could not demonstrate any kind of complex-

constellation. Nevertheless, the prolonged reaction-times usually found in such places indicate a feeling-tone.

[646] Analysis is exceptionally difficult and time-consuming in the case of half-educated and uneducated people; in fact, it often proves almost impossible to reach any depth because of lack of co-operation. Also, with patients from an out-patients' clinic, you may easily meet people who have every reason to keep their secrets. Apart from these exceptions, which need not be considered, it becomes quite clear that the forgetting does not apply to the irrelevant reactions, but to the significant complex-reactions. Should this be generally confirmed, we should have found a method, in this reproduction process, of objectively revealing complexes from the reactions. But this method can also be theoretically valuable in that it shows us a way to investigate the much discussed connection between feeling-tone and memory.

[647] Before we go further into these questions, I should like to refer to a second case.

[648]

CASE NO. II

An educated young man, 22 years old, excitable and sensitive, sanguine, morally unsound, not particularly intelligent. He is well known to the writer and has also given sufficient information about the complexes broached by the associations.

Complex I: The patient is very excitable and extraordinarily sensitive. This characteristic brings him into frequent conflict with his environment. One of these conflicts has led him to a mental hospital. The patient had a good friend who once made a joke of sketching him with ass's ears, and produced this caricature in the presence of ladies. The patient took him to task about this, but the perpetrator denied having done it, whereupon the patient slapped his face and challenged him to a duel with sabres.

His relationship with his family is strained.

Complex II: Numerous love-affairs. The patient had been given a diamond pin by one amorous lady, which he wore in his tie, and had recently lost a stone from this, which annoyed him a great deal. One of these relationships is with a Greek woman. In the year he has just completed in the cavalry he led a wild and dissolute life.

Complex III: The patient recently wanted to become engaged to a woman of means, but it came to nothing.

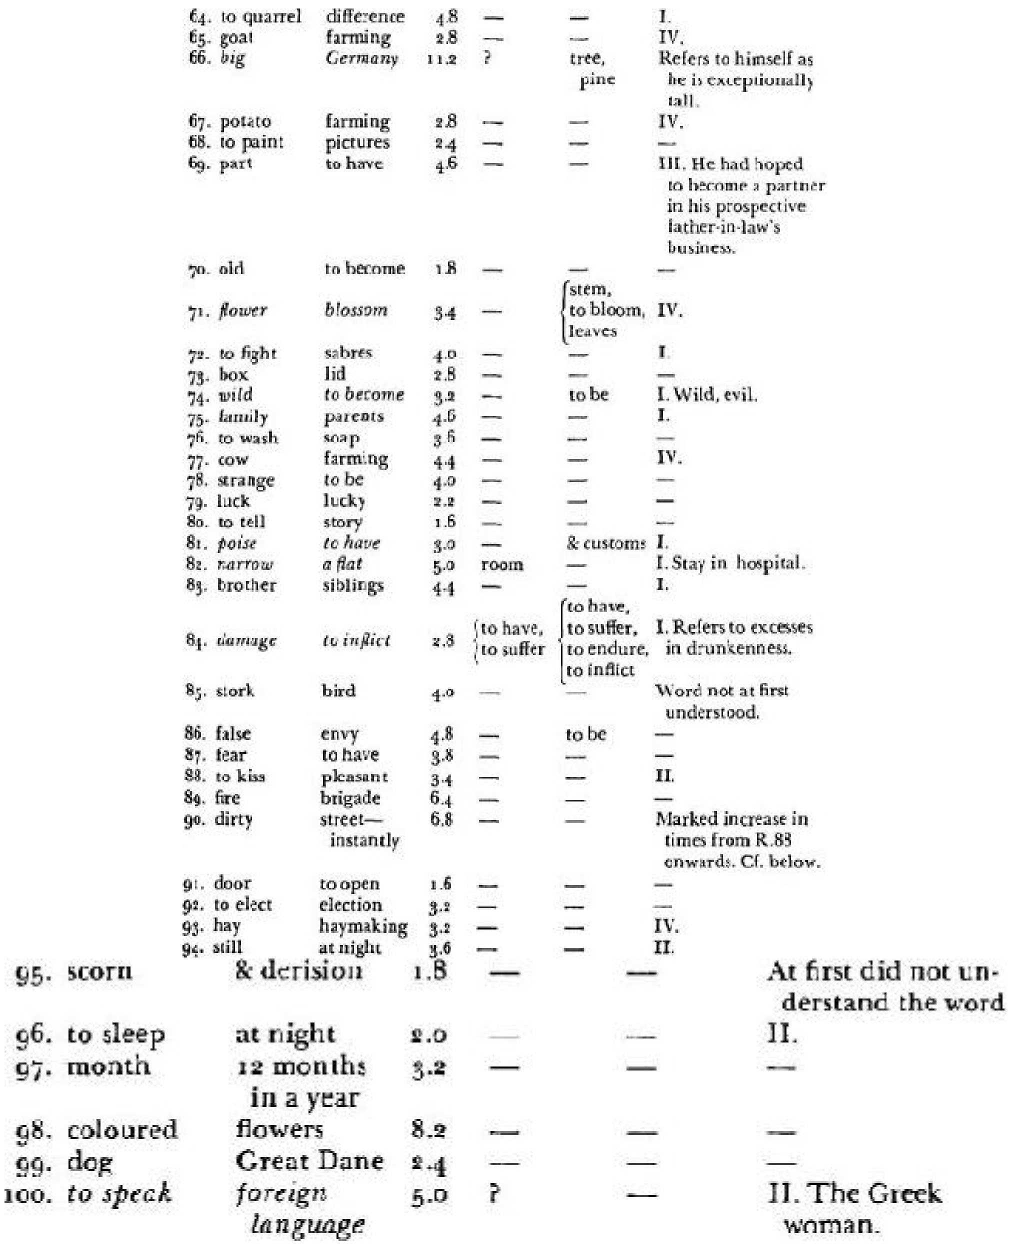
Complex IV; The patient has decided to study agriculture, which seems to keep him occupied for the time being, and he is also enthusiastic about rowing and other sports.

[649] I am giving full details of the associations in this case. The method of analysis is the same as that I have already demonstrated in the work on the reaction-times. I have marked with the appropriate number all the places where the analysis certainly or in all probability shows a complex. Those associations to which the reactions were either not remembered or wrongly remembered in the reproduction test are shown in the table, as on the previous occasion.

	Stimulus-word	Re-action	Re-action-time (secs.)	1st Repro-duction	2nd Repro-duction	Remarks
1.	*head*	*hat*	2.8	—	cover	Stupidity complex (ass's ears) and the supposition, owing to stay in mental hospital, that he is mentally ill.
2.	green	colour	1.4	—	—	—
3.	*water*	*to row*	2.6	?	—	IV.
4.	to stab	spear	2.8	—	—	I. Sabre duel.
5.	angel	heaven	1.8	—	—	—
6.	long	—	—	—	—	I. Not understood, reaction omitted.
7.	ship	-building	1.0	—	—	—
8.	to plough	field	2.2	—	—	IV.
9.	wool	sheep	1.2	—	—	
10.	friendly	Mr. Z.	2.4	—	—	Acquaintance at the hospital.
11.	desk	bank	2.2	—	—	—
12.	*to ask*	*answer*	3.6	?	—	III.
13.	*state*	*Switzerland*	3.8	—	institution	Preceding R. 12 refers to complex III. Owing to the perseverating feeling-tone the reproduction is disturbed.

14. obstinate	wench	4.8	—	—	"The Obstinate Wench," popular song. The stimulus-word *to ask* has touched complex III. How much the feeling-tone reverberates can be gathered from the way the reaction-times increase and from the content of R.14.
15. stalk	flower	1.8	—	—	—
16. to dance	ladies	3.8	—	—	II.
17. lake	Zurich	2.0	—	—	IV.
18. *ill*	*medicine*	4.2	—	to be	I. Complex of hospitalization, observation of his mental state.
19. conceit	Mr. S.	1.8	—	—	I. Acquaintance in the hospital.
20. to cook	kitchen	2.0	—	—	—
21. ink	to write	1.6	—	—	—
22. *wicked*	*Mr. C.*	3.0	to be	—	I.
23. *pin*	*tie*	3.2	cravat	tie-pin	II.
24. to swim	water	2.0	—	—	IV.
25. journey	adventure	3.8	—	—	II.
26. blue	colour	2.4	—	—	—
27. bread	corn	2.8	—	—	IV.
28. *to threaten*	*angry*	3.0	—	someone	I. Duel complex.
29. lamp	light	2.0	—	—	—
30. *rich*	*money*	3.4	—	to be	III.
31. *tree*	*leaves*	3.0	leaf	—	—
32. to sing	music	2.8	—	—	Here the critical reaction is obviously *rich/money*, after which the reaction-times decrease in proportion. The reaction after the critical one is uncertain
33. sympathy	to have	2.6	—	—	—

34. yellow	colour	2.8	—	—	—
35. *mountain*	*climbing*	1.8	—	tour	—
36. to play	tennis	3.0	—	—	IV.
37. salt	sea	4.2	—	—	—
38. new	Greek	6.2	—	—	II.
39. habits	& customs	2.2	—	—	—
40. to ride	horse	1.8	—	—	II.
41. wall	papered	3.4	—	—	—
42. *stupid*	*Mr. B.*	6.4	to be	—	I. Similar to R.22, same complex.
43. notebook	to write	2.2	—	—	—
44. to despise	Mr. H.	2.8	—	—	I. Acquaintance in the hospital. With this man the patient had had a similar experience to that given in complex I.
45. tooth	to pull	2.4	—	—	—
46. *correct*	*answer*	8.0	right and proper	—	I. Connected with the denial in complex I.
47. people	race	2.0	—	—	—
48. to stink	carbolic	3.6	—	—	I. The hospital.
49. book	to read	1.6	—	—	—
50. unjust	Russia	3.0	—	—	—
51. frog	leg	1.6	—	—	—
52. *to separate*	*marriage*	6.0	?	—	III.
53. hunger	to eat	4.0	—	—	—
54. white	colour	3.4	—	—	—
55. cattle	cattle-breeding	2.6	—	—	IV. Here again the timing shows a regular decrease after the critical reaction.
56. *to pay attention*	*lecture*	6.2	—	question	IV.
57. pencil	to write	4.2	—	—	—
58. sultry	sky	7.6	—	—	I. Stay in hospital.
59. plum	stone-fruit	3.0	—	—	IV.
60. to hit	to shoot	2.6	—	—	I.
61. *law*	*state institutions*	6.2	?	—	I.
62. dear	beloved	7.4	—	—	II or III.
63. glass	water	2.2	—	—	—



64. to quarrel	difference	4.8	—	—	I.
65. goat	farming	2.8	—	—	IV.
66. *big*	*Germany*	11.2	?	tree, pine	Refers to himself as he is exceptionally tall.
67. potato	farming	2.8	—	—	IV.
68. to paint	pictures	2.4	—	—	—
69. part	to have	4.6	—	—	III. He had hoped to become a partner in his prospective father-in-law's business.
70. old	to become	1.8	—	—	—
71. *flower*	*blossom*	3.4	—	stem, to bloom, leaves	IV.
72. to fight	sabres	4.0	—	—	I.
73. box	lid	2.8	—	—	—
74. *wild*	*to become*	3.2	—	to be	I. Wild, evil.
75. family	parents	4.6	—	—	I.
76. to wash	soap	3.6	—	—	—
77. cow	farming	4.4	—	—	IV.
78. strange	to be	4.0	—	—	—
79. luck	lucky	2.2	—	—	—
80. to tell	story	1.6	—	—	—
81. *poise*	*to have*	3.0	—	& customs	I.
82. *narrow*	*a flat*	5.0	room	—	I. Stay in hospital.
83. brother	siblings	4.4	—	—	I.
84. *damage*	*to inflict*	2.8	to have, to suffer	to have, to suffer, to endure, to inflict	I. Refers to excesses in drunkenness.
85. stork	bird	4.0	—	—	Word not at first understood.
86. false	envy	4.8	—	to be	—
87. fear	to have	3.8	—	—	—
88. to kiss	pleasant	3.4	—	—	II.
89. fire	brigade	6.4	—	—	—
90. dirty	street—instantly	6.8	—	—	Marked increase in times from R.88 onwards. Cf. below.
91. door	to open	1.6	—	—	—
92. to elect	election	3.2	—	—	—
93. hay	haymaking	3.2	—	—	IV.
94. still	at night	3.6	—	—	II.
95. scorn	& derision	1.8	—	—	At first did not understand the word
96. to sleep	at night	2.0	—	—	II.
97. month	12 months in a year	3.2	—	—	—
98. coloured	flowers	8.2	—	—	—
99. dog	Great Dane	2.4	—	—	—
100. *to speak*	*foreign language*	5.0	?	—	II. The Greek woman.

Note to test: Reactions 94–98 are influenced by a complex that requires some elucidation. These reactions show various intense *complex-characteristics*. Obviously the complex is hidden by the words *at night*. From the first reproduction onwards, there is a marked increase in the reaction-time. I suggested to the patient that this might be due to a more recent love affair, but he did not admit it. There is a similar increase in the time taken after 88, *to kiss/pleasant*, and it is difficult to understand why 56, *to pay attention/lecture*, should take as long as 6.2 seconds. Complex-characteristics in reactions to words such as *to kiss, to sleep,* *still, to pay attention*, gave rise to the suspicion that the patient had begun an affair behind our back.

On the day following these tests we intercepted a letter addressed to the patient. This was from a girl whom he had met when he was allowed to go out on parole, and suggested how they could keep their relationship secret and how they could arrange a rendezvous.

[650] In this series of associations there are obvious complexes expressed in the usual way. Out of one hundred reactions there are only 13 in which memory failed. When we now examine where these 13 unrepeated reactions occur, we see that 12 of them are found at points constellated by a complex;[7a] one follows immediately on a complex-reaction. We may therefore suppose that the disturbance of memory is connected with the complex, or with its feeling-tone. As I have shown earlier,[8] strong emotions, especially feelings of unpleasure, are expressed in abnormally long reaction-times.

[651] The arithmetical mean time of all correctly repeated reactions is 3.0 seconds. The mean of those not repeated is 5.0 seconds. Thus the times taken for those reactions not repeated are significantly longer than those of the others, which gives us an objective confirmation of our supposition that there is a connection between the disturbance of memory and the strong feeling-tone of the reaction.

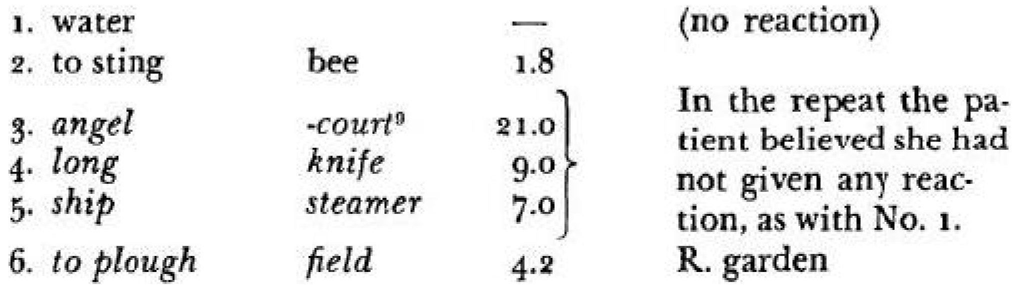
[652] The first reproduction test followed immediately after the initial test of one hundred reactions. I had the test repeated again on the following day, and the results are shown in the column headed “2nd Reproduction.”

[653] Of the hundred reactions, 14 were incorrectly reproduced on the second occasion. (The second reproduction was assumed to be correct if it was the same as the first reproduction, when the initial reaction had been incorrectly remembered.)

[654] Eleven of the fourteen incorrect reproductions concern reactions that had been correctly reproduced the first time but that, because of their content or the length of time taken, appeared to suggest the presence of a complex. Only three were wrongly remembered on the second reproduction. We can thus see that the amnestic blockages have

developed further in the same direction as in the first reproduction test, and give rise to a series of reactions that also belong to the complexes. For practical purposes it would seem to be advisable to leave some time between the first test and the reproduction tests.

[655] In my experience the amnestic blockages occur just as frequently with critical reactions as with those immediately following. These two cases represent the usual behaviour. But there are even more island-like amnesias, particularly, as it seems, in hysteria, where the feeling-tones are of great intensity and can extend over many subsequent reactions. Thus, I recently found in the case of a 23-year-old hysterical woman, who had only 13 per cent incorrect reproductions, the following interesting chain of reactions:



1. water		—	(no reaction)
2. to sting	bee	1.8	
3. *angel*	*-court*[9]	21.0	In the repeat the patient believed she had not given any reaction, as with No. 1.
4. *long*	*knife*	9.0	
5. *ship*	*steamer*	7.0	
6. *to plough*	*field*	4.2	R. garden

[656] The stimulus-word *water* had awakened the memory of a suicide-attempt, as was subsequently shown through psychoanalysis. With *angel* the image of death and the hereafter immediately appeared, this time with persisting feeling-tone that hindered the subsequent reactions in a way shown by the decrease in reaction-times. All four reactions showed themselves to be amnestically blocked.

[657] The theory of our phenomenon is closely related to the teaching of Freud, whose psychological depth and fertility are still not sufficiently appreciated, in particular by psychiatrists. Freud says in effect that forgetting is frequently caused by the feeling of unpleasure associated with the forgotten image, i.e., one is inclined to forget what is unpleasant and what is associated with the unpleasant.[10] The process underlying this forgetting is the repression of the affect of unpleasure which one can observe every day in hysterical cases. “Systematic” forgetting plays, as I have shown,[11] an important part in the origins of the so-called Ganser’s twilight state. Up to now only Riklin[12] has taken up my suggestion and

developed it with any result. These investigations fully confirm the correctness of Freud's teachings on this point. That just the essential matter (i.e., the repressed complex charged with unpleasure) is forgotten is the obstacle in psychoanalysis that is often the most difficult to overcome. One usually comes up against amnesia ("I don't know," "I have forgotten," etc.) where the important matter lies. The amnestic blockages in our experiment are nothing but hysterical amnesias. They also have in common with hysterical amnesia that not only what is significant is forgotten, but also related ideas which happen to coincide with the perseverating unpleasure.

[658] The reaction-words that are so easily forgotten seem like excuses; they play a similar role to that of Freud's "screen memories." When, for example, a hysterical young girl takes an agonizingly long time to react to *to kiss* with *sister's kiss* and afterwards has forgotten how she did react, it is understood without further ado that *sister's kiss* was only an evasion, which must conceal an important erotic complex. Such reactions are reminiscent of simulation (naturally, unconscious) and resemble the "screen memories" with which hysterical subjects conceal events that are of causal importance.[13] Another reason for the speedy forgetting of these reactions is their superficiality; for these words can just as well be replaced by a number of different words of an equally superficial kind. The deceptive nature of such reactions is one aspect of the well-known general impression that has so often caused hysterical subjects to be accused of conscious pretence. It should, however, be pointed out that very often the complex hidden by such an evasion is completely cut off from consciousness, since in fact hysterical subjects can *very often* only under hypnosis be shown what lies behind the suspect reaction.

[659] As the experiment shows, the incorrect reproduction has the value of a complex-characteristic. (I do not know whether irrelevant reactions are also forgotten.) It can have a positive value through its content since, as a second association to the stimulus-word and the repressed complex, it can be very useful in analysis. The same is, of course, true in research on criminal psychology. I should like to point out that, as in the association test, so also in the reproduction method, the repressed complex can betray itself in the reaction even though it is unconscious; it does so when

it is split off from consciousness, as is often the case in hysterical patients. So far as I can see, where repressed complexes are concerned the same phenomenon occurs with normal, hysterical, and catatonic subjects; in normal cases there is a brief embarrassment or momentary blockage, in hysterical cases there is the well-known arbitrary amnesia, and in catatonic cases there is a complete barrier. The psychological mechanism, however, is the same.

PSYCHOANALYSIS AND ASSOCIATION EXPERIMENTS[1]

[660] It is not easy to say in a few words what is the essence of Freud's theory of hysteria and of the psychoanalytic method. Freud's terminology and conceptions are still in the making—luckily, if I may say so, because, in spite of the amazing progress that, thanks to Freud's contributions, insight into hysteria has made in recent years, neither Freud nor we, his followers, have gained full knowledge of it. It is therefore not surprising that Freud in his most recent publication on hysteria[2] has for the most part abandoned the terminology that he had laid down in the *Studies on Hysteria*, and substituted for it a number of different and more fitting expressions. One must understand Freud's terms not as always sharply defined scientific concepts but more as opportune coinages from his rich vocabulary. Anyone writing about Freud should therefore not argue with him about words but rather keep the essential meaning in mind.

[661] Freud sees hysteria as caused by and manifesting a series of psychic traumas, culminating at last in a sexual trauma in the prepubertal period. The so-called psychogenic character of hysteria was, of course, already known before Freud. (We have to thank Möbius[3] in particular for a concise definition of the term "psychogenic.") It was known that hysteria stems from ideas marked by the strength of their affect. But it was only Freud who showed us what lines the psychological process follows. He found that the hysterical symptom is essentially a symbol for (fundamentally sexual) ideas that are not present in consciousness but are repressed by strong inhibitions. The repression occurs because these crucial ideas are so charged with painful affects as to make them incompatible with ego-consciousness.

[662] The psychoanalytic method is inseparably linked with this conception. It acknowledges the concept of repressed and therefore unconscious ideas. If we inquire from patients about the cause of their illness, we always obtain incorrect or at least incomplete information. If we had been able to get proper information as in other (physical) diseases, we should already have known a long time ago of the

psychogenic nature of hysteria. But this is just the trick of hysteria, that it represses or forgets the real cause, the psychic trauma, and substitutes for it superficial “cover” causes. We often hear from hysterics that their illness stems from a cold, from overwork, from real organic disturbances, etc. And so many doctors are fooled again and again. Others turn to the opposite extreme and allege that all hysterics are liars. So they entirely misunderstand the psychological etiology of hysteria, which actually exists only because ideas incompatible with ego-consciousness have been repressed and can therefore not be reproduced. By means of Freud’s psychoanalytic method the barriers between ego-consciousness and repressed ideas are bypassed. This method consists mainly in the patient simply telling spontaneously everything that comes into his mind (Freud called this “free association”). An elaborate description of this method can be found in Freud’s book *The Interpretation of Dreams*. Although it is theoretically *a priori* certain that all human ideas are determined, in a most wonderful way, by psychological laws, it is still easy to conceive that an inexperienced person would get lost in the maze of ideas and would finally be hopelessly caught in a blind alley. It is and will remain one of the main objections against the general acceptability of Freud’s method that the prerequisite for the practice of psychoanalysis is psychological sensitivity as well as technique, i.e., characteristics that cannot be taken for granted in every physician or psychologist. Then there is a particular way of thinking required for psychoanalysis, which aims at bringing symbols to light. This attitude, however, can only be acquired by constant application. It is a way of thinking that is innate in a poet but is carefully avoided in scientific thought, which is said to be characterized by clear-cut ideas. Thinking in symbols demands from us a new attitude, similar to starting to think in flights of ideas. These seem to be the reasons why Freud’s method has only exceptionally been understood and even more rarely practised, so that there are actually only a few authors who appreciate Freud, theoretically or practically (Löwenfeld, Vogt, Bleuler, Warda, Störring, Riklin, Otto Gross, Hellpach).[4]

[663] Freud’s psychoanalysis is, in spite of the many valuable experiences given to us by its author, still a rather difficult art, since a beginner easily

loses courage and orientation when faced with the innumerable obstacles it entails. We lack the security of a framework that would enable us to seek out essential data. Having to search haphazardly in treatment is often tantamount to realizing that one has no idea at what point to tackle the problem.

[664] The association experiment has helped us to overcome these first and most important difficulties. As I have shown, particularly in my paper "The Reaction-time Ratio in the Association Experiment,"[5] complexes of ideas referred to as emotionally charged are shown up in the experiment by characteristic disturbances, and their presence and quality can be inferred precisely from these disturbances. This fact is known to be the basis of the "psychological diagnosis of evidence" inaugurated by Wertheimer and Klein,[6] Hans Gross,[7] and Alfred Gross,[8] an apparently not unpromising method of diagnosing from the associations the complex underlying a crime. Everybody, of course, has one or more complexes that manifest themselves in some way in associations. The background of our consciousness (or the unconscious) consists of such complexes. The whole material that can be remembered is grouped around these. They form higher psychic units analogous with the ego-complex.[9] They constellate our whole thinking and acting, therefore also our associations. With the association experiment we always combine a second, which we call the reproduction test.[10] This test consists in making the subject state how he responded to each stimulus-word in the first test. Where memory fails we usually find a constellation through a complex. The reproduction technique also allows a more detailed description of the complex-disturbances.

[665] Every psychogenic neurosis contains a complex that differs from normal complexes by unusually strong emotional charges, and for this reason has such a constellating power that it fetters the whole individual. The complex, therefore, is the *causa morbi* (a certain disposition is, of course, presupposed!). From the associations we can often quickly recognize the nature of the complex, thereby gaining important starting points for causal therapy. A by-product, not to be underestimated, is the increased scientific insight that we obtain into the origin and intrinsic

structure of psychogenic neuroses. The essence of these insights has, of course, already been given us long since by Freud, but here he is far too advanced for the understanding of his time. I may therefore be allowed to try to open up new avenues to Freud's body of knowledge. In the papers of the Diagnostic Association Studies published so far, Freud's principles have already been repeatedly used to explain various points. In the present paper I propose to illustrate the connection of psychoanalysis with the association experiment by means of practical examples. I am choosing a common case of obsessional neurosis which I treated in June 1905.

[666] Miss. E. came to me for hypnotic treatment of insomnia, which she had had for four months. Besides sleeplessness, she complained of an inner restlessness and excitement, irritability towards her family, impatience and difficulty in getting on with people. Miss E. is 37 years old, a teacher, educated and intelligent, has always been "nervous," has a mentally defective younger sister; father was an alcoholic. Present condition: well nourished, no physical abnormality detectable. Patient makes numerous conspicuously restless and twitching movements. When talking she rarely looks at the doctor, mostly speaks past him, out of the window. Occasionally she turns even further round, often laughs unintentionally, frequently makes a shrugging movement with the shoulder, as if shaking off something repulsive, simultaneously stretching the abdomen forward in a peculiar way.

Her history is very incomplete and vague. One learns that she had been a governess abroad, and was not then ill. The illness started only in recent years and developed gradually to the present climax. She had been treated by various doctors without any success. She now wanted to try hypnosis, but she had to say at once that she was firmly convinced hypnosis would not be successful. Her illness was incurable and she was sure to go mad. She had in any case repeatedly thought that she was not normal, she must already be mad. Here it was obvious that the patient was apparently talking around something that she either did not want to or could not say. On urgent questioning she declared at last, with many defensive movements and persistent blushing, that she certainly could not sleep, because each time she started going off to sleep the thought came that she certainly would not be able to sleep, she would never be able to sleep until she was dead; then she promptly woke up again and could not sleep any more for the rest of the night. Each time she felt tired and again wanted to sleep, a tremendous fear that she would never again be able to sleep until she was mad or dead woke her up afresh. She had a great struggle to bring herself to this explanation, making numerous defensive gestures, which almost gave the impression that she had something sexually indecent to tell and was ashamed of it. Here again the abdominal movements became noticeable. She repeatedly giggled in a coy way. As this gave an inadequate picture of her condition, I was led to ask whether there were any other ideas that tormented her during her sleeplessness. "No, I don't remember anything else—everything is mixed up—oh, there are thousands of things going through my head." She could not, however, produce any of them, made defensive gestures and suddenly said: In any case, she often had such silly thoughts that they actually overcame her and she could not get rid of them whatever efforts she made. She regretted that she could not tell me these thoughts, because she was afraid that I might also be overtaken by such obsessional ideas. Once before she had told a priest and a doctor about some of her thoughts, and she had always had the compulsive idea that she must have infected those people with them, so that they too had obsessional ideas. She had certainly already infected me. I reassured her; I had already heard many such ideas and it had not done me the slightest harm. After this statement she confessed, again with those peculiar defensive gestures, that besides the idea that she had infected the priest and the doctor with obsessional ideas she was tortured by the thought that a woman neighbour who had recently died had, on her account, died without the last sacrament and was having to suffer all the tortures of hell. She had had this idea only since the death; before that she had for several years had the idea that a boy whom she had brought up had afterwards died from the beatings that she had occasionally given him. The fear had tortured her so much that she had twice been obliged to write to the pupil's family to ask how he was. Each time she had done it in quite a casual manner. The good news that she had received on each occasion had calmed her down for the time being, but a few days later the fear was upon her again. This idea had now vanished, but instead she had to blame herself for the death without extreme unction of the neighbour. Her common sense told her that these ideas are nonsense (she said this with a very uncertain voice), but perhaps it was not (she quickly added). Thus she did not correct it completely, but was apparently entirely dominated by the obsessional idea.

The anamnesis did not reveal any sexual abnormalities; i.e., anything that might refer to sexual processes was immediately rejected.

An attempt at hypnosis was frustrated because she could not keep her eyes fixed on anything. In order not to compromise this method from the very beginning by useless trials, I decided first to obtain some information about the psychic material underlying the condition. I therefore carried out the association experiment with her.

1. The Association Experiment

[667] Here is the whole test:[11]

Stimulus-word	*Reaction*	*Reaction-time (secs.)*	*Reproduction*
1. *head*	*thoughts*	2.2	*hair*
2. green	grass	1.8	+
3. *water*	*drinker, to drink*	2.4	*glass*
4. to prick	needle	3.6	+
5. angel r.	heaven	2.6	+
6. long r.	short	4.0	+
7. ship	sea	1.4	+

[668] I cannot give a complete analysis of the associations. In answer to all questions the patient confined herself to saying that nothing special had come to her mind at the critical points. It was thus impossible to find the determinant of the reactions by means of subjective analysis. The objective result of the experiment was, however, sufficient to diagnose the complex, at least in outline, independent of the information given by the patient. I should like to explain in as much detail as possible how I came to this diagnosis.

[669] In anticipation, I should mention that the probable mean (Kraepelin) of all the reaction-times of the experiment is 2.4 seconds. This mean is

definitely too high for an intelligent and educated person. The mean obtained for twelve educated subjects is 1.5 secs. Since it is mainly emotional influences that prolong the reaction-time,[12] we may infer, from this high figure, a rather strong emotionality in the patient. The reader is asked to keep in mind this figure of 2.4 secs. during the following discussion of the reactions.

[670] 1, *head / thoughts,* is wrongly reproduced. The complex of the illness may have had an influence here.

[671] 3, *water / drinker, to drink,* shows a verbal deviation: *drinker* has been corrected to *to drink*. The father was a heavy drinker. The three following reaction-times are all longer than 2.4 secs.; furthermore, there are two stimulus-word repetitions. From *drinker* a perseverating emotional charge may be assumed.[13]

[672] 5, *angel / heaven*, may have recalled the obsessional idea of the neighbour who died without the sacrament.

8. to plough	to sow	2.2	+
9. *wool*	*to spin*	3.4	_[14]
10. *friendly*	*loving*	3.6	*good*
11. *table*	*woman*	4.6	−
12. to ask	to reply	2.4	+
13. state	church	2.2	+
14. *sulky*	*brave*	1.8	*friendly*
15. stalk	flower	1.8	+

[673] What disturbance prolonged the reaction time of *wool* I cannot say. Experience shows that *friendly* (10) very easily produces erotic reminiscences. The remarkable *table / woman* (11), which the patient cannot explain, seems to point to the erotic significance of R.10. Sensitive people, as all neurotics are, always take stimulus-words personally. It is therefore easy to assume that the patient would like to be the “loving, good woman.” That the word *friendly* has a certain tendency to be reproduced becomes apparent from its reappearance in 14.

(Feeling-toned ideas have, of course, a stronger tendency to be reproduced than others.)

16. to dance	to jump	1.8	+
17. lake r.	water	2.4	+
18. ill	healthy	2.0	+
193. pride	haughty	5.0	+
20. to cook	to roast	2.0	+
21. ink	pot	2.0	+
22. *wicked*	*good*	3.0	–
23. needle	prick	2.2	+
24. to swim	water	2.0	+
25. journey	railway	2.2	+
26. blue	red	1.8	+
27. bread	knife	2.0	+
28. *to threaten*	*naughty*	8.0	–

[674] *To dance* (16) tends to arouse erotic reminiscences. This assumption is not unjustified here because the following reaction is disturbed.

[675] *Ill* (18) and *pride* (19) may easily have been taken personally. *Pride* shows distinct complex-characteristics, *wicked* (22) and *to threaten* (28) obviously aroused feelings too. The response *naughty* to *to threaten* sounds like an association to a child's idea. Has a schoolgirl's reminiscence perhaps been aroused here? *To threaten* can in any case arouse many feeling-toned associations. People with lively complexes are usually somehow afraid of the future. One can therefore often see that they relate *to threaten* to the threatening uncertainty of their future. Naturally, there are often underlying concrete associations as well. One must not forget that a word like *threaten* is seldom used; owing to this "difficulty" it has a somewhat exciting influence; this does not necessarily mean that a complex underlies it. It seems to me wiser, however, to consider the influence of a complex than of a "difficulty." (Cf. Freud's analyses!)

29. lamp	light	1.8	+
30. rich	poor	1.8	+
31. tree	green	1.2	+

32. to sing	to dance	2.0	+
33. pity	poor	2.0	+
34. *yellow*	*flower*	4.2	*green*
35. mountain r.	work[15]	2.8	+
36. *to play*	*children*	2.2	*to dance*
37. salt	bread	2.8	+
38. new	old	1.6	+

[676] *To dance* (16), mentioned in the previous sequence, returns here twice, thus revealing a clear tendency to be reproduced, in accordance with its not inconsiderable emotional charge. In this way frequent repetitions can give away a great deal. A gentleman whom I had asked to be a subject for the experiment was convinced he would not give away any complexes. On the way to me he worked out what he would answer to my stimulus-words; it occurred to him at once that he would say “Paris,” a word that seemed to him to have absolutely no personal meaning. True enough, he repeated “Paris” many times during the experiment, declaring this word to be absolutely fortuitous. Six months later he confessed to me that at the time of the test he had still been under the impression of an event that had strongly affected him and which had occurred in Paris. At that time, however, he had thought that Paris had no significance at all for him. I have no reason to doubt this man’s truthfulness. *Yellow* (34) certainly had a personal effect, judging from the surrounding complex-disturbances. The patient has a sallow elderly complexion. Women are very sensitive to such things, particularly if an erotic complex is present.

[677] That *children* (36) is not reproduced but replaced by another erotic term seems to be worth mentioning.

39. *habit* r.	*nasty or bad*	12.2	*vicious habit*
40. to ride r.	to drive	2.4	+
41. *wall*	*room*	3.0	–
42. *silly* r.	*clever*	2.8	–
43. exercise-book	book	3.0	+
44. *to scorn*	*disdain*	15.2	*to despise*
45. tooth	abscess	1.4	+

[678] In this sequence we meet several serious complex-disturbances. With *habit* (39) and *to scorn* (44), the patient made defensive movements and stamped her foot. An "ugly" or "bad" habit can easily be interpreted in a sexual sense: e.g., masturbation is a "nasty" habit, a "vicious habit." People indulging in such "vicious habits" are "scorned."

[679] *Silly* (42) may be personal or may still belong to the range of the emotional charge perseverating from *habit*. Here her gestures by no means contradict a sexual complex. *Habit* could in some circumstances also mean "the drink habit" and thus have aroused the complex of the drunkard father.

46. *correct* r.	*I should always like to say just the opposite*	7.6	*incorrect*
47. people r.	father	6.0	+
48. to stink	fragrance	4.8	+
49. *book* r.	*pen*	4.4	*exercise-book*
50. *unfair* r.	*sense*	3.6	*fair*
51. frog	green	2.4	+
52. to separate	marriage	2.2	+
53. hunger	thirst	1.4	+
54. white	black	1.8	+

[680] If the patient, as we assume, takes the stimulus-words personally and has an erotic complex as indicated, then it is understandable that to *correct* (46) "she would always like to say the opposite," as this fits her behaviour; it also fits the father's dipsomania. Ideas that are determined twice or more do not exclude each other; according to Freud they are even the rule.

[681] That *people* (47) is associated with *father* is striking. The reaction seems to be within the field of the emotional charge of *correct*. This could lead to the conclusion that there is some connection, unclear up to now, between her self-reproaches and *father*. (This connection will become clear later on.)

[682] What sort of interference acted on *book / pen* (49) is not easy to say. *Book*, pronounced as it is spelled [*Buck*], means "belly" [*Bauch*] in the

Swiss dialect. In a sexual complex such an assimilation could easily occur. I have seen it repeatedly in other subjects.

[683] The consistent decrease of the reaction-times from *correct*, 7.6 secs., however, indicates a serious complex-interference that begins with this stimulus-word and gradually decreases during the next seven reactions. *Unfair* (50) seems to have been taken personally, and this fits well with her self-recrimination.

55. cattle r.	cow	4.2	+
56. to attend	disobedient	4.0	+
57. *pencil*	*to sharpen*	3.0	*pointed*
58. dull	weather	1.8	+
59. plum	tree	3.8	+
60. to meet	certain	1.4	+
61. law	state	2.8	+
62. *dear*	*good*	4.0	*child*
63. glass	wa-water	1.6	+
64. *to quarrel*	*argument*	2.4	*discord*
65. *goat*	*milk*	2.0	*to milk*

[684] I have no explanation for the disturbance at 55, *cattle. Disobedient* (56) reminds one of the previous *naughty*, which may be related to the pupil already mentioned. The disturbance of the following unrelated reaction indicates the perseverating emotional charge. R.59, *plum / tree*, does not seem to have passed by smoothly, judging by the length of the reaction-time. The word here used for *plum* is not an everyday word; it is, however, unlikely that for this reason it takes an educated subject such a long time to react. (Wehrlin’s idiots have average figures varying between 3.0 secs. and 37 secs. Therefore 3.8 seems far too long for an educated person.) The German *Pflaume* (plum) is, like Swiss *Zwetschge* (plum), a popular sex-symbol in our colloquial language.

[685] *Dear* (62) can easily indicate an erotic complex. At *glass* (63) the complex of the dipsomaniac father apparently comes to the surface again with the strong emotional charge attached to it (hence the disturbance of the two following reactions).

66. large	small	2.6	+
67. potato r.	floury	6.0	+
68. to grind	mill	2.0	+
69. part r.	small	11.6	+
70. *old*	*ugly*	3.0	*young, unattractive*
71. *flower*	*beautiful*	2.0	*scent*
72. *to beat*	*rod*	2.8	–
73. cupboard	table	2.8	+

[686] *Large* (66) is as a rule taken personally. The patient is very short. With an erotic complex, she is, as we have already seen, bound to be much concerned with her body. This might explain the disturbance of the following reaction.

[687] For *part* (69), the reaction-time is very much extended. It is usual to interpret "part" as "genital." Here the strong emotional charge is characteristic for this association. It is not surprising under this constellation that *old* (70) is given a personal erotic meaning. How strongly emphasized in this patient is the question of physical beauty and her own ageing can be seen from the perseveration *beautiful* (71). *To beat / rod* (72) can again have been specially constellated by the obsessional idea that she had caused her pupil's death.

74. wild	child	2.4	+
75. family	large	2.4	+
76. to wash r.	to clean	3.0	+
77. cow	to milk	1.8	+
78. stranger	nostalgia	14.8	+
79. happiness r.	unhappiness	3.0	+
80. to tell	story	1.6	+

[688] The minor disturbance at 76, *to wash*, can be explained by the preceding erotic concepts *child* and *family. Stranger* (78) apparently aroused a personal association, to be explained later on.

81. propriety	intellect	4.6	+
82. narrow r.	small	3.2	+
83. brother	sister	1.0	+

84. damage r.	neighbour	4.0	+
85. stork r.	church	2.4	+
86. false r.	unfaithful	3.0	+
87. fear	anxiety	2.4	+
88. to kiss	mouth	2.2	+
89. fire	blaze	1.8	+
90. dirty	sticky	2.2	+
91. door	fold	1.6	+

[689] The sound association of 81, *propriety / intellect (Anstand / Verstand*) is most striking. Let us remember the disturbances produced by *habit!* There we suspected the “vicious habit” of masturbation. Here too this complex could have been aroused. In this case *intellect* is not fortuitous. According to a popular belief masturbation destroys the reason, the “intellect.” One has also to bear in mind the patient’s bemoaning that she is afraid of losing her reason.

[690] *Narrow / small* (82) is still under the influence of the preceding reaction: *small* probably belongs to the body-complex in view of its being repeated (66); *narrow* may, under the constellation of the preceding association, refer to the *introitus vaginae* and therefore be connected with *small*, which indicates her figure; the ominous “part” too is *small* (this assumption will be confirmed). *Damage* (84) is probably taken personally; *neighbour* fits neatly. She has done immense damage to the neighbour by being guilty of her dying unabsolved. Under the sexual constellation, however, “damage” can also have been taken personally; one does personal and mental damage to oneself by masturbation (see above). The neighbour then provides a cover (see Freud’s similar conclusions). Behind the neighbour the patient herself may be hidden. That an emotional charge interfered here becomes apparent from the following disturbances. At 86, *false / unfaithful*, a definite erotic reminiscence can easily have come to the surface in an elderly spinster.

92. to choose r.	teacher	4.4	+
93. hay	straw	1.8	+
94. *still*	*stool*	13.0	*child*
95. mockery	scorn	1.4	+

96. to sleep r.	to wake	3.4	+
97, month	year	1.6	+
98. coloured	gaudy	2.4	+
99. dog	cat	1.2	+
100. to talk	to be silent	1.4	+

[691] To *to choose* (92) women like to associate the thought of marriage.

[692] The patient's father was a teacher. She is a teacher. It would be easy to assume that she has marriage with a teacher in mind. The father-complex may, however, also have to be considered here (see below). *Still / stool* (94) is a striking sound association. The explanation is given by the erotically charged term *child*. A child can be "still"; but the dead are also still (obsessive idea: she has caused the pupil's death by ill-treating him). Behind this there may be erotic connections, associated with German "stillen" (to suckle). (Cf. 49, *book*, and subsequent comment.) The same word (*stillen*) can be used for quieting a child or quieting sexual desire. To *sleep* (96) has many erotic associations. The patient cannot sleep, for instance; sleeplessness in younger people, however, is often the expression of lack of sexual satisfaction (Freud). Anyone inexperienced in the field of pathological association psychology will probably shake his head at the above suppositions; he will perhaps see in them not just hypotheses but sheer phantasms. The judgment on them will perhaps be the same as on Freud's *Interpretation of Dreams*.

[693] Let us next summarize the result of the association and reproduction test. As I have already said, the patient did not give any information about herself; I am therefore entirely dependent on the objective data of the test and on my experience.

[694] The probable mean of the reaction-times is 2.4 secs. Forty-four per cent of the reaction-times exceed 2.4 secs. Amongst these are figures of up to 15.2 secs., pointing to the dominance of emotion or, in other words, a considerable lack of control of the psychic material.

[695] In the analysis we indicated the existence of various complexes. The erotic complex appears to play a dominant role. Here I give a tabulated

survey of the complex-reactions. The following examples should be understood as related to an erotic complex:[16]

10. *friendly*	*loving*	3.6	*good*
11. *table*	*woman*	4.6	−
12.		2.4	
13.		2.2	
14.		1.8	
16. to dance	to jump	1.8	+
17. lake r.	water	2.4	+
34. *yellow*	*flower*	4.2	*green*
35. mountain r.	work[17]	2.8	+
36.		2.2	
39. *habit* r.	*nasty or bad*	12.2	*vicious habit*
40. to ride r.	to drive	2.4	+
41. *wall*	*room*	3.0	–
44. *to scorn*	*disdain*	15.2	*to despise*
45.		1.4	
59. plum	tree	3.8	+
62. *dear*	*good*	4.0	*child*
66. large	small	2.6	+
67. potato r.	floury	6.0	+
68.		2.0	
69. part r.	small	11.6	−
70. *old*	*ugly*	3.0	*young, unattractive*
71. *flower*	*beautiful*	2.0	*scent*
72. *to beat*	*rod*	2.8	−
73.		2.8	
74. wild	child	2.4	+
75. family	large	2.4	+
76. to wash r.	to clean	3.0	+
81. propriety	intellect	4.6	+
82. narrow r.	small	3.2	+
83.		1.0	
86. false r.	unfaithful	3.0	+

87.		2.4	
88.		2.2	
89.		1.8	
92. to choose r.	teacher	4.4	+
93.		1.8	
94. *still*	*stool*	13.0	*child*
95.		1.4	
96. to sleep r.	to wake	3.4	+
97.		1.6	

[696] These associations, which presumably have a sexual background and which show all the characteristic complex-disturbances, could be interpreted as follows:

[697] The patient feels herself to be old and ugly, is very sensitive about her sallow complexion, above all pays anxious attention to her body; in particular she does not like being so small. Presumably she has a great desire to get married; she would certainly be a loving wife to her husband and she would like to have children. Behind these not very suspicious erotic symptoms, however, there seems to lie a sexual complex that the patient has every reason to repress. There are signs that allow the conclusion that she pays more than usual attention to her genitals. In a well brought-up and educated woman this can only refer to masturbation; masturbation, however, in the wider sense of a perverse self-satisfaction.

[698] Masturbation is one of the most frequent sources of self-reproach[18] and self-criticism. This complex, or, better, this aspect of the sexual complex, is also indicated by the following associations:

14. *sulky*	*brave*	1.8	*friendly*
19. pride	haughty	5.0	+
22. *wicked*	*good*	3.0	−
23.		2.2	
24.		2.0	
42. *silly* r.	*clever*	2.8	−
43. exercise-book	book	3.0	+
46. *correct* r.	*I should always like to say just*	7.6	*incorrect*

	the opposite		
47. people r.	father	6.0	+
48. to stink	fragrance	4.8	+
49. *book* r.	*pen*	4.4	*exercise-book*
50. *unfair* r.	*sense*	3.6	*fair*
51.		2.4	
52.		2.2	
53.		1.4	

[699] To the complex of the alcoholic father can be related:

3. *water*	*drinker, to drink*	2.4	*glass*
4.		3.6	
63. glass	wa-water	1.6	+
64. *to quarrel*	*argument*	2.4	*discord*
65. *goat*	*milk*	2.0	*to milk*

[700] From this tabulation it can be seen that the sexual complex is well in the foreground. Although, as I have already mentioned, a direct confirmation of this interpretation was not to be had from the patient, I took the complex-diagnosis as confirmed for the reasons I have just given.

[701] I told her therefore that I was sure her obsessional ideas were nothing but excuses and shiftings, that in reality she was tortured by sexual ideas.

[702] The patient denied this explanation with affect and sincere conviction. Had I not been convinced through the association experiment of the existence of a particularly marked sexual complex, my certainty would probably have been shaken. I appealed to her intelligence and truthfulness: she assured me that if she knew of anything of the kind she would tell me, because she well knew it would be silly to conceal such thoughts from the doctor. She had thought of getting married, “as everyone else did, but not more.” After this I let the patient go and asked her to come again in two days’ time.

2. PSYCHOANALYSIS

[703] For psychoanalysis the patient’s mental condition is important, but still more important is the mental condition of the doctor. Here probably

lies the secret of why Freud’s psychoanalysis is disregarded by the world of science. He who approaches a case with anything but absolute conviction is soon lost in the snares and traps laid by the complex of hysterical illness at whatever point he hopes to take hold of it. One has to know from the very beginning that everything in the hysteric is trying to prevent an exploration of the complex. Where necessary, not only the patient’s interest and his regard for the doctor fail, but also his thinking, memory, and finally even his language. But precisely these peculiar defence-mechanisms give the complex away.

[704] Just as hesitating, faulty reproduction and all the other characteristic disturbances always occur in the association experiment whenever the complex is touched on, so in the analysis difficulties always arise whenever one gets close to the complex. In order to bypass these difficulties, Freud, as is well known, induces “free associations.” It is a very simple method and one has only to practice it for some little time to become reasonably familiar with it. In this case I carried out psychoanalysis strictly on Freud’s lines. I made the patient take an easy-chair and sat down behind her, so as not to confuse her. Then I asked her to tell me calmly everything that came into her mind, no matter what it was about. The patient laughed; surely one could not say every piece of nonsense that came into one’s mind. But I adhered to my request. Then she tried several times to say something, suppressed it, however, each time with the excuse that it was silly—I would laugh at her and think she was an ungrateful person who could only offer banalities. I did nothing but encourage her to continue to talk and eventually the patient produced the following sentences: “I think I shall never get well—now you are sure to laugh—but I am convinced that I shall never get well—you cannot hypnotize me—you will no more cure me than any other doctor has—it will only get worse, because now I have to reproach myself that with my nonsense I am only unnecessarily wasting your time.” This idea was not quite unjustified because the patient always blurted out the sentences after long intervals, so that it took us almost half an hour to come to this meagre result. She continued: “I am thinking now of my people at home, how hard they work and how they need me; while I am here, good for nothing but my silly ideas—you too will certainly become

infected by them—now I am thinking that I cannot sleep, that last night I took 1 g. of Veronal, although you have forbidden it—I am sure I shall never be able to sleep. How can you expect to cure me?—What do you want me to tell you? [Here a certain restlessness became noticeable.] But I cannot tell you every piece of nonsense that comes into my head. [Increasing restlessness, shrugging of the shoulders, makes stamping movements with her foot now and then, shakes herself as if in great indignation.] No, this is nonsense—I don't know of anything else now—really, I don't know of anything else. [Very restless, wriggles and turns in her chair, makes defensive movements by shaking her thorax to and fro and makes elbow movements as if pushing something away.] At last she jumps up and wants to go, she cannot think of anything else at all! With gentle force I make her sit down in the chair and remind her that as she has come to me to be cured, she must follow my directions. After a long debate on the use and purpose of my method, she at last consents to stay and continue, but soon the movements of indignation and defence are resumed, she literally wriggles in the chair; occasionally she straightens herself with a forcible movement, as if she had come to a decision after the greatest struggle with herself. At last she says meekly: "Oh, something silly came into my head—you are sure to laugh—but you must not tell anybody else—it is really nothing—it is something quite simple—no, I can't tell you, never—it has nothing at all to do with my illness—I am only wasting your time with it—really, it doesn't mean anything at all—have I really got to tell it? Do you really insist on it? Oh, well, I may as well tell you, then I shall be rid of it. Well,—once I was in France—no, it's impossible, and if I have to sit in this chair for another four weeks [with sudden determination] well, I was a governess in France—there was also a maidservant—no, no, I cannot tell it—no, there was a gardener—for goodness sake, what will you think of me? This is really sheer torture—I have certainly never thought of such a thing!"

[705] Between these painful ejaculations the following story at last emerged with innumerable stoppages and many interruptions, during which she asserted that this was the first and last session with me.

[706] Her employer also had a gardener, who once said to her that he would like to sleep with her. While saying this he tried to kiss her, but the

patient pushed him away. When she went to bed that evening she listened at the door and wondered what it would be like if he did come to sleep with her; then a frantic fear overtook her that he might really come. Once in bed she was still compelled to think of what it would be like if he came, then reproached herself anew for thinking such things. The thought of what it would be like to sleep with the gardener did not, however, leave her, although she was again and again shocked at finding herself capable of such thoughts. In this mental turmoil she was unable to get to sleep until the morning.

[707] The first session took no less than an hour and a half. Its result was a sexual history! What was particularly interesting to me was its quite spontaneous appearance with the same gestures that I had immediately noticed in the patient at the first consultation. These tic-like phenomena had a very close and easily understandable connection with the repressed sexual matters! I arranged the following session for two days later, which was at once accepted, the patient looking very relieved and not saying another word about leaving.

[708] On the day of the appointment I was busy with some urgent work when the patient came and therefore sent her a message, asking her to come in the evening instead. She, however, sent the reply that she could not possibly wait, she had to speak to me urgently. I thought something special had happened and went to her. I found her in great distress: she had not slept at all, not a minute, she had had to take drugs again, etc. I asked her whether she had been brooding again over her obsessional ideas: "No, something much worse; now I have my head full of that nonsense that I told you about last time. Now I can think only of these stories and therefore cannot close an eye; because of them I toss and turn all night long and cannot get rid of these thoughts for a minute. I have definitely got to talk to you now; it gives me no peace." She went on to tell me that last time she had gone home very much relieved and calmed down, almost in a gay mood, and had hoped she would now at last be able to sleep, but then a story came into her mind that she should have told me last time, but which she had thought was not really of any importance. She had determined now not to "act so silly" as last time, but freely to tell everything she thought of. Then the confession would soon

be over. So I resumed the analysis, hoping it would go off smoothly without the endless preliminaries of the time before. I was, however, completely mistaken. The patient repeated the interjections of the first session almost verbatim. After an hour and a half of mental torture I brought the following story to light: In the same house where the patient was a governess, there was also a maid[19] who had a lover, with whom she had sexual intercourse. This girl had also had sexual intercourse with the gardener. The patient often discussed sexual topics with her and in particular the sex life of master and mistress. The patient and the maid even investigated their beds for sperm stains and other signs of sexual intercourse! Every time, after such amusements, the patient suffered the severest self-reproaches on her indecency and spent sleepless nights, during which she turned and tossed about because of torturing reproaches and voluptuous fantasies.

[709] When, after tiresome resistance, the story was out at last, the patient declared: now she had come to the end, this was all, nothing else came to her mind now. If only she could sleep; the telling of these stories did not help at all.

[710] Two days later she came to the third session and said: After the previous session she had been rather quiet again, but as soon as she was in bed at night another new story had come to her mind which had tortured her incessantly, with the obsessive reproach that again she had not told me everything in the session. She was sure now that today she could tell me the story quickly, without the continuous resistance as in the first two sessions. The third one, however, proceeded exactly in the same way as the two previous ones: incessant interjections, excuses, etc. Particularly conspicuous was the tendency to present the matter as perfectly natural, as if there was nothing to it. It was about a second maid who was in service with the same employer. The master had a valet who pursued the girl. He did not, however, succeed in seducing her. At last, one evening, when there was a party in the house, he managed to entice the girl into the garden. The couple was, however, surprised by the mistress at the critical moment. At this the youth is said to have exclaimed: What a pity, he was just ready! The patient heard this story from the first maid. At first she made out not to have the slightest interest

in the story, as if she found it downright repulsive. This, however, had been a lie, because in fact she had had the greatest interest in it; she had several times tried to bring the maid back to this topic in order to hear every detail. At night she had hardly been able to sleep from curiosity, and had incessantly had to ask herself the questions: What did the two want in the garden? In what posture could they have been found by the mistress? What had the youth been ready for? What would have happened if the mistress had not come? Although she knew the answers perfectly well, she could not stop asking herself these questions over and over again. At last she was compelled to think over persistently what she would have done in such a situation. This excitement lasted for several days.

[711] We have mentioned being struck by her matter-of-fact presentation of the story. She said, for instance, very reluctantly that the lad was after the maid. From the reluctance it could be expected that something rather unpleasant was to come, but she continued as follows in an indifferent tone: “The lad was just in love with the girl. This is nothing unusual? This happens often?—oh, now there is something again—no, that I cannot—” etc. While telling the story she always tried from time to time to belittle and talk herself out of her belief in the importance of an event by inserting such generalizing rhetorical questions.

[712] From now on, during the whole period of the analysis (three weeks), the original obsessional ideas were absent; their place had been taken by sexual ideas. The memories underlying the obsessional ideas that had already been dealt with constantly tormented the patient. She was so obsessed by these sexual reminiscences that she was never able to find peace until she had told the story again. She expressed great amazement at this change; the stories came like beads on a string, as if they had been experienced yesterday. Things occurred to her of which she had previously been quite unconscious but which she now again recalled (Freud’s hypermnesia). Of course, these admissions have to be taken with the same reserve as the familiar “I don’t know.” The patient may quite well have ardently cultivated all her sexual ideas without remembering them, and spun them out right up to the moment when she had to speak about them objectively. In her stories one can often see immediately what

is to come from her gestures, while she still repeatedly asserts that she certainly does not remember anything more. Her everyday person and her sexual person are just two different complexes, two different aspects of consciousness that do not want to or must not know anything of one another. The split of the personality here is, however, only hinted at (as in every vigorous complex, the peculiarity of which is a striving for autonomy). But it is only a step to the classic examples of split personality, all of which are, of course, produced by the mechanisms demonstrated by Freud.[20]

[713] With these three sessions a certain conclusion was reached, in so far as one could not avoid relating the obsessional idea that she had caused the death of her former pupil to the self-reproaches connected with the sexual stories. This apparently was also felt by the patient when she spontaneously mentioned that many years had already passed since these events, and the thought that she had caused the pupil’s death had long ceased to torment her. Probably for the purpose of escaping from the unbearable sexual ideas, she transferred the guilt from this field to that of her educational methods. The mechanism, which is well known, is this: if one has continually to reproach oneself in one sphere, one tries to compensate for these deficiencies in another sphere, as if the same deficiencies were present there as well; this is particularly obvious in masturbators (compulsive brooding, cleanliness, and orderliness). It therefore seems to be not incidental that precisely these stories, underlying a past obsessional idea, were told first. Since there were in present consciousness no obsessional ideas directly supported by these stories, there were no special resistances present. Hence, the stories were relatively immaterial.

[714] I refrain from presenting the subsequent sessions in detail; they all followed the pattern already described. No admonition, no pointing out the absurdity of her stereotyped resistance, could make the patient talk more quickly and spontaneously. Every new session was a new torture, and at almost every one the patient declared that this was the last. Usually during the following night, however, there came new material that tormented her.

[715] The reminiscences of her time as governess were succeeded by a series of unsavoury stories that had served as a topic for conversation with the neighbour for whose death without the sacraments the patient reproached herself. The neighbour was a person about whose dubious past a number of rumours were current. The patient, who is a very decent girl and comes from a respectable family, known to me, had in her own view a dubious past herself and reproached herself for it. Therefore it is not surprising, psychologically, that she was immediately attracted by the interesting neighbour. There the *chronique scandaleuse* of the day used to be discussed, and in this connection the patient had quite a number of obscene stories and jokes to tell me, which I need not repeat here. For this also she reproached herself. When the neighbour quickly succumbed to an illness, the patient transferred the reproaches, which actually were about her sexual curiosity, to the death of the neighbour, who had died without absolution because the patient had during her visits enticed her to sinful conversations. The type of reminiscence and of reasoning seems to suggest that this obsessional idea is simply a new version of the earlier obsession about the death of the pupil. The religious obsession took her first to the priest and then to the doctor. She felt that she had infected both of them with her obsessions. She had therefore done something similar to what she had done to the neighbour whom she had destroyed simply by being what she was, as she had originally also destroyed the pupil. Underlying all this is the general idea that she is a horrible creature who infects everything with her depravity.

[716] During the following sessions the patient dealt mainly with a series of stories that she had recently discussed with a girl friend. The friend has an office job in a big shop. There she hears quite a number of juicy things from the men, each of which she retails to the patient while they are still warm. On one occasion the friend said she intended to have sexual intercourse just simply to see what it was like. This thought mightily excited the patient; she told herself incessantly that she too would like to have it. This, however, was sufficient reason for renewed self-reproaches. From this incident onwards there was an increasingly clear trend towards referring sexual subjects to herself; during almost every session obscene jokes and the like had to be told again. From the

ideas referring to herself there came first all the reminiscences of former love-affairs and longings for affection. The recounting of these on the whole rather harmless events went off fairly smoothly. Only one incident had a stronger emotional charge. She was in love with a young man about whom she knew very little and thought he was going to marry her. Later, however, he left her without a goodbye and she never heard from him again. For a long time she kept on waiting for him and always hoped he would write to her. To this refers 78, *stranger / nostalgia*,[21] 14.8 secs. As already mentioned, the patient could not then explain the significance of this reaction. While the old love stories were told without any major difficulties, once this phase had passed resistance set in. The patient definitely wanted to leave, she had no more to tell. I told her that I had not heard anything about her earlier youth. She thought she would soon be finished with that, there was not much to tell about her youth. She had hardly finished this sentence when she was compelled to repeat several times her vehement tic-like defensive gestures, an unmistakable sign that much more very important material could be expected. With the greatest resistance and the most painful contortions she told in a jerky manner of a book that she had found at home, when she was ten years old, the title of which was *The Way to Happy Matrimony*. She asserted that she had no longer any idea what was in it. But as I continued to be relentless, recollections recurred after a while, and it turned out that the patient still remembered every detail, frequently even the wording. She gave a detailed account of the first sexual intercourse and its complications; the academic description without any personal reference seemed to me peculiar and unusual. I suspected that something must be concealed behind this façade. It was not long before the patient related that at the age of fourteen she had found in her elder brother’s pocket a small book in which was reprinted a letter. The letter was written by a young wife to an intimate friend and discussed the secrets of the wedding night in a very obscene and lascivious manner. Apparently I was on the right track, as this story showed. The patient’s next recollection concerned erotic dreams that she had had only quite recently. The dreams were outspoken ejaculation dreams and represented sexual intercourse undisguised. This was followed by the confession of having several times tried to hold the dream-image and to masturbate. Then it turned out that masturbation had also occasionally been practised before this. With the masturbation was linked a persistent thinking about her own genitals; she is compelled to wonder whether she "is properly built," whether perhaps she has not a too narrow introitus; she also has to investigate this state of affairs with the finger. She frequently has to look at her naked body in the mirror, etc. She has a long series of fantasies on sexual intercourse, she is compelled especially to imagine in every detail how she would behave during the first intercourse, etc. In this connection she also confesses to feeling a strong libido (which at the beginning she had emphatically denied). She would very much like to get married, and therefore attaches sexual fantasies to most of the men she meets. She also imagines herself in the leading part of all the sex stories she has collected. Thus she tells, for instance, of a naïve young acquaintance, a girl who, on a trip in a crowded railway compartment, had to sit on her teacher's lap. The girl afterwards laughingly related that the teacher never forgot his role, he even carried a ruler in his trousers pocket. About this story the patient thinks that she too would enjoy it if a teacher took her on his lap, but she would know what the ruler in the trousers pocket meant. (The previously not-completely explained reaction [92] *to choose / teacher* may have been constellated partly by this story.)

[717] With great reluctance she also admits that at the age of fourteen she had once laid herself upon her younger sister "as if she had been a man." At last, in one of the latest sessions, came the narration of an event which in every respect had the significance of Freud's youth trauma. At the age of seven or eight she had repeatedly listened to the sexual intercourse of her father and mother. Once she noticed that her mother struggled and did not at all want to let the father come to her again. For a long time after that she could not face her parents any more. Then her mother became pregnant and gave birth to her younger sister. She bitterly hated the little sister from the very beginning, and only much later was she able to overcome a deep aversion to the child. It is, of course, not quite unlikely that the patient imagined herself as one of the acting persons in this story and that she adopted the role of the mother. This very plausible

connection easily explains the strong emotional charge in all associations to the father.

[718] Of course, the psychic trauma of such an observation becomes a complex with a very strong emotional charge in a child’s mind, which is bound to constellate the thinking and acting for years to come. This was, in a classic way, the case with this patient. It gave a quite definite direction to her sexual function.[22] This becomes obvious from the analysis of her repressed material; it is always chiefly connected with digging out and imagining situations of sexual intercourse. Surprisingly, in spite of her sexually extraordinarily lively fantasy, she never became deeply involved with men and anxiously repulsed every attempt at seduction. But instead she was attracted, with an almost magical force, to doubtful females and dirty topics of conversation which, at her level of education and intelligence, one would not have expected. The two last sessions were particularly instructive in this respect. She produced the choicest selection of most repulsive obscenities that she had occasionally heard in the street. What these obscenities, the narration of which I must be spared, had in common were various abnormalities of sexual intercourse (e.g., too wide, or too narrow introitus, sexual intercourse of a little hunchback with a huge fat woman, etc.). The number and the extreme vulgarity of these jokes appeared to me almost incredible for such an educated and decent lady. The phenomenon, however, is explained by the early perverted direction of the sexual function, which is mainly concerned with finding out unclean sexual practices, i.e., the symbolic repetition of eavesdropping on sexual intercourse. This complex, caused by listening to the sexual act, has throughout her life determined a multitude of sexual actions and associations with their peculiar manifestations. This, for instance, is the reason why the patient performs a sort of sexual intercourse with her little sister, why her listening at the door to hear whether the gardener is coming still haunts her, why she has to carry out the disgusting job of examining her employers’ bed, why she has to seek the company of morally dubious people, etc. Her defensive movements and the peculiar pushing forward of the abdomen also show how the effect of the complex spreads in all

directions. It is worth noting, too, that she appears at each session in a different dress.

[719] Using the sexual function in this way is bound to be incompatible with her otherwise gently disposed character; a rejection and repression of sexuality as absurd as it is repulsive must have taken place, because it is impossible that an educated and sensitive woman can combine these obscenities with the other contents of her mind. These things can only be tolerated when repressed. But they do exist, they actually have a separate existence, they form a state within the state, they constitute a personality within the personality. Expressed in other words, there are two mental attitudes present, kept apart by strong emotional barriers. The one must not and cannot know anything of the other. This explains the peculiar disturbances of reproduction that counteract the analysis. The ethically superior mind has not the associations of the other at its disposal; she must therefore think she has forgotten these ideas and that she has never known such things. I am therefore inclined to accept that the patient was really convinced that nothing more came into her head, that it was not a lie when she asserted with the greatest persistence that she had no more to say.

[720] But even if a complex is still so far repressed, it must yet have a constellating influence on the contents of normal consciousness, for even the deepest split of consciousness does not reach the indivisible basis of the personality. Thus the repression must leave a certain imprint on the conscious processes; the normal consciousness must somehow explain away the emotional condition that a repressed complex leaves behind. What is simpler, therefore, than to produce an idea compatible with normal consciousness as an explanation for the persistently self-reproachful and discontented mood? To explain away the pangs of conscience related to the sins of the governess phase, the patient displaces her self-reproach on to her method of teaching, which she feels must have led to a disastrous result; otherwise she would not persistently experience the feeling of self-reproach when she recalls incidents of that time. As we have already seen, the origin of this obsession acts as a pattern for the obsessional guilt about the neighbour’s dying unabsolved. The accumulation of obsessive ideas about the doctor and the priest has

its good reason in the fact that these people were not at all indifferent to her sexuality, as the patient admitted to me. By having a sexual effect on her they become in a way accomplices in her wickedness; she therefore expects them to feel equally guilty.

[721] After this analysis we can understand the role, still unclear in the associations, that the father plays in her erotic complex. In general the analysis supports to the widest extent the hypotheses suggested by the associations. The associations actually served as signposts among the maze of ever-changing fantasies that at every stage threatened to put the analyst on the wrong track.

[722] The analysis was carried out every other day for three weeks and lasted one and a half to two hours at a time. Although at the end of the three weeks the patient had neither achieved proper sleep nor peace of mind, I discharged her and heard no more of her until the end of November. During the last days of November 1905 she suddenly came to see me and presented herself as cured. After the termination of the treatment she had still been very agitated for about four weeks. Sometimes she was tortured at night by her sexual images, sometimes again by obsessional ideas. In particular the obsession about the neighbour frequently recurred and did not give her any peace until she went to the daughter of the dead woman to make her tell her about the death scene for the *n*th time. When the daughter told her again, as usual, that the mother had died peacefully, the patient suddenly became convinced that the woman had after all received the last sacraments. With this all obsessional ideas suddenly disappeared. Sleep returned and was only occasionally somewhat disturbed by sexual images.

[723] What had brought about this happy ending of the treatment?

[724] It is obvious that the daughter’s story, which the patient had heard many times without any effect, was nothing but the vehicle for the final removal of the obsession. The actual turn for the better occurred at the beginning of the treatment, when the sexual images replaced the obsessional ideas. The confession of her sinful thoughts may have given considerable relief to the patient. But it seems unlikely that the cure can be ascribed entirely to their verbal expression or to the “abreaction.”

Pathological ideas can be definitely submerged only by a strong effort. People with obsessions and compulsions are weak; they are unable to keep their ideas in check. Treatment to increase their energy is therefore best for them. The best energy-cure, however, is to force the patients, with a certain ruthlessness, to unearth and expose to the light the images that consciousness finds intolerable. Not only is this a severe challenge for the patient's energy but also his consciousness begins to accept the existence of ideas hitherto repressed.

[725] The split-off contents of the mind are destroyed by being released from repression through an effort of the will. So they lose a great deal of their authority and therefore of their horror, and simultaneously the patient regains the feeling of being master of his ideas. I therefore put the emphasis on arousing and strengthening of the will and not on mere "abreacting," as Freud originally did.

[726] It appears, from some recent publications, that Freud's theory of obsessional neurosis is still consistently ignored. It therefore gives me great satisfaction to draw attention to Freud's theories—at the risk of also becoming a victim of persistent amnesia.

SUMMARY

[727] 1. The complex that is brought to light through the associations offered by patients with psychogenic neuroses constitutes the *causa morbi*, apart from any predisposition.

2. The associations may therefore be a valuable aid in finding the pathogenic complex, and may thus be useful for facilitating and shortening Freud's psychoanalysis.

3. The associations supply us with an experimental insight into the psychological foundation of neurotic symptoms: hysteria and obsessive phenomena stem from a complex. The physical and psychic symptoms are nothing but symbolic manifestations of the pathogenic complexes.

THE PSYCHOLOGICAL DIAGNOSIS OF EVIDENCE[1]

I

[728] It is a matter of common knowledge that the evidence of witnesses, that most unpredictable element in legal proceedings, has recently become the object of experimental research. Perhaps the most credit belongs to William Stern, whose extensive "Contributions to the Psychology of Evidence"[2] is a real treasure-house from both the theoretical and the practical points of view. The aim of these papers is obvious; the ultimate goal is a general improvement in human memory, the utter unreliability of which is not apparent without experiment. The reports of Stern's experiments on legal evidence have gradually found their way to most of the major universities and have thus become widely known. It is therefore probably not necessary to deal with them in detail in this paper. In Stern's school the main object of investigation is the reliability of evidence; it uses the technique of the examining magistrate for the purposes of experiment. The question, however, with which we shall deal here, though not less important from the legal point of view, is at the same time of medical and psychological significance; it concerns the "diagnosis" of a criminal case by study of the psychological make-up of the witness.

[729] This new field of research is best explained by proceeding in an historical fashion; the problem is thus most easily understood even by the layman in psychology.

[730] Wilhelm Wundt, stimulated by Galton,[3] introduced into German psychology a simple experiment which we propose to call the "association experiment." The experiment consists essentially in the experimenter calling out some random word to the subject, in reply to which the subject has as quickly as possible to say the first word that comes into his or her head. A large number of repetitions of this procedure yields a series of pairs of words which one can call *associations*.[4] The word called out is known as the *stimulus-word*, the

reply as the *reaction*. As can easily be seen, this experiment, which appears so academic, was of course originally used only for psychological purposes far remote from any practical use. The main interest lay in the logical relation of word-pairs. There were also questions on how far back one could trace the associations, and whether they had already developed in the subject at an early age or not until later in life. The first relevant German paper, by Trautscholdt, on "Experimental Investigations into the Associations of Ideas,"[5] deals exclusively with this topic. Later investigations by others of the Wundt school, such as those described in the papers by Scripture[6] and Cordes,[7] were also concerned with purely theoretical questions. The experiment produced positive results and gained practical importance only when the psychiatrists took the matter in hand. This progress is connected with three well-known names: Kraepelin, Sommer, and Ziehen. These three research workers proceeded almost independently from one another and each of them in his own way. Kraepelin, who belonged to the school of Wundt, dealt first with certain theoretical questions, with which we are not concerned here. Ziehen made a special study of the results of the experiments with children. Sommer used the findings as an aid to psychiatric diagnostics.[8] This summary shows the manifold aspects of this simple experiment. As every layman would imagine, the possibilities of reaction to stimulus-words are apparently innumerable. It was therefore a great achievement to be able to prove that certain restricting laws are in operation.

[731] This proof is the result of the excellent study by Aschaffenburg,[9] a pupil of Kraepelin. He was able to show by means of experiments, as interesting as they were laborious, that mental and physical fatigue exert a definite influence on associations, as can be clearly demonstrated by statistics. It became apparent that under the influence of fatigue there was in particular an increase in what are called *sound associations*[10] (e.g., *dish / fish, red / bread, wood / good*). Aschaffenburg took this important fact as a starting-point, and he then showed that similar associations occurred in a mental disease, namely in *mania*. The question of the common psychological cause of the same phenomenon in these heterogeneous psychic states remained for the time being obscure. In

1901 Bleuler inaugurated research into associations at the Psychiatric Clinic in Zurich. These investigations led in 1904 to the discovery that sound associations are due to disturbances in attention.[11] A second result was that the content of the reactions was not *merely coincidental* but *inevitable;* i.e., what came into the minds of the subjects was not meaningless and incidental material but was determined according to a law by the individual content of the subject's ideas. This may be illustrated by the following example.

[732] One of my subjects was a young man who had had an unpleasant dispute with his family a short time before the experiment. He wanted to marry a girl of whom his parents did not approve. As an obedient son he had to give her up, hard though it was for him. These events dominated his interests at the time of the experiment. It is therefore not surprising that numerous reactions were influenced by the recollection of this experience, as the examples show.

Stimulus-word	*Reaction*
to kiss	again and again
bad	no
time	not now
mature	am I
to love	ah!
son	father and son
wild	mother (wild=furious)
tears	she now has
protection	I cannot offer to her
war	yes, if only there were
faith	I did not keep
once	and never again
miracle	would have to happen
blood	she is anaemic
choose	another one
to part	I need not
right	she has none
fond	I was, of her
wool	a woman's dress

unfair	I was not
stranger	yes, now she is

[733] On rereading these reactions it can be seen at once that their contents are not meaningless and that these are not random choices out of the thousands of possible reactions, but just those that indicate the ideas occupying the foreground of the individual interest. It is, as already mentioned, the story of an unhappy love-affair. Such a recollection, which is composed of a large number of component ideas, is called a *complex of ideas*. The cement that holds the complex together is the *feeling-tone* common to all the individual ideas, in this case unhappiness. We are therefore speaking of a *feeling-toned complex of ideas*,[12] or simply of a *complex*. In our case the complex has the effect that the subject does not react by arbitrary or random connections of words but derives most of his reactions from the complex. The influence of the complex on thinking and behaviour is called a *constellation*.[13]

[734] The reactions of our subject are thus *constellated by a complex*.

[735] Does this behaviour work according to a law, and are the reactions in all subjects constellated by complexes?

[736] There is no one who has no complexes, just as there is no one who is without emotions. Yet human beings differ immensely in the strength of their emotions. In accordance with the intensity of their emotions people's thinking and behaviour are constellated by their complexes, and so are their associations. One is bound to ask, with some surprise, whether revealing or concealing one's complexes is not a matter for individual decision. By no means everyone will disclose his secrets so openly and without embarrassment as this young man did. True, this young man was an exception; he had confidence in the experimenter and said everything just as it came into his head. By no means everyone behaves like this; on the contrary, many are strictly on their guard not to say anything that might be compromising. Others are more casual and just fit one word to another without thinking of any deeper connections. Does a complex constellate the association even in a case where one is not thinking of anything in particular and certainly not of one's secrets? Theoretically, the question has definitely to be answered in the

affirmative, because nobody can do anything that is impersonal; there is certainly no psychic manifestation that has not an individual character. Practically, however, it is not so easy to answer the following question: Is it also possible to demonstrate the constellation by complexes in associations in which the subject either does not want to give himself away or is not thinking of anything in particular?[14]

[737] In spite of having formulated the appropriate questions, psychology has up to now been unable to prove anything of individual significance in the associations. It was our experiments that first succeeded in finding the approach to this goal.

[738] As already mentioned, not every subject reacts as openly as the case described above; as a rule the associations are at first sight quite impenetrable and sound impersonal and safe, like those that follow here.

to dance	not
ill	not
angry	friendly
needle	nail
rich	rather
tree	branches
to sing	beautiful
pity	not at all
detest	rascals
people	religion
stink	abominable
unfair	atrocious

[739] These associations appear to have an impersonal character and are thus very different from those quoted earlier. This might therefore lead to the assumption that they are nothing but casual, entirely incidental word-connections. On questioning the subject, however, we learn that this is by no means the case. It is not accidental that the subject responds to *to dance* with *not*, but it corresponds to a quite special individual situation. The man who was my subject could not dance, a fact that annoyed him, particularly because a friend was very good at dancing and thus won the love of a very “eligible” girl. My subject also wanted to marry an

“eligible” girl, but did not succeed, and this angered him even more than not being able to dance. It worried him so much that he nearly became *ill* with it, but he did *not* really become ill in spite of his despair. The girl is *rather rich*. He does *not at all* deserve any *pity* for his lack of success because everybody has to work for his fortune. And because the lady who turned him down was Jewish, he came to *detest* the rascals (i.e., the Jews). Since the Jewish *people* have a different *religion* from his, the problem of religion is of course also particularly important for him. Towards the end his anger breaks through more plainly with the expostulations *abominable* and *atrocious*.

[740] Thus here too we find the complex and its constellation quite distinct. Up to now we have relied entirely on the statements of the subject. But now let us look more closely into the contents of the reactions.

[741] It is definitely striking that the reactions to *to dance* and *ill* are *not*, just as remarkable as that the subject says *rascals* in answer to *detest,* and *not at all* to *pity*. Surely one could at these points think of much more innocent and objective connections which seem to be nearer at hand, e.g.,

to dance	music, dance-hall, ball, etc.
ill	disease, doctor, etc.
detest	respect, contempt, etc.
pity	for the poor, the sick, or compassion, etc.

[742] The unusual content of the reaction therefore already allows us to infer a constellation by complex. So it is, for instance, striking if an elegant young man reacts to *goat, potato, cow*, each time by *agriculture*. The explanation is that he is a student of *agriculture* in his first term. I could easily pile up examples, but this is not necessary; for even without them it is feasible to conclude from the unusual content of a reaction that there is a constellating complex. This can be done even without getting information from the subject afterwards. If, for instance, a marriageable girl responds to *to kiss* with *sister’s kiss*, it is not difficult to guess what is meant by that.

[743] But this does not exhaust the possibilities of suspecting and proving the influence of a complex, even without later information. Besides the

content of the reaction, we have another very fine criterion for the complex-constellation; this is the *reaction-time*. We always measure the time elapsing between pronouncing the stimulus-word and the reaction with a ⅕-second stopwatch. As might be expected, these times vary in an apparently random fashion. Closer inspection, however, soon shows that very long reaction-times nearly always occur in quite definite places. The following example shows which are the critical spots:

		(*secs.*)
head	hair	1.4
green	lawn	1.6
water	*deep*	5.0
to stab	knife	1.6
long	table	1.2
ship	*sinking*	3.4
to ask	to reply	1.6
wool	to knit	1.6
sulky	friendly	1.4
lake	*water*	4.0
ill	healthy	1.8
ink	black	1.2
to swim	*to be able to*	3.8

[744] In this example most of the figures vary between 1.2 and 1.8 seconds. But besides these there are four unusually long times, ranging from 3.4 to 5.0 seconds. If we ask the subject now why he hesitates at these points, we learn that once in a moment of despair he had seriously contemplated suicide by drowning. The stimulus-words *water, ship, lake,* and *to swim* stimulated this complex. During the short interval between stimulus-word and reaction something unpleasant (the complex) had crossed the subject’s mind, and the result was a slight hesitation. The same phenomenon is noticeable in everyday conversation when we ask someone something that is unpleasant either to us or to the other person; we dither a little and hesitate over the question or with the answer. The hesitation here is quite involuntary and a kind of reflex. It is noteworthy that the same hesitation also occurs at the moment of the reaction, when we are quite unaware of the complex-releasing effect of the stimulus-

word. Hundreds of cases have taught us this. From this we see that the stimulus-word can also release complexes of which we are not aware at the moment, which may even be separated from consciousness by amnesia, such as is very often the case in hysteria. By measuring the reaction-times we therefore have another means of detecting complex-constellations, even without co-operation from the subject.

[745] There is also a third method of finding a complex, which is called the *reproduction method*.[15]

[746] We usually record a series of a hundred responses from the subject whose complex we wish to investigate. When this series is complete, we ask the subject to repeat his reaction to every single stimulus-word. Here memory often fails. Then we go into the question of whether the points where incorrect or incomplete reproductions are given are random or determined. For the sake of simplicity we give here the previous example again.

stimulus-word	*reaction*	*reproduction* [16]
head	hair	+
green	lawn	+
water	*deep*	*to swim*
to stab	knife	+
long	table	+
ship	*sinking*	*steamer*
to ask	to reply	+
wool	to knit	+
sulky	friendly	+
lake	*water*	*blue*
ill	healthy	+
ink	black	+
to swim	*to be able to*	*water*

[747] The reproduction fails for *water, ship, lake,* and to *swim,* i.e., for the same stimulus-words for which long reaction-times had originally been recorded. This shows that memory fails in the places where there is a complex in operation. We do not want to deal here with the interesting

theory concerning these disturbances; this has already been done in the paper mentioned above. It should merely be remembered that memory is seriously deranged by an affect, as nobody knows better than an examining magistrate. Let us summarize briefly: We can demonstrate the complex-constellation objectively by the unusual or in any way striking content of the reaction, by the prolongation of the reaction-time, and by incorrect reproduction.

[748] If we apply these three criteria to the associations, we soon find, however, that the matter is not as simple as it looks, because we see that, though these criteria apply to certain associations, they make no sense at all in, for instance, the following cases:

to stab	knife	1.6	+
angel	pure	1.2	+
long	trunk	2.8	tree
ship	man	1.2	+
to plough	field	1.4	+
wool	sheep	1.6	+
friendly	lovely	1.6	+
table	leg	4.0	chair
to ask	answer	1.6	+
the State	form (shape)	6.2	Switzerland
white	black	1.2	+
pencil	pen	1.0	+
lovable	dear	1.4	+
glass	to love	4.6	to drink

[749] If we apply our three criteria to these associations we find *long, table, the State, glass* to be the critical stimulus-words. This grouping does not tell us anything and does not lead to any hypothesis. But could it not be that the complex is not yet fully aroused by the stimulus-word, but makes its appearances only with the reaction? In this case the reaction following the critical reaction would be mainly affected. Let us apply this to our example and consider the stimulus-words preceding the apparently critical reactions. They are *angel, friendly, to ask, lovable*.

[750] Whereas we had questioned the subject, a young man, on the previous stimulus-words in vain, his face brightened up when we offered him the new ones. He had just become secretly engaged; the beloved had answered his question with a friendly “yes.” In this case, therefore, the post-critical reaction is also constellated by the complex. This very common process is called *perseveration*. That perseveration can also strongly influence the contents of a reaction is shown by the example:

[751] I have chosen a rather simple example to demonstrate what is from the practical point of view an important variety of the complex-constellations. As a rule the situation is much more complicated, inasmuch as all the possible factors are present together. In people whose emotions are easily roused (hysterics) the complex-constellation can even extend over a whole series of ensuing reactions. A hysterical female patient who had attempted suicide, for instance, reacted as follows:

1. water	(failure)[17]	−	+
2. to sting	bee	1.8	+
3. angel	inn	21.0	(did not react at all, as after *water*)
4. long	knife	9.0	(as 3)
5. ship	steam	7.0	(as 3)
6. to plough	field	4.2	garden

[752] From the seventh reaction on there were again normal reaction-times and correct reproductions. In this example we can observe various features. The subject does not know in the least how to react to *water*. The reaction-time extends as it were to infinity. Ultimately, of course, she would come to some sort of a reaction, but to a forced one, which is of no use. We therefore never wait longer than about 30 seconds. What prevented the patient from reacting was the unpleasant recollection of the suicide attempt which cropped up here. In *angel / inn* the reaction-time is extremely long, because *angel* reminds her at once of the suicide attempt again, of dying and the next world, and this time with such an intensity

that the emotional tone of the complex lasts over the next three reactions. The gradual subsiding of the emotional tone from reaction 3 on can clearly be seen in the reaction-times.

[753] We have discussed here the most important disturbances that the complex produces in association and reproduction, and have now to deal with the question of how much of these theoretical findings can profitably be used for practical purposes.

[754] In the first place, we have gained with this experiment a most valuable tool for psychology. With it we can demonstrate the existence of certain complexes of individual significance for our subjects, a fact that is bound to become of great theoretical importance. Secondly, the experiment is important for psychiatric practice in that, especially in hysteria, in which as a rule the whole mental life is disturbed, it provides us with the most valuable indications for finding the pathogenic factor, since in hysteria a complex is always at work.[18] The experiment serves us equally well in the elucidation of another mental disorder, *dementia praecox*.

[755] The latest application of our experiment was suggested by Wertheimer and Klein,[19] two pupils of the well-known criminal psychologist Hans Gross. This is its application to the delinquent—the exploration of the complex underlying a crime. Just as any subject who submits to the experiment unconsciously gives himself away, as we have shown, so the criminal, who has knowledge of certain facts, is bound to do the same. This, it is hoped, will make it possible to prove by experiment whether or not a person has any knowledge of certain facts. As everyone will appreciate, this question is of enormous practical importance.

[756] While the paper by Wertheimer and Klein mentioned above made only general suggestions about this, Wertheimer has dealt in another paper[20] with relevant experiments carried out in Külpe’s laboratory at Würzburg. The experiment was set up as follows.

[757] The subject was shown a picture, the contents of which he had to commit to memory (e.g., a picture of a religious service in the chapel of a

crypt). The stimulus-words were in some cases chosen from the picture (names of objects shown or otherwise obvious associations with it), but in other cases irrelevant words with no recognizable relation to the picture were used. These stimulus-words were called out to a number of subjects. The reaction-times were recorded with exact instruments (megaphone and chronoscope). The subjects had previously been instructed not to give themselves away, i.e., not to give any associations revealing that they had seen the picture. The results are in keeping with our previous exposition. The stimulus-words arousing the complex (relating to the picture) yielded an unusually large number of *long* reaction-times, and in these cases the reactions also gave a strange impression; there was something deliberate about them. It also often happened that the complex-characteristics appeared in reactions to irrelevant stimulus-words. In these cases a stimulus-word relating to the complex had appeared immediately before. Wertheimer was also able to confirm that the more emotional involvement there was, the more marked were the reaction-times and the qualitative and perseverative phenomena.

[758] Since the Wertheimer-Klein publication similar experiments which provided similar results have been carried out by Hans Gross[21] and by Dr. Alfred Gross[22] of Prague. What underlay these experiments was the knowledge or lack of knowledge of a certain room and its furniture. Alfred Gross has discussed very clearly the general aspect of the problem,[23] especially with regard to its juridical application.

[759] I should like to mention first, among the critical comments, that by William Stern:

> The problem is certainly very interesting from a purely psychological point of view, and the suggested procedure is to be welcomed as a remarkable extension of our methods of approach, but it seems to me that there is a powerful objection to the practical forensic application of the method. In court there is no really sharp distinction between those people in whose minds the facts of the case are present and those in whom they are completely absent, since nearly everyone who has to do with a case in a law court, whether as the defendant or as a witness, knows either what he is accused of or why he is being interrogated, no matter whether he

was actually in any way involved. Even the mind of someone falsely accused is, from the very first examination by the magistrate, continuously burdened with ideas concerning the matter. Every suggestion must call to consciousness the ideas with which he is preoccupied, just as if he were guilty, and must also evoke emotional reactions which in their manifestations, even as part of an experiment, can hardly be distinguished from those of guilt; it is well known that blushing, which so often occurs as a result of baseless accusations, has before now been interpreted as a symptom of guilt. Is there not a similar great danger in the psychological experiments suggested by Wertheimer and Klein?[24]

[760] I feel obliged to support this objection fully, and should in particular like to stress that the innocent as well as the guilty has the greatest interest in reacting so as to show to the best advantage. The guilty man is afraid to give himself away, and the innocent to put himself in the wrong, by reacting in an awkward manner. The critical reactions will therefore in both cases be accompanied by strong emotional tone, which interferes in a characteristic way with the associations. This might make it difficult to distinguish between guilty and innocent. We shall come back to this question in more detail in the second part of the paper.

[761] In a recent publication Stern discussed my paper "The Reaction-time Ratio in the Association Experiment," in which I gave a detailed analysis of the experiment. Stern considers it of doubtful value to let the subjects explain the associations afterwards, as I made them do. I am ready to admit that the method is in any case difficult and dangerous. For this reason I chose as subjects for the analysis three people whose life and psychological make-up were known to me, and who were themselves psychologically experienced, especially in the observation of association. One could not ask everyone for an explanation of his associations, because they are not casual things but the most intimate and affective ones, on which even an honest self-criticism may fail to function. A certain special experience in the experimenter and also a fair knowledge of certain aspects of psychopathology are necessary with subjects who are not used to psychological experiments. These are the principles of Sigmund Freud's ingenious psychoanalysis.[25] Only when one has

completely assimilated Freud's method is one able with any certainty to consider associations from a psychoanalytical point of view. It has to be conceded to Stern that an inexperienced experimenter can easily make the gravest mistakes with this delicate material. In any case, even Freud has been accused of interpreting into a subject's statement more than is in it. To this reproach, however, it must be said that very likely everyone would respond with a canalized association rather than a spontaneously created association when asked what comes to mind in connection with a certain idea; this, of course, applies also to any retrospective elucidation.

[762] In his discussion of Wertheimer's suggestion Kraus[26] puts forward the idea that the method has not been sufficiently tried out. I would draw Kraus's attention to the fact that a number of papers were published from the Psychiatric Clinic of Zurich University which discuss the method in considerable detail.[27] That the method lends itself to the discovery of complexes seems to me beyond doubt. When it comes, however, to applying the method to someone giving evidence, one cannot be too careful. Therefore I agree with Kraus when he foresees great difficulties in applying the experiment in judicial procedure.

[763] Kraus continues: "But I must ask, can the examiner claim the right to base any judgment on the inextricably entangled web of my associations?"

[764] The author may forgive me if behind this question I suspect insufficient appreciation of the problem of association. A careful study of the existing literature would have taught him that the "web of the associations" is precisely not "inextricably entangled." If it were we should be at our wit's end, and we could refrain *a priori* from searching for laws among the infinite number of chance events. The experiment is simply based on the fact that there actually are laws determining the possibilities which *more and more* exclude the unaccountable.

[765] If we know these laws, then we also know the intimate association-processes of the subject, whether he likes it or not. Kraus thinks one would have for that purpose to have "that rare gift for psychoanalysis of which Freud brings amazing evidence in his remarkable papers." Freud is certainly a man of genius, but his psychoanalysis is, in its principles at

least, not an inimitable art, but a transferable and teachable method, the practice of which is greatly helped by the association experiment, as can perhaps be seen from the papers published from our Clinic.[28]

[766] I repeat what I have already said elsewhere: The truth of this experiment is not obvious, it has to be tested; only someone who has used it repeatedly can judge it. Modern science should no longer recognize judgment *ex cathedra*. Everybody derided and criticized Freud's psychoanalysis,[29] because they had neither applied nor even understood the method, and yet it ranks among the greatest achievements of modern psychology.

[767] Weygandt,[30] too, thinks that there is still a long way to go before it will be possible to use the method in forensic procedure. He also thinks it desirable that the experiments should continue, especially with uneducated subjects. Weygandt further draws attention to the fact that the criminal probably does not observe the scene of the crime so closely that stimulus-words for the tests can simply be taken from the objects situated there. It is also likely that the emotional tone necessary for interfering with the association is precisely what the habitual criminal lacks.

[768] These objections must be unreservedly acknowledged.

II

[769] The practical application of the association method is best illustrated by a case on which I was consulted in my capacity as a doctor. Here is the history of the case.[31]

[770] One evening in September 1905 an elderly gentleman came to see me. He was evidently agitated and asked for a consultation on an important matter. He told me that he lived with a young man of eighteen, his protégé. For several weeks he had noticed that on a number of occasions larger or smaller amounts of money had been missing from the strongbox. Although he was somewhat absent-minded and not particularly careful in money matters, he was quite sure that there was a deficit of at least 100 francs. He reported the matter at once to the police, but there was no evidence at all against anyone. Recently there had been some changes among the servants; it was thus possible that one of the

maids had taken the money. Now it had also occurred to him that his protégé might have stolen from him. If he knew that the young man was the thief, he would do whatever he could to prevent the police getting to know of it; in that case he would rather deal quietly with it himself in order to avoid embarrassment for the family of his protégé, who were highly respectable. For the purpose of coming to a decision in this awkward dilemma he wanted me to hypnotize the young man and question him, while under hypnosis, as to whether he was the culprit or not. I rejected this suggestion because such an undertaking is not only technically most difficult but also fruitless. But I suggested the association experiment. Fortunately the young man had intended once before to consult me because of some minor nervous complaints. Thus the guardian was able to send him to me under the pretext of a consultation. Before long the young man turned up and consented to the experiment.

Experimental Procedure

[771] In order to stimulate the complex as strongly as possible, I prepared a sheet of stimulus-words in which I distributed thirty-seven words relevant to the possible facts of the matter. The guardian had informed me that the money was always kept hidden in a drawer amongst shirts and ties beneath a small board. The drawer was in a chest and was kept locked. It was possible that it had been opened with a master key. In the same room there was also a trunk in which money was occasionally kept. A linen-cupboard also stood near the chest of drawers. The suspect youth had recently bought a watch and given some small presents to his sister. He might have got the money from the theft; his guardian, however, did not know, because he hardly ever bothered about his protégé’s finances. There were no other significant features in the room where the thefts had taken place. As critical stimulus-words I chose: *to give a present, watch, to give, drawer, sister, burglary, writing case, sin,*[32] *to threaten, key, to steal, board, to look for, to lock up, master key, to hide, thief, to find, wrong, shirt, to watch, tie, trunk, to hit, to catch, police, to moan [accuse],*[33] *chest of drawers, arm [poor],*[34] *to arrest, jail, false,*[35] *anxiety, linen-cupboard, to punish, month,*[36] *criminal*. These thirty-seven

stimulus-words touching the complex were distributed amongst sixty-three “irrelevant” stimulus-words, special care having been taken so that an irrelevant stimulus-word was frequently put immediately following a critical one. This was done because of the fact that the emotional charge often perseverates into the post-critical reaction. In this way it could be hoped that the complex-constellation would emerge fairly clearly. I am now going to describe the experiment as it took place. Between the sections I shall insert explanatory remarks. At the end I shall give a statistical survey to bring the experiment to life. The association experiment was complemented by a reproduction test.

[772] I should like to point out that the probable mean[37] of the reaction-times in this case, in which the subject belongs to the educated class, is 2.0 seconds. Excessively long reaction-times therefore are those above 2.0.

1. head	nose	2.0	+
2. green	blue	1.2	+
3. water	air	1.6	blue
4. to stab	painful	2.0	+
5. murder	manslaughter	1.4	+
6. long	short	1.8	+
7. five	six	1.4	+

These reaction-times show no peculiarities as yet, though one might perhaps mention the incorrect reproduction for *water* as suspect, suggesting a complex-constellation. It is, of course, impossible to explain every minute complex-interference by means of an obviously incomplete analysis carried out in retrospect, as in this case.

8. *to give a present*[38]	gen-*generous*[39]	2.0	to give
9. wool	cloth	1.4	+

The reaction to the first complex-stimulus-word fulfils the above criteria for interference by the influence of a complex. The reaction itself is characterized by a slip of the tongue. The reaction-time is not short and the reproduction is incorrect. No after-affect on the following association.

10. *watch*	mechanism	2.2	+
11. table	leg	1.8	wood

The second complex-stimulus-word *watch* produces a foreign word[40] as a reaction, which is somewhat unusual. The reaction-time is excessive.[41] The post-critical reaction is incorrectly reproduced, so that a perseverating emotional charge may be suspected.

12. *to give*	*to steal*	2.6	+
13. chair	-leg	2.0	+
14. sulky	morose	2.8	+

In 12, the complex is openly expressed with an excessive reaction-time. The post-critical reaction-times are rather long. The reproduction is not disturbed.

15. *drawer*	wood	1.6	+
16. *sister*	brother	1.8	+
17. lake	water	1.4	+
18. ill	well	2.0	_[42]

Here no obvious complex-influence on the two critical stimulus-words is apparent. The missing reproduction for *ill* may be due to something other than the theft-complex.

19. *burglary*	*theft*	1.8	+
20. to cook	−	−	−
21. ink	paper	2.6	+

Here we have all the criteria of the complex-constellation. The perseveration was so strong that it led to a failure, an absence of the post-critical reaction. The reaction-time for 21 is still very long.

22. evil	good	2.0	+
23. *writing-case*	paper	2.0	+
24. to swim	good—don’t know	2.0	freely, doing well

The critical stimulus-word interfered again with the post-critical reaction and its reproduction by means of a perseverating emotional charge.

25. *sin*	disgrace	1.8	+
26. blue	black	1.4	+

27. bread	water	1.6	+
28. *to threaten*	−	−	−
29. *key*	lo-hole	2.6	+
30. rich	poor	1.2	+

Sin obviously did not, or not appreciably, arouse the complex. *To threaten*, however, is followed by the failure to react characteristic of emotion and by lack of reproduction. This powerful effect of the stimulus-word may perhaps also be ascribed to the fact that 27 already contains the expression of a complex-constellation: bread and water = jail. In 29 the disturbance is very obvious; the reaction is disturbed by a slip of the tongue, and the reaction-time is excessive.

31. tree	green	1.2	+
32. *to steal*	*to take*	2.4	+
33. *board*	wood	2.8	+
34. yellow	black	2.2	+

To take does not contradict the complex. I do not know whether the long reaction-time following *board* stems from this complex-word or by perseveration from *to steal*. The reaction-time after *yellow* is, however, still excessive, which might indicate some slight perseveration from *board*.

35. mountain	high	1.8	+
36. *to look for*	*to find*	1.6	+
37. salt	−	−	+
38. new	old	2.0	+

The characteristic perseveration, with inhibition of the following reaction, originates with *to look for. To find* does not contradict the complex; on the contrary.

39. *to lock up*	*to imprison*	2.6	to release
40. to ride	river	2.0	+

The critical stimulus-word distinctly influences not only the expression of the complex, but also leads to a mishearing of the subsequent stimulus-word; as shown also in the reproduction (*riding: reiten* = Rhein).

Mishearing of the stimulus-word is a not infrequent phenomenon in a complex-constellation.

41. *master key*	*key*	1.6	+
42. stupid	intelligent	3.0	+

Key, as an associative response to the complex, must not, of course, be overvalued. The prolonged reaction-time in R.42 is more telling.

43. exercise-book	book	1.8	+
44. *to hide*	*to find*	2.0	+
45. tooth	painful	1.4	+

To find is a frequent association to *to hide*, so it must not be too highly valued as a complex-association. It looks as if *to hide* has only just touched the complex. The response to *to look for* was also *to find* (36). Such comparisons are useful, even if they do not reveal very much. Occasionally, however, they are valuable if one is trying to detect an unknown complex.

46. right	false	2.2	+
47. *thief*	*burglar*	4.6	criminal
48. *to find*	*to steal*	2.6	to look for
49. book	−	−	statute-book

With *thief*, serious complex-disturbances set in which I need not elaborate.

50. *wrong*	right	1.2	+
51. frog	water	2.2	tadpole
52. to separate	tadpole	2.6	+

Strong perseveration appears to be connected with *wrong*. But it is more likely that this disturbed sequence is still under the influence of R.47ff, as can often be seen in strong emotion. If one watches the subject during the experiment, one can frequently see facial expressions at complex-points that at once reveal the strong emotional charge. This was the case here. From 47 on the subject became restless, gave embarrassed titters, moved his chair to and fro, rubbed his hands or hid them in his pockets. This shows that the disturbances in the associations, as well as other symptoms, are only expressions of the total effect.

53.hunger	thirst	1.4	+
54. *shirt*	white	2.0	cloth
55. *child*	small	1.8	+

Shirt seems to have made a hit.

56. *to watch*	*to miss*	1.8	*s-conceal*[42a]

The influence of the complex is here particularly obvious in the reproduction. The slip of the tongue *s* could be an anticipation of *conceal*, or should *s* have become *steal?*

57. *necktie*	cloth	1.6	+
58. dim	dark	1.6	+
59. *trunk*	to pack[43]		+
60. *to hit*	*to miss*	1.8	certain
61. statute	book	1.8	+
62. lovable	faithful	1.8	+
63. *to catch*	*to miss*	2.4	to get hold of
64.to quarrel	to love	3.4	–

From this series we see the part that *to miss* plays. It occurs only in response to complex-stimulus-words, when it is in each case incorrectly reproduced. It seems to be one of those cover-words that not infrequently appear in this experiment. What is hidden beneath it seems to be the thief’s fear of a surprise. The words relating to the locality of the incident, *tie*, *trunk*, appear to be of little influence.

65. *police*	*thief*	3.6	+
66. large	small	1.6	+
67. *to moan* [*accuse*]	to sigh	1.6	+
68. to paint	beautiful	3.8	+
69. *chest of drawers*[44]	comfortable	2.8	+
70. old	new	1.2	+

Police is a direct hit; *to moan* has its after-effect. *Chest of drawers* is translated [see n. 44] after a long reaction-time; the hit has thus been parried.

71. flower	heath	2.0	+
72. *arm* [*poor*]	leg	1.6	+
73. wardrobe	cupboard	2.0	+
74. wild	brook	2.0	+

75. family	*sister*	2.2	+
76. to wash	clean	1.8	+
77. cow	bull	1.8	+
78. strange	*to watch*	2,2	+

In this sequence *poor* (cause of the theft?) has no arousing effect. The choice of *sister*, however, for family, which had not been intended to be a complex-word, does not seem to be coincidence. *To watch* as an association to *strange* is odd; is there perhaps the faint thought behind it that someone must have watched and reported him, so that now even a stranger (myself) knows of the deed? Of course, the suspicion is not proof; one has, however, to keep such trains of thought in mind in the interpretation.

79. *to arrest*	*thief*	3.4	+
80. story-telling	fairy-tale	2.0	+
81. manners	custom	1.8	+
82. narrow	broad	1.8	+

To arrest was a direct hit; then there was a slowly declining charge (reaction-times!).

83. brother	*sister*	1.4	+
84. *jail*	*prison*	4.2	+
85. stork	child	2.2	+
86. *false* (cannot understand the stimulus-word at first, then)	*rich*	4.0	+

Rich is a peculiar reaction to *false;* if, however, a subject has stolen a considerable sum from his benefactor, then the response is no longer quite incomprehensible.

87. *anxiety*	*silly*	2.4	−
88. beer	wine	1.6	+

It was easy for the subject to persuade himself that his anxiety about giving himself away with the experiment was silly.

89. fire	shot	2.0	+
90. dirty	clean	1.4	+
91. door	trap-	1.6	+

92. *linen-cupboard*	wood	3.0	+
93. hay	grass	1.6	+

Linen-cupboard appears, to draw conclusions from the long reaction-time, not to be quite without meaning.

94. quiet	calm	2.0	+
95. mocking	irony	1.6	+
96. *to punish*	*to release*	2.4	+

An obvious complex-constellation.

97. *month*	week	1.8	+
98. coloured	green	6.2	+

Month, under the constellation of punishment, had obviously a strong affect.

99. *criminal*	*thief*	2.2	murderer
100. to talk	to be silent	2.6	to speak

[773] The total result of this experiment appeared so convincing to me that I told the subject point-blank that he was a thief. The young man who, up to now, had shown an embarrassed smiling face, turned suddenly pale and protested his innocence with great excitement. I then pointed out to him several points in the experiment that seemed to me particularly convincing. Thereupon he suddenly burst into tears and confessed.

[774] Thus the experiment was a complete success.

[775] This success, however, has to be examined critically. Above all, one has to keep in mind that the thief is not a hard-boiled habitual criminal but a sensitive young man who is also apparently tortured by his bad conscience (the complex). His complex had high emotional charges, which clearly affected the associations and in this way made the diagnosis of the theft possible. Had he had weaker emotional charges, the disturbances would also have been less, and the diagnosis would have been that much more difficult. Another circumstance that helped was that the culprit reacted in the manner of educated people, with single words and relatively short reaction-times. Had he been uneducated, or even somewhat mentally defective, he would have preferred to respond with

sentences or definitions, which are also always connected with rather long reaction-times. In this association-type[45] the subjects deliberate the reaction and formulate it as “suitably” as possible, which is apt to put the complex-constellations in the background.

[776] Not only the success of the method, however, but also the method itself has to be critically examined, inasmuch as we are not yet at all sure whether the critical stimulus-words cannot cause disturbances in innocent persons as well. The stimulus-words are partly such that even without a special complex they can arouse emotions or touch other complexes as well. There are also some words among them that are not in current use and that therefore have few ready connections in the language. Lastly, not all the rather long reaction-times are necessarily due to the influence of a complex, since they can just as well be caused by the rarity of the stimulus-word.[46]

[777] The rarity and complexity of the stimulus-words are, of course, also affect-arousing, in so far as they demand more attention. Many people also become inhibited because of the fear of appearing foolish, particularly uneducated women, who, in any case, get very easily embarrassed. It may therefore, *a priori*, be assumed that complex-characteristics may appear at moments when emotions have been aroused purely because of these difficulties. Then, a case is easily imaginable in which, by means of intended complex-stimulus-words, complex-symptoms are produced that are not, however, related to the suspected or expected complex but to a similar one that incidentally interferes with the one for which we are looking. Such a case can give rise to the most serious misinterpretations. Finally, disturbances can be produced by one group only of the complex-stimulus-words, so that one remains in doubt whether the subject is guilty or innocent. This can also occur if another complex interferes with the expected one.

[778] In the face of these difficulties it has to be plainly admitted that one hundred stimulus-words are definitely too small a sample to confirm beyond doubt the existence of a complex and to exclude the influence of interfering complexes. In our case, the attempt succeeded that one time because the situation was simple; another time, however, it could easily

fail. The obstacles that arise in these experiments are shown by the controls that I set up to check the list of stimulus-words specially chosen for the case of theft. [See pp. 344, 346.]

[779] I took as subjects two educated young men with whom I was closely acquainted. The one whom I am going to describe as the Informed knew the significance of the experiment carried out on him; the other was completely unaware of it. I am calling the latter the Uninvolved. The experiment was carried out on both of them in exactly the same way as on the Culprit. I must point out that for every subject one has always to think in terms of *his* probable mean-time.

Mean-time of:	*Secs.*
Culprit	2.0
Informed	1.4
Uninvolved	1.8

On the whole, the differences in these figures have an individual significance only.

[780] For the sake of brevity I have to restrict myself to discussing only the critical reactions, and just indicating the complexes of the controls.

8. *to give a present* passes smoothly for the Uninvolved; the post-critical reaction-time of the Informed is prolonged beyond the mean.

10. *watch* produces a failure in the Uninvolved, thus a complex-symptom. This subject is at present going through an unpleasant *waiting period* which seems to him to last very long (therefore the extended reaction-time for *long). Watch* arouses the same idea in him. The time for the Informed is also somewhat above the mean. The post-critical reactions are incorrectly reproduced by both controls as well as by the Culprit; therefore, the influence of a complex is likely. We can see that here all three of them are suspect. The analysis shows us, however, that for the Uninvolved the feeling-tone of the waiting time is very strong so that perseveration may be assumed. For the Informed, on the other hand, setting up house plays a prominent role at present: he has lately been intensely occupied with the question of furniture. The feeling-toned background for the furniture-complex is his fiancée.

	CULPRIT			INFORMED			UNINVOLVED		
Stimulus-Word	*Reaction*	*R-T*	*Rep.*	*Reaction*	*R-T*	*Rep.*	*Reaction*	*R-T*	*Rep.*

47. *thief*	*burglar*	4.6	criminal	*to steal*	1.4	+	*burglary*	1.6	+
48. *to find*	*to steal*	2.6	to look for	*to look for*	1.0	+	a find	2.4	to look for

* [Orig. *Zahn*/*zahm*, which gives a resemblance, and *wild*, 'wild', is the opposite of *zahm*, 'tame'.] † [In the sense of 'incorrect'.]

12. *to give* passes smoothly for the controls. For the Uninvolved, however, the post-critical reaction is disturbed. We learn that he depends on someone else's favour (*to give a present*) during this waiting period, which is very unpleasant for him.

15. *drawer* produces the reaction *chest of drawers* in the Uninvolved, which one might actually have expected from the Culprit. The association of *drawer* and *chest of drawers* just happens to be a very common association by contiguity which would not mean very much even for the Culprit. One could, however, easily be misled by it.

16-32. These sequences are very instructive. 16. *sister* releases the same response from all of them, but the Culprit has the longest reaction-time.

19. The reaction to *burglary* is very "suspicious," particularly in the Uninvolved. It is not known to me that he has ever stolen anything, nor

has he admitted any such offence. Even if he carried such guilt within him, his reaction is *de facto* worthless with regard to the complex in question, although the assumption would be tempting. The strong after-effect on the subsequent reaction is, however, absent in the controls.

23. *writing-case* produces disproportionately long reaction-times in the controls. Therefore the utmost caution is indicated here. The analysis could not trace the influence of a complex in the controls. Perhaps the “difficulty” of the word was mainly responsible.

25. *sin* hits the controls harder than it does the Culprit.

28. *to threaten* has a special effect on the Uninvolved, but not nearly as much as on the Culprit.

29. *key*. The reactions of the controls contain straightforward complex-words.

32. *to steal* reveals strong complex-influence in the controls. In the Informed it is a jocular reminiscence of the furniture-complex; in the Uninvolved the interference stems mainly from his reaction *to punish*, originating from the fact that he considers the loss of his job, which he had suffered, as a punishment.

	CULPRIT			INFORMED			UNINVOLVED

* [The German text misprints *Freund*, 'friend', here, though it gave *fremd*, 'strange', in the original list.]

With these examples it can be most impressively shown what unexpected difficulties the use of the test would have to face, even though it can theoretically be taken as certain that disturbances in associations are as a rule related to emotions and emotions to complexes; which complexes, however? This is the great question.

33. The strongest reaction to *board* is from the Culprit, although the contents of the reaction do not give anything away. The incorrect reproduction of the Uninvolved, however, is again disturbing. It is the result of the perseveration of R.32.

36. The most striking effect of *to look for* is on the Culprit (perseveration!).

39. *to lock up* produces very suspicious reactions. In the controls other complexes again interfere; in the Informed it is the furniture-complex, this time in obvious connection with the question of the money

needed for new furniture. For the Uninvolved it is again the complex about his unsatisfactory social position, which I cannot discuss here in greater detail. It is, however, remarkable that at this point the controls utter words indicative of complexes; the perseveration in the Uninvolved also corresponds to this.

41. *master key* acts in the same way, distinguishable from the Culprit's reaction only by lack of perseveration.

44. The action of *to hide* is also not distinguishable. There is interference by complexes in the controls as well.

47. *thief* has definitely the strongest effect on the Culprit, although the reactions of the controls are also complex-words.

48. Again, *to find* releases a feeling-toned reminiscence in the Uninvolved which confuses the result.

50. *wrong* and 54. *shirt* are uncertain.

56. *to watch* releases a complex (a love-affair) in the Uninvolved, thus distorting the result.

57. *necktie* and 59. *trunk* are uncertain.

60. *to hit* has the strongest effect on the Culprit.

63. *to catch out* and 65. *police* act in a very suspicious way, particularly in the Uninvolved; the complex of a secret love-affair interferes here.

67. *to moan* [*accuse*] is uncertain.

In 69. *chest of drawers*, the controls react with *drawer* and *furniture* more adequately than the Culprit with *comfortable*. Yet this reaction can easily be understood as a diversion, as a means of masking the complex. In strongly charged complexes, e.g., in hysteria, such diversions are the rule.

72. One might expect a similar result with *arm* [*poor*] / *leg*.

79. *to arrest* and 84. *jail* release the strongest reaction in the Culprit.

86. *false* and 87. *anxiety* act most strongly on the Culprit.

92. *linen-cupboard*, 96. *to punish*, and 97. *month* are uncertain. The Uninvolved has for *month* the complex of the waiting-period, hence the strong perseveration.

99. The effect of *criminal* is not clear.

[781] The result of the control-experiments is depressing: Obvious complex-symptoms can be seen at the critical points, not only in the Informed but remarkably often also in the Uninvolved, who really should have no theft symptoms at all. As it happened, however, he had two dominant complexes that could also be aroused by the stimulus-words pertaining to the theft complex. This brings home to us a fundamental weakness of the experiment: this is the multiplicity of meanings that the stimulus-words can have. One can hardly imagine how many associations, both concrete and symbolical, such words can arouse. Even for the sole purpose of narrowing the range of these possibilities, wide practical experience is required. We can come somewhat nearer to this goal by compiling as many stimulus-words as possible and by taking those that are as specialized as possible as critical stimuli. A test with only one hundred reactions is definitely inadequate.

[782] But, one is bound to ask with amazement, how could I dare to accuse the young man of the theft in view of such an uncertain state of affairs? Above all it must be stressed that, in addition to the practical test, there exists something that cannot be put on paper: namely those imponderables of human contact, those innumerable and immeasurable facial expressions which, to a large extent, we do not even consciously perceive, which affect only our unconscious, but which are most powerfully convincing. Apart from this indescribable quality that belongs to the experiment *in vivo* there is, however, some more tangible evidence that can be considered convincing: above all, there is the total result which, however, does not appear in the tables and which becomes obvious only by using statistical methods. Let us first consider the average of the reaction-times.

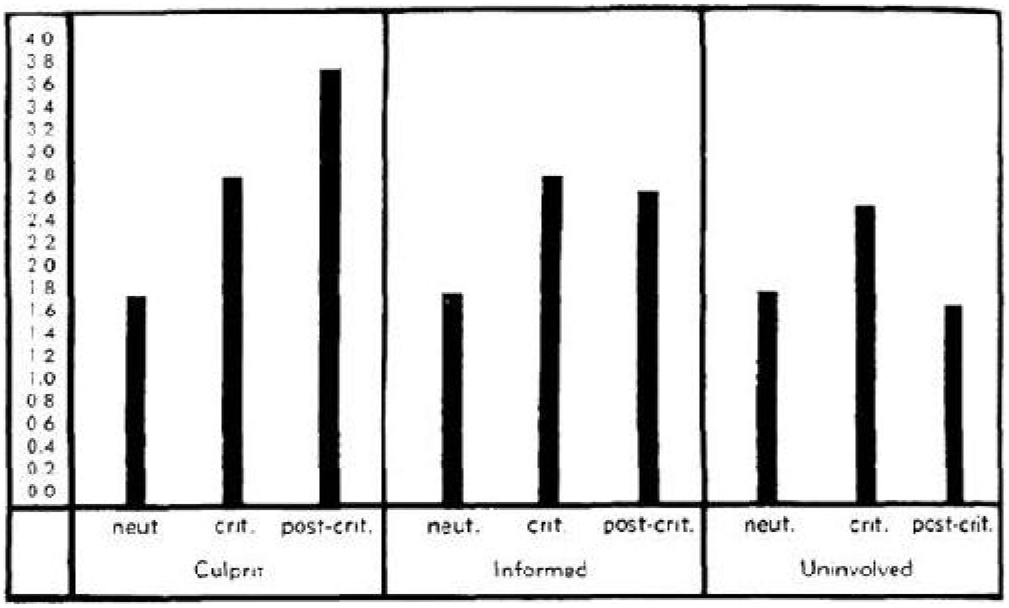
[783] For certain reasons, which I cannot enlarge on here, we take the arithmetical mean.[47]

Mean for …			
stimulus-words	*Culprit*	*Informed*	*Uninvolved*
neutral	1.9	1.0	1.9
critical	2.8	1.5	2.5
post-critical	3.8	1.4	1.8

[784] Reduced to the level of the mean value of the Culprit’s neutral reactions, the picture is as shown in Graph A (p. 350).

[785] From Graph A it can be seen that the Culprit is quite different from the controls in that his mean for post-critical reactions is excessively high and even greatly surpasses the mean of the critical reactions. That means, psychologically speaking, that the Culprit’s emotions during the critical reactions were much stronger than those of the controls and therefore perseverated with greater intensity. Although the critical mean value of the Informed nearly corresponds to that of the Culprit, the post-critical mean value falls below this level, just because in the Informed the emotions connected with the complex are missing. For him it is nothing but a complex of ideas concerning the experiment. This is even more obvious in the Uninvolved, for whom, as we have seen, the theft-complex is not in question and there is only a complex that occasionally interferes at the same stimulus-words. Actually, the critical mean of the Uninvolved should not have exceeded the neutral mean at all. That this does happen, however, stems from the fact that critical and post-critical stimulus-words together comprise not less than 65 per cent of all the stimulus-words. For this reason alone the critical stimulus-words are very likely to arouse the unconnected complexes.

[786] This graph also shows how the mere knowledge of the complex can compromise the result.[48] In spite of all difficulties, however, the graph shows considerable material indicting the Culprit.

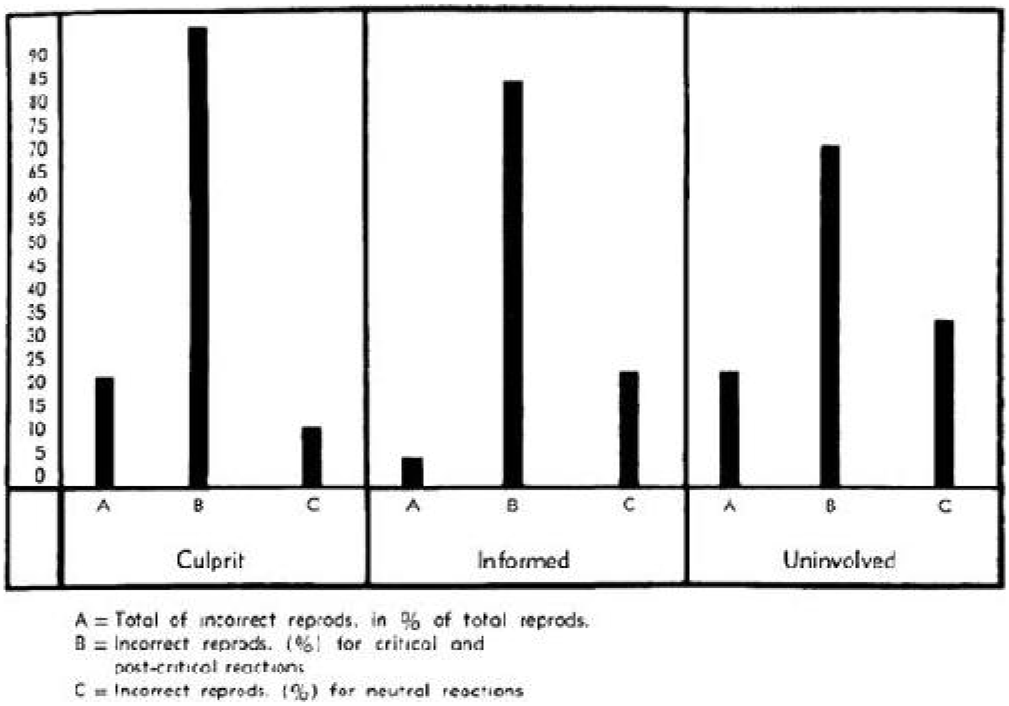


Graph A: Mean Values of Reaction-Times

[787] As we have seen, incorrect reproductions are also among the complex-symptoms. The Culprit reproduced 20 per cent of the reactions incorrectly, the Informed 5 per cent, the Uninvolved 21 per cent [see Graph B].

[788] As Graph B shows, the Culprit made mistakes in not less than 90 per cent of the reproductions of the critical and post-critical responses, the Informed in 80 per cent, and the Uninvolved in 71 per cent.

[789] Here again we see the strongest weight of evidence in the Culprit, although the figures for the controls are also unexpectedly high.



Graph B: Incorrect Reproductions

[790] The question of how often there are reactions to critical stimulus-words that may indicate the complex is an interesting one. According to Wertheimer’s data we could expect significant findings. Here we must take into account that any grouping from this point of view is extremely arbitrary. In the graphs I have always emphasized the critical reactions by the type. As can be seen, I have proceeded in a very generous way. This is one source of error: another is the fact mentioned above that the reaction may, contrary to expectation, conceal the complex instead of revealing it. For the Culprit, there are 49 per cent indications of complexes in critical and post-critical reactions, for the Informed 32 per cent, and for the Uninvolved 46 per cent. True, the figure for the Culprit is the highest, but this does not prove very much.

[791] The circumstance that the scene of the crime was somewhat commonplace presented a great difficulty in the experiment; it need not always be so. On the contrary, the scene could in another case be of such a special kind that there would inevitably be a large number of complex-stimulus-words which would appear harmless to the Uninvolved, while the Culprit would continually avoid complex-constellations; as our experience shows, that cannot happen without characteristic disturbances.

So much can already be seen from Gross's and Wertheimer's experiments.

[792] In summarizing, I must point out that the Culprit is distinguished only by the quantitative aspects of his complex-symptoms, and that this lends support to the diagnosis of the theft. Had the association method not become a most valuable diagnostic aid for psychopathology, making it possible to get access to pathological complexes, and had we not acquired a certain experience in carrying it out, I would not have ventured on that bold diagnosis. It was, however, the analogies with psychopathology that convinced me. I cannot therefore blame anyone who is not equally convinced. Far be it from me to dash cold water on the interesting and undoubtedly promising efforts and expectations of success in the psychological diagnosis of the criminal case; I am not sorry, however, with this case, to have been put in the position of giving a warning against undue optimism. I am giving it in the interest of this incomparably fine psychological method of investigation, which could easily be brought into discredit by drastic failures. The association method is a delicate tool which, up to now, is suitable for use only by experts, and one has on countless occasions to pay dearly for one's mistakes if one is not very experienced. Thus, as the method stands at present, one must not expect too much of it; it has, however, possibilities all of which can hardly be foreseen. The present article is meant not only as a warning but also as an encouragement to practise the association method, which is one of the most fruitful in all psychology.[49]

ASSOCIATION, DREAM, AND HYSTERICAL SYMPTOM[1]

I. THE ASSOCIATIONS

[793] I should like to support and clarify the views on the nature of anomalies of association in hysteria expressed in two others of these Studies[2] by presenting further investigations. The subject of this research is the following case:

A 24-year-old girl of fair intelligence and average education, physically healthy. The mother suffers from osteomalacia, which has completely crippled her. Otherwise nothing of hereditary relevance can be established. The patient is the youngest child, the only daughter, and has four elder brothers. Healthy up to school age. Very sensitive at school but made good progress. During the second year at school, twitching of the right arm began which soon made writing impossible; then the twitches became generalized until at last a hysterical chorea developed. The patient even became the focus of a small epidemic of chorea among the pupils. The chorea manifested itself in tic-like attacks, said to have lasted 1–2 minutes each. The patient threshed about and stamped, and occasionally screamed as well. There was no disturbance of consciousness during the attacks, which occurred 15–20 times a day. Menstruation set in at the age of 15 years. With the first period the attacks of chorea ceased quite suddenly (two years before this, the parents had consulted a specialist, who had said that the attacks would stop with menstruation). During the same week, however, dull sensations in the head set in, always towards evening. The sensations gradually assumed the character of heat, which got considerably worse during each period. The complaint increased with the years. At last the heat-sensations began at about 10 o'clock in the morning and gradually increased until they became unbearable. During the last three years the complaint became so bad that the patient was tortured by heat sensations in the head almost all day long. Innumerable attempts at cure by every conceivable method had no success at all. In the morning the patient was occasionally still able to help a little with the housework. From 10 o’clock on she walked restlessly about, persistently complaining about her head. Gradually she became afraid of other people and shunned all social contacts. During the summer she spent the hot weather in the cellar. In the winter she could not stand a heated room. Patient consulted me during the summer of 1905. This was followed by rapid deterioration. She was afraid of going mad, and had hallucinations of white and black figures at night. Was incessantly trying to be admitted to this institution. Was admitted in the autumn of 1905.

Condition: Well-nourished, graceful person. Expression of suffering which appears to be aimed at arousing sympathy; listless behaviour without any energy at all, which is also expressed by a spidery, sloping handwriting. Incessantly complains of heat sensations in the head. Complaints uttered in a whining tone of voice. The patient describes her sensations as follows: “My whole head is blocked up to the neck and quite hot, I must have a temperature of 104° in the head, it is quite tense as if choking; my throat is hot, dry, and parched, and I feel strangled. The feeling of dryness and heat at the back of my throat is terrible. It is always worse after a meal. At the same time my body is quite cold, my hands blue, my feet like ice. It seems to me if I could only once bleed properly from the *nose* I would feel easier. I keep imagining myself *bleeding from the nose and mouth*, a whole wash-basin full; I keep imagining *big clots of blood. I am also always dreaming of blood*. Often I dream I am wading in blood, the whole room is full of blood or *blood is gushing out of my nose, mouth, eyes, and ears*. Just as often I dream of *fire;* then everything is *ablaze.”*

When going off to sleep she often imagines she sees a black man who stretches his black hand towards her and clutches her arm. Occasionally she also dimly sees white female apparitions.

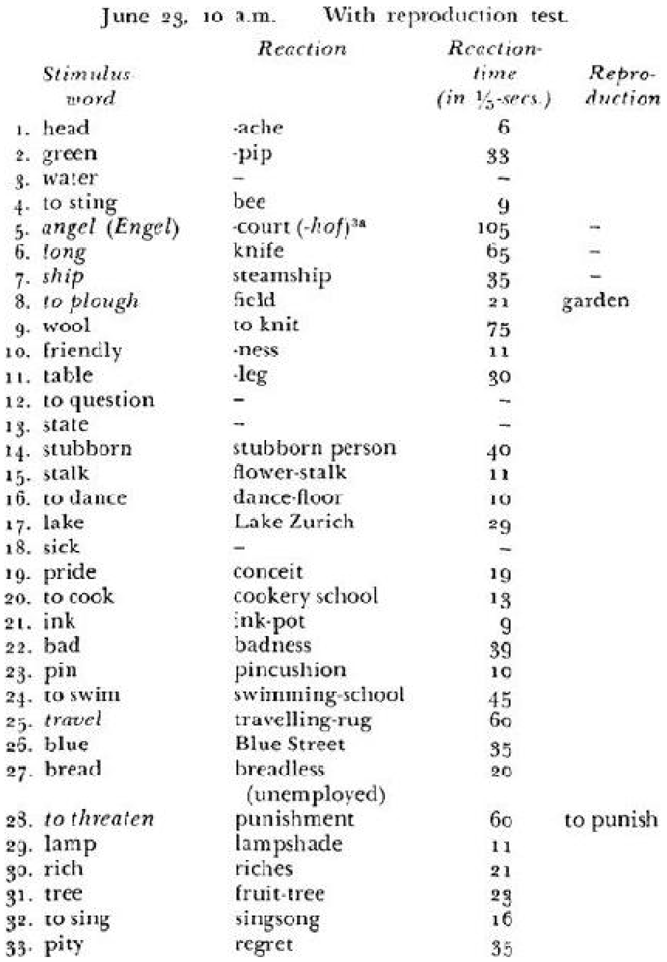
Since January 1905 menstruation has ceased, there is severe constipation; flatulence, alleged to have persisted for several months, which makes the abdomen protrude noticeably. The patient finds sitting unbearable, therefore remains standing or walks up and down the room. Profound loathing of meat, avoids everything that makes her hot. She has only to hear steam being let into the radiators and she feels worse. She washes in cold water several times a day and practises gymnastics in her room. These activities are very important for her. In a strange contrast to this are her aversion and dread of regular work, which she thinks is very bad for her condition. She shows a pathological love of orderliness and cleanliness (formerly, she says, she had for a time a compulsion to touch, so much so that she constantly had to touch all the objects in the room while walking about). The patient has no insight at all into the psychological nature of her complaint but is firmly convinced of an organic change in the head; she cannot, however, help laughing when explaining that one of her doctors took her for a case of Graves's disease. She has, of course, no idea of the causes of her illness, as little as the doctors who had hitherto treated her.

[794] There can hardly be any doubt that this is a case of hysteria. The long duration of the illness and the lack of alteration in the syndrome, not quite usual in hysteria—i.e., the unchanging character of the main symptoms—point to a deep-seated paralysis of psychic energy and a complete subjugation of the personality by the illness. The patient has been ill for seventeen years. In considering the peculiarity of the case one must take into account the fact that there has been a continuous development from the "St. Vitus's dance" (choreatic tic) into the present condition. It cannot be assumed that the chorea was cured, but everything speaks for the fact that under the influence of the first period it was simply replaced by another manifestation of the basic illness. Her completely childish and asthenic personality shows all the characteristics of the infantile Meige-Feindel tic.[3]

[795] For the sake of clarity I am now going to describe the association experiments that I carried out with the patient. The patient had treatment from October 1, 1905, to December 21, 1905. The experiments were made during this period. The treatment resulted in a certain success, which had considerable influence on the experiment. The tests were carried out each time in a room that had been only moderately heated (13°C. = 55.4°F.), because the patient could not stand more than about 11°C. = 51°F. for any length of time.

THE ASSOCIATION TESTS

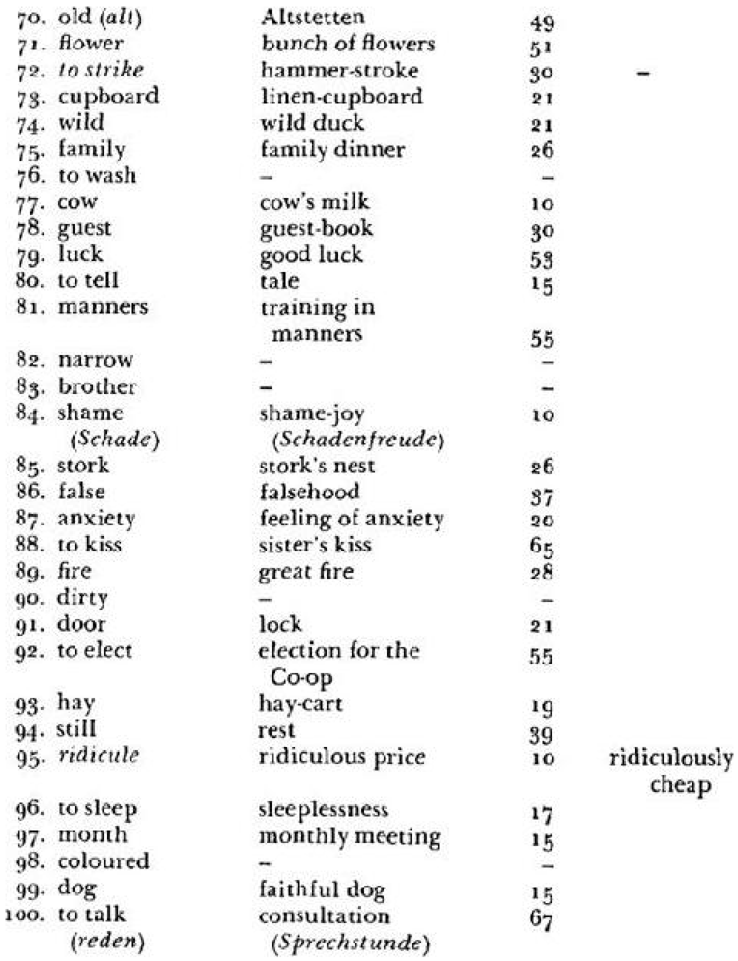
Test I



June 29, 10 a.m. With reproduction test.

	Stimulus word	*Reaction*	*Reaction-time (in ⅕-secs.)*	*Reproduction*
1.	head	-ache	6	
2.	green	-pip	33	
3.	water	–	–	
4.	to sting	bee	9	
5.	*angel* (*Engel*)	-court (*-hof*)[3a]	105	–
6.	*long*	knife	65	–
7.	*ship*	steamship	35	–
8.	*to plough*	field	21	garden
9.	wool	to knit	75	
10.	friendly	-ness	11	
11.	table	-leg	30	
12.	to question	–	–	
13.	state	–	–	
14.	stubborn	stubborn person	40	
15.	stalk	flower-stalk	11	
16.	to dance	dance-floor	10	
17.	lake	Lake Zurich	29	
18.	sick	–	–	
19.	pride	conceit	19	
20.	to cook	cookery school	13	
21.	ink	ink-pot	9	
22.	bad	badness	39	
23.	pin	pincushion	10	
24.	to swim	swimming-school	45	
25.	*travel*	travelling-rug	60	
26.	blue	Blue Street	35	
27.	bread	breadless (unemployed)	20	
28.	*to threaten*	punishment	60	to punish
29.	lamp	lampshade	11	
30.	rich	riches	21	
31.	tree	fruit-tree	23	
32.	to sing	singsong	16	
33.	pity	regret	35	

34. yellow	yolk	26	
35. mountain	Mount Utli	23	
36. to play	chess	16	
37. salt	salt-cellar	12	
38. new	Neumünster	15	
39. morals	morality	46	
40. to ride	riding-school	18	
41. *wall*	wallpaper	12	–
42. *silly*	silliness	45	–
43. exercise-book *(Heft)*	school-book *(Schulheft)*	15	
44. to despise	–	–	
45. *tooth*	eye-tooth	15	–
46. *right*	to make right	25	–
47. people	People's Press	23	
48. *to stink*	jackdaw	50	–
49. book	school-book	15	
50. unjust	–	–	
51. frog	tree-frog	25	
52. to separate *(Scheiden)*	divorce *(Ehescheidung)*	32	
53. hunger	to eat	19	
54. white	snow	18	
55. cattle	herd of cattle	32	
56. to attend	attention	30	
57. pencil	pencil-holder	31	
58. dull	–	–	
59. plum	plum jam	66	
60. to hit	–	–	
61. law	–	–	
62. love	unloving	15	
63. glass	water-glass	8	
64. *to argue*	to quarrel	23	–
65. goat	goat's milk	12	
66. grand	grandeur	15	
67. potato	potato-flour	20	
68. to paint	oil-painting	21	
69. part	part-payment	26	



70. old (*alt*)	Altstetten	49	
71. flower	bunch of flowers	51	
72. *to strike*	hammer-stroke	30	–
73. cupboard	linen-cupboard	21	
74. wild	wild duck	21	
75. family	family dinner	26	
76. to wash	–	–	
77. cow	cow's milk	10	
78. guest	guest-book	30	
79. luck	good luck	53	
80. to tell	tale	15	
81. manners	training in manners	55	
82. narrow	–	–	
83. brother	–	–	
84. shame (*Schade*)	shame-joy (*Schadenfreude*)	10	
85. stork	stork's nest	26	
86. false	falsehood	37	
87. anxiety	feeling of anxiety	20	
88. to kiss	sister's kiss	65	
89. fire	great fire	28	
90. dirty	–	–	
91. door	lock	21	
92. to elect	election for the Co-op	55	
93. hay	hay-cart	19	
94. still	rest	39	
95. *ridicule*	ridiculous price	10	ridiculously cheap
96. to sleep	sleeplessness	17	
97. month	monthly meeting	15	
98. coloured	–	–	
99. dog	faithful dog	15	
100. to talk (*reden*)	consultation (*Sprechstunde*)	67	

[796] This test was given during the consultation. Let us first look at the associations from the statistical angle. I am limiting myself to the classification into internal and external associations, sound reactions, failures, and indirect associations.[4] This rough classification suffices for our purposes. The patient produced:

Internal associations	16%
External associations	60
Sound reactions	9
Failures	14
Indirect associations	1
Incorrect reproductions	14

[797] External associations form an exceptionally large majority. The patient, though not unintelligent, lacks higher education (she has only had an elementary education and was often absent from school). A

glance at the reactions shows that the external associations consist mainly of combinations of motor verbal patterns, of word compounds. Besides these we also find quite a number of word complements (sound reactions). The large number of failures is striking. If we compare the figures with the average figures for educated women:[5]

Average for Educated Women

Internal associations	35.0
External associations	58.0
Sound reactions	3.3
Failures	1.4

we see that the patient's figures show a much more superficial mode of association; they approximate to the figures of the distraction experiment. Average of the distraction experiment with 100 metronome beats per minute:

Educated Women excluding the Predicate Type

Internal associations	20.8
External associations	62.8
Sound reactions	13.2
Failures	0.4

[798] Thus one might think that the attention was distracted during the experiment. This leads to the question of the cause of the distraction, i.e., what was it that had a disturbing influence? No external causes could be found. Therefore the possibility of a psychological interference must be considered. We need not go far in our search, because the patient is already full of a subject that makes every interest in her environment fade, namely, the complex of ideas regarding her illness. All her attention is riveted to her symptoms and only a small remnant is available for the association experiment; hence the superficial reaction-type. She is so much absorbed by her illness that she hardly allows the meaning of the stimulus-word to reach her; in most cases she is quite satisfied simply to grasp the outer form of the word and her intellectual effort is confined to finding a commonplace association to the stimulus-word. She listens with only "half an ear" and lets the stimulus-words, as it were, slip away from

her. She cannot bring herself to devote her attention to the experiment; this is apparently not interesting enough compared with the complex. The small amount of self-control sometimes dwindles to nothing (failures), and this actually often happens wherever a commonplace combination of words is not ready on the tip of her tongue; this also often occurs when the stimulus-word has aroused emotionally charged associations, as we shall see later. As soon as she realizes that the reaction is not at her fingertips, she completely refrains from forcing one. Here the experiment reveals the meaning of the clinically conspicuous aboulia, which, as usual, consists in the fact that the whole interest is absorbed by the complex, i.e., by the hysterogenic complex underlying the manifest illness, so that nothing remains for the environment.[6]

[799] The probable mean of the reaction-times of the experiment is 5.2 seconds; it is thus very high. We believe that such prolonged intervals are due to certain emotional inhibitions.

[800] As in the case reported in "Psychoanalysis and Association Experiments," an analysis of the patient was impossible because she appeared quite indifferent and did not want to deal with any questions that did not concern her symptoms. The repression, i.e., the inhibition arising from the pathogenic complex, was at that time still too strong.

[801] After the consultation during which this test was taken, the patient went home again. As already mentioned, the illness grew rapidly worse. Three months later she was admitted to this hospital.

Test II

October 5, 5 p.m.

1. head	headache	1.6
2. green	−	−
3. water	water-works	2.8
4. to sting	stinging-nettle	2.4
5. angel	−	−
6. long	long-winded	2.2
7. ship	−	−
8. to plough	−	−
9. wool	cotton-wool	2.2

10. friendly	friendliness	3.0
11. table	table-mate	2.2
12. to question	question-mark	6.6
13. state	−	−
14. stubborn *(trotzig)*	stubborn person *(Trotzkopf)*	3.2
15. stalk	flower-stalk	6.0
16. to dance	dance-floor	4.0
17. water	water-lily	9.0
18. sick	sickly	3.4
19. pride	−	−
20. to cook	−	−
21. ink	ink-blotter	4.6
22. bad	badly	−
23. pin	pincushion	2.4
24. to swim	swimming-pool	4.0
25. travel	−	−
26. blue	−	−
27. bread	−	−
28. to threaten	−	−

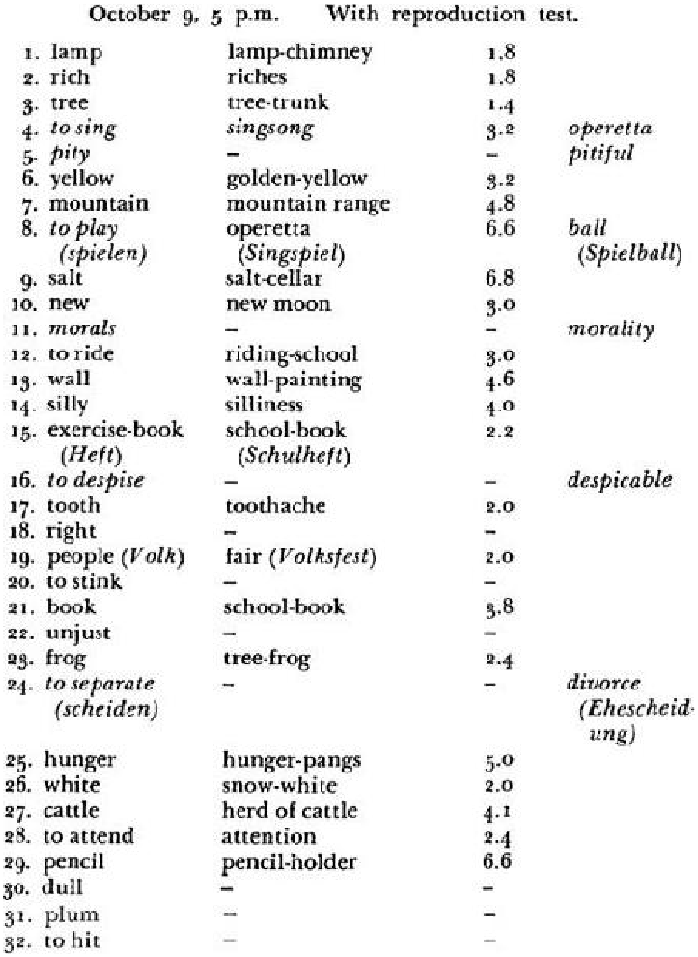
[802] The patient gave up completely at No. 28, declaring she could not stand any more. She could not be induced to stay in the consulting room any longer. Therefore it was not possible to make a reproduction test. An analysis was equally impossible. Nevertheless a number of points emerge from the result. Above all, one is again struck by the peculiar character of the associations: there is nothing but word combinations and there are numerous failures. Expressed in percentages there are:

Tests	*I*	*II*
Internal associations	16%	0%
External associations	60	46.4
Sound reactions	9	14.2
Failures	14	39.2
Indirect associations	1	0

[803] This is quite an unusual picture. The patient’s behaviour during the test was characteristic. She held her head in both hands, and from time to time she sighed because of the unbearable heat in her head, caused by the heated room (55°F.! The patient is unaware that she experiences 55° as pleasantly cool in summer, while she finds the same temperature unbearable in winter. The operative factor in the air temperature is the mere concept!) During the test she obviously was completely absorbed by the complex. It is not surprising therefore that she could not spare any attention for the tedious experiment. Thus we have a distraction phenomenon again, but in a considerably higher degree than in Test 1. The deterioration of her condition decidedly increased the distraction of her attention; i.e., her attention is, even more than previously, directed towards the complex, so that she participates less in the experiment. To direct the attention towards the experiment is obviously very strenuous for her, so that she is already tired after 28 reactions and has to abandon the test. Her available energy has been reduced to a minimum. This is already shown in the enormous number of failures, which have almost tripled compared with the first test. She again fails at stimulus-words that do not immediately arouse a commonplace combination of words. But not all failures can simply be due to the lack of commonplace word combination (e.g., for *to cook* there are the common combinations *cooking-stove, cookery,* etc.; for *state* there are *statecraft, state-house,* etc.; for *travel, travelling bag,* etc.). Nor can all the long reaction-times be accounted for by verbal difficulties (e.g., *water,* with 9.0 secs., with which there are many common combinations). We must also consider the possibility of these disturbances being caused by affects that may be due to unconscious inhibitions arising from the pathogenic complex underlying the illness.

[804] The probable time-mean of the test is 5.2 seconds (the failures taken as 20.0 secs., though usually we waited up to 30 secs.). The probable mean is therefore very high.

Test III



October 9, 5 p.m. With reproduction test.

1. lamp	lamp-chimney	1.8	
2. rich	riches	1.8	
3. tree	tree-trunk	1.4	
4. *to sing*	*singsong*	3.2	*operetta*
5. *pity*	–	–	*pitiful*
6. yellow	golden-yellow	3.2	
7. mountain	mountain range	4.8	
8. *to play (spielen)*	operetta (*Singspiel*)	6.6	*ball (Spielball)*
9. salt	salt-cellar	6.8	
10. new	new moon	3.0	
11. *morals*	–	–	*morality*
12. to ride	riding-school	3.0	
13. wall	wall-painting	4.6	
14. silly	silliness	4.0	
15. exercise-book (*Heft*)	school-book (*Schulheft*)	2.2	
16. *to despise*	–	–	*despicable*
17. tooth	toothache	2.0	
18. right	–	–	
19. people (*Volk*)	fair (*Volksfest*)	2.0	
20. to stink	–	–	
21. book	school-book	3.8	
22. unjust	–	–	
23. frog	tree-frog	2.4	
24. *to separate (scheiden)*	–	–	*divorce (Ehescheidung)*
25. hunger	hunger-pangs	5.0	
26. white	snow-white	2.0	
27. cattle	herd of cattle	4.1	
28. to attend	attention	2.4	
29. pencil	pencil-holder	6.6	
30. dull	–	–	
31. plum	–	–	
32. to hit	–	–	

[805] This test shows some changes compared with the previous ones. The result expressed in percentages is as follows:

Tests	*II*	*III*
Internal associations	0.0%	3.1%
External associations	46.4	59.3
Sound-reactions	14.2	6.2
Failures	39.2	31.2
Incorrect reproductions	–	18.7

[806] Here we have one more distraction-experiment. The probable time-mean is

Test I	*Test II*	*Test III*
5.2 secs.	5.2 secs.	4.6 secs.

[807] Compared with the second test there is some shortening of the reaction-time, which is probably to be explained mainly by the relative reduction in the failures. This result may perhaps permit the conclusion that the patient had pulled herself together a little. This seems also to express itself in the fact that in spite of the early failure in the association test she was willing to do the reproduction test. This test also went four reactions further than the previous one (28, 32). The number of sound reactions has not inconsiderably decreased, to the benefit of the external and internal associations. This also allows us to infer some improvement in her concentration.

Test IV

October 17, 5 p.m. With reproduction test.

1. law	against the law	5.0
2. love	unloving	3.0
3. glass	glass-cupboard	2.0
4. to argue	–	–
5. goat	goat’s milk	2.8
6. grand	grand city	4.8
7. potato	potato-field	5.6
8. to paint	painter’s studio	5.4
9. part	partner	3.0
10. old	old town	9.6
11. flower	flowerlet	2.4
12. to strike	–	–
13. cupboard	linen-cupboard	5.6
14. wild	–	–
15. family	family dinner	4.0
16. to wash	–	–
17. cow	cow’s milk	3.2
18. guest	guest-book	3.4
19. luck	good luck	2.8
20. to tell	–	–
21. manners	training in manners	2.8
22. narrow	–	–
23. brother	–	–

24. shame *(Schade)*	shame-joy *(Schadenfreude)*	3.6
25. stork (stimulus-word first misunderstood−then failure)		
26. false	falsehood	8.2
27. anxiety	feeling of anxiety	3.0
28. to kiss	sister’s kiss	4.0
29. fire	fire-blackened	6.8
30. dirty	dirty marks	7.0
31. door	trap-door	4.8
32. to choose	−	−
33. hay	−	−
34. still	−	−

[808] This test was carried out at a time when the patient was not so well (one of those fluctuations that are not unusual in the course of hysteria). The test certainly again looks like a distraction experiment. Apart from one exception *(to kiss / sister’s kiss)* the patient so to speak never bothers with the meaning of the stimulus-word but contents herself with the perception of the outer word-form. There were no mistakes in reproduction. The test yielded two reactions more than the previous one (32, 34). In percentages:

Tests	*II*	*III*	*IV*
Internal associations	0.0%	3.1%	2.9%
External associations	46.4	59.3	58.8
Sound reactions	14.2	6.2	5.8
Failures	39.2	31.2	32.3
Incorrect reproductions	−	18.7	0

The probable time-mean is:

Tests	*II*	*III*	*IV*
	5.2 secs.	4.6 secs.	5.4 secs.

[809] Thus we again have an increase in the reaction-time, which we may ascribe to the unfavourable attitude of the patient at that moment. The lack of incorrect reproductions may, in view of the small number of reactions, be accidental, but it is also possible that this time the patient remembered the reactions in order not to make any mistakes with the reproduction later on.

Test V

November 9, 5 p.m. With reproduction test.

1. ridiculous	−	−	
2. *to sleep*	*rest*	1.8	*tired*
3. *month*	−	−	*time*
4. coloured	Negro	6.3	
5. dog	domestic animal	3.4	
6. to talk	to tell a story	4.8	
7. coal	to iron	4.0	
8. moderate	−	−	
9. song	tune	3.6	
10. to assume	facts	10.0	
11. *pain*	*ill*	5.2	*illness*
12. lazy	to work	5.4	
13. moon	−	−	
14. to laugh	merry	−	
15. coffee	breakfast	2.2	
16. wide	measure	3.6	
17. air	warm	5.0	
18. to frighten	anxiety	7.6	
19. plate	to eat	7.0	
20. *tired*	*to sleep*	4.4	*bed*
21. *intention*	*to damage*	7.4	?
22. to fly	−	−	
23. eye	−	−	
24. strong	vigorous	2.6	
25. fruit	−	−	
26. *to be busy*	*industrious*	3.0	*to work*

27. sail	ship	7.0	
28. modest	content	6.4	
29. ground (does not understand stimulus-word at first)	land	10.0	
30. to whistle	sound	6.4	
31. purpose	cause	3.4	
32. *hot*	yes, yes, in here	4.0	*light*
33. hand	limb	3.0	
34. *to wake*	*awake*	3.0	*to get up*
35. apple	don't know *Affeltrangen (place)*	13.6	
36. naughty	−	−	
37. mouth	teeth	7.2	
38. to drink	liquid	4.4	
39. *bed*	*tired*	7.2	*to sleep*
40. *pretty*	*beautiful*	40	?
41. *danger*	−	−	*terrible*
42. to visit	−	−	
43. *worker*	*occupation*	6.4	*to be occupied*
44. high	mountain	4.6	
45. axe	wood	9.4	
46. to remember	to watch	2.0	
47. path	a walk	5.0	
48. round	sphere	2.4	
49. *blood*	−	−	*red*
50. devoted	−	−	
51. precaution	to watch	−	
52. *funny*	*story*	4.8	*to laugh*

[810] This test shows quite a different association type compared with the previous tests. It is as if the patient had suddenly found a different attitude.[7] The percentages are as follows:

Tests	*II*	*III*	*IV*	*V*
Internal associations	0%	3.1%	2.9%	56.9%
External associations	46.4	59.3	58.8	18.9
Sound reactions	14.2	6.2	5.8	1.2
Failures	39.2	31.2	32.3	21.5
Indirect associations	0	0	0	1.2
Incorrect	−	18.7	0	21.3

reproductions

[811] Looking at the association tests, the results of which we have given here in figures, we see that the patient's reactions have assumed a normal character. She now goes into the meaning of the stimulus-word and thus produces a preponderance of internal associations.[8]

[812] The abnormal component parts have rather diminished, so that, for instance, the number of sound reactions does not exceed the normal mean. Only the number of failures is still abnormally high; it has, however, considerably decreased compared with the earlier tests. The patient's perseverance has increased remarkably, in that this test lasts longer by 45 reactions than the previous one. The time-mean is 5.4 seconds, as in the previous test. The reaction-time is thus still very long.

[813] This test was carried out three weeks after the previous one. In the meantime the treatment had clearly improved the patient's condition. Therefore one may ascribe the improvement of the association type also to this fact. In the previous tests we mainly stressed the lack of entering into the meaning of the stimulus-word, the absolute preponderance of external associations, the enormous number of failures, and the rapid onset of fatigue as pathological signs and as an abnormal domination of the patient's interest by the complex. The improvement in the condition is thus particularly expressed, from the psychological point of view, in the fact that the patient again takes a more or less sufficient though quickly tiring interest in objective processes. The treatment is resolving her possession by the complex. Her personality is gradually being freed from the tyranny of the illness and is again able to assimilate objective material, in other words to adapt itself again to the environment. As stigmata of hysteria the following are, however, still present: the enormous number of failures; the long reaction-times and other complex-characteristics, i.e., signs of a pathological emotionality, which is, as we know, the psychological foundation of hysteria.

Test VI

December 1, 5 p.m. With reproduction test.

[814] The test comprised one hundred reactions. It was concluded not because of the patient's fatigue, but because I considered one hundred reactions enough to analyze. I shall describe and discuss the test in individual sections.

[815] I should like to remark at the outset that the probable time-mean of this test is 5.2 seconds. It is thus not lower than the preceding ones. In spite of this apparent similarity, however, the temporal aspects are in their averages entirely different from those in the previous tests. For the purpose of discussing these relations I am splitting each test up into sequences of six to ten reactions, and for each sequence I have calculated the arithmetic time-means.[9] I have arranged the means thus obtained in curves below.

Test I. The curve fluctuates very much. Near the beginning there is a line of relatively short times which, after various fluctuations, rises higher and higher. Towards the end there are very strong increases in reaction-times which, however, are again somewhat shortened, but do not reach the initial level. The curve gives the impression that the patient has noticed the excessive times and therefore pulled herself together for a few reactions. Test I was carried out during the consultation. As reported in the case-history, the condition afterwards rapidly deteriorated. This deterioration shows in the curve of …

Test II. Here the curve starts rather high, and after pulling itself together for a short time it rapidly collapses.

In *Test III* the curve begins low. The patient had (as she told me at the time) made a resolution to take great pains this time to answer quickly. The carefully gathered energy, however, does not last; the reaction-times increase progressively until they become very high. The observation of this weakness probably induced the patient to a little spurt at the end which, however, exhausts the remains of her energy.

Test IV. The curve starts a little higher than last time (the patient was, as we mentioned before, indisposed psychologically at the time of this test). Here too there is a steady increase in the reaction-times.

Tests I–IV mainly yielded external associations and failures. We can already see from the curves that this mode of association is linked with rapidly increasing reaction-times.

Test V. Here the curve begins very high (perhaps to be explained by the fact that the patient was still discouraged by the previous tests and therefore had some resistance against the experiment). It decreases quickly, however, and then, after a stronger fluctuation stays near the centre, though rising slightly. Then there is a more noticeable and longer-lasting final spurt, which, however, ends in a quick and steady increase of the reaction-times. The final spurt has completely exhausted the patient's energy.

Test VI. In this last test (after two months' treatment) the curve begins at a medium height and then falls quickly to a very low level, which is fairly well maintained during the whole test without any appreciable fluctuations and only towards the end shows a tendency to rise. Test V shows, at least in its middle parts, a tendency towards steadiness, which is finally reached in Test VI. Tests V and VI are, however, those that show a normal mode of association. Thus the normal type appears to go with the tendency to steadiness in the reaction-times. At the same time a very low level is reached and maintained in Test VI.

I should like to mention that the one hundred stimulus-words given in Test I were used a second time in Tests II–IV and a third time in Test VI. As the curves show, repetition of the tests had no noticeable effect in reducing the reaction-times. Tests II–IV made one rather suspect the contrary. According to Kraepelin's findings, a relatively rapid shortening of the reaction-time is actually to be expected because of a fixation of the reactions. In Test VI, however, there are not only no fixations but entirely different reactions (in accordance with the new attitude that had first appeared in Test V).

[816] As has repeatedly been indicated in the discussion of the curves, the increased reaction-times are linked with a strong tendency towards fatigue, i.e., with a complete inability to detach the attention from the syndrome. The patient has great difficulty in directing her attention to anything but her illness for any length of time; because of the exertion

she tires very quickly. The curves representing the time-extensions are therefore also curves representing weakness of energy. This immediately becomes obvious when we turn them over and read them from right to left. Then they look like the *work-graphs* of an easily tiring neurotic (will-fatigue!). In particular we notice the facilitation and the increased reaction-times in curves I, V, and VI, the final spurt in curves I, III, and V. In curves I and VI the progressive fatigue is clearly marked. This shows that in certain cases the association experiment also gives information on energy and fatigue.

Analysis of the Associations Obtained in Test VI

I am setting the associations of Test VI side by side with those of Tests I–V for the purpose of analytical comparison (time in seconds):

Tests	*I*			*II–IV (V)*		*VI*	
1. head	-ache	1.2		headache	1.6	pa–head-pains	1.8
2. green	-pip	6.6		–		forest	3.2
3. water	–			water-works	2.8	deep	1.4
4. to sting	bee	1.8		stinging-nettle	2.4	bee	2.8
5. *angel*	-court	21.0	[?][10]	–		–	
6. *long*	knife	9.0	[?]	long-winded	2.2	road	5.0
7. *ship*	steamship	7.0	[?]	–		ocean	4.0
8. *to plough*	field	4.2	[garden]	–		to demand / to give	7.4
9. wool	to knit	15.0		cotton wool	2.2	(stimulus-word not understood) to knit	10.2
10. *friendly*	-ness	2.2		friendliness	3.0	–	[people]
11. table	(does not at first understand stimulus word, then:) -leg	6.0		table-mate	2.2	room	9.0

1: *head*, of course, arouses the complex in that the patient has localized the main symptoms in the head. Although the times are not long, we find a disturbance by a slip of the tongue in Test VI instead. The two previous reactions have the superficial character that we not infrequently find in complex-reactions and that are meant to make light of the complex.

3: *water* appears still to belong to the field of the perseverating feeling-tone.

5: *angel* shows complex-characteristics. The patient is not religious but still childlike. She has often during recent months had thoughts of dying; she even had one evening hallucination of the "black bone-man" stretching out his hand towards her. This is reason enough for the complex-interference. We have, however, to go even deeper. The patient has an intimate and confidential relation to her mother. The two women are moreover tied together through severe illness. The mother suffers from osteomalacia and is totally crippled. The mother is for the daughter not only an example in a moral respect but perhaps also a foreboding of her own fate. The fear of having to expect a fate similar to that of the mother may not be very far from the patient. Lastly, one has to remember the fact that young girls and hysterics talk of *dying* when they want *to love*.

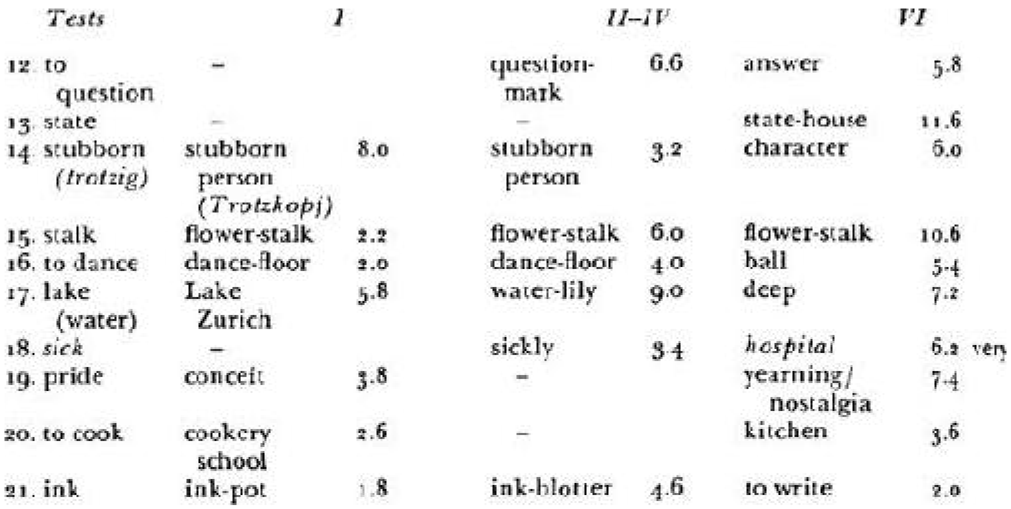
The disturbances last from *angel* to 8. In Test I there was even an amnesic island.[11]

In 8, another stimulus-word was substituted in Test VI to make the complex more precise: *to demand* is followed by 7.4 seconds, the next stimulus-word *wool* is misunderstood, with 10.2 secs. With *to demand* I get the patient to produce further ideas:

The patient literally says: "I thought you (the author) demanded too much of me, it is *too much* if you are always wanting me to get well." It seemed to me that the patient was somehow "skipping over it," although in hysterics the thought of the doctor who carries out the treatment tends to be associated with strong emotional charges.[12] Therefore I simply said: "*The* demand." The patient starts slightly, saying: "I don't know what you mean—I really cannot think what you can still want of me." Then she suddenly bursts out into loud laughter, blushes, and says no more. The progress of this analytical detail is as follows: First the patient accuses me of demanding too much of her, then there are the familiar negativistic excuses and lastly, behind laughter, a strong emotionally charged thought which may not be difficult to guess. The laughter is diagnostically important: it often indicates in psychoanalysis that a complex has been touched. It is obvious that no one but the patient *demands anything* that is *too much*. Freud says: “Many of my neurotic patients who are under psychoanalytic treatment are in the habit of confirming the fact by a laugh when I have succeeded in giving a faithful picture of their hidden unconscious to their conscious perception; and they laugh even when the content of what is unveiled would by no means justify this. This is subject, of course, to their having arrived close enough to the unconscious material to grasp it after the doctor has detected it and presented it to them.”[13]

10, *friendly* seems to be critical in Test II, but not in Tests I and VI.

Analysis: First there are strong inhibitions (“I don’t know anything,” etc.). Then “I was thinking of you, sir. You were not nice to me last time.” This reminiscence refers to a definite incident, when the patient had transposed her bad temper on to me and alleged afterwards that I had been in a nasty mood (“transitivism” in affect). This idea seems enough to explain the disturbance. I indicated before that the patient transposed the “demanding too much” on to me, she also fits me out with *her* bad temper and accuses me of being unfriendly to her. She thus *demands* that I should be friendly to her, and if I am as usual I am not friendly enough, for she still complains of my unfriendliness. So she wants even more friendliness from me; that allows me to conclude that the patient is erotically not indifferent to me. Of course, I cannot give in to this demand. Thus the patient demands too much. She only acquired this aspect of the complex while she was here. The complex disturbances may therefore increase at *friendly*.



Tests	*I*		*II–IV*		*VI*	
12. to question	–		question-mark	6.6	answer	5.8
13. state	–		–		state-house	11.6
14. stubborn (*trotzig*)	stubborn person (*Trotzkopf*)	8.0	stubborn person	3.2	character	6.0
15. stalk	flower-stalk	2.2	flower-stalk	6.0	flower-stalk	10.6
16. to dance	dance-floor	2.0	dance-floor	4.0	ball	5.4
17. lake (water)	Lake Zurich	5.8	water-lily	9.0	deep	7.2
18. *sick*	–		sickly	3.4	*hospital*	6.2 ver
19. pride	conceit	3.8	–		yearning/ nostalgia	7.4
20. to cook	cookery school	2.6	–		kitchen	3.6
21. ink	ink-pot	1.8	ink-blotter	4.6	to write	2.0

In 12, *to question*, obvious complex-disturbances are aroused that involve the subsequent reaction as well.

Analysis: “I thought the Doctor was asking me a lot, I know absolutely nothing more—I certainly don’t know anything else.” The patient said this with emphasis and an angry ill-humoured face, which was in striking contrast to her usual politeness and submissiveness; then she suddenly burst out into loud laughter, which she tried to suppress by expressing anger: “Oh, what a strain!”—“This is impossible!”—“I have never thought of that!,” because she did not think of the special and, for a young girl, so immensely important meaning of the word *question* at the moment of the reaction. She thinks this meaning has only now occurred to her; “of course, she never thinks of such a thing otherwise.” Thus we have here a further indication of the presence of an erotic complex.

16: *stubborn* is very suitable to bring out a reference to the ego. Particularly if the reaction to it is *character* or *quality* or *misbehaviour*, we may suspect the subject of the experiment behind it. With *character* the reference to the ego becomes obvious, hence probably also the stronger disturbances, compared with the previous reactions.

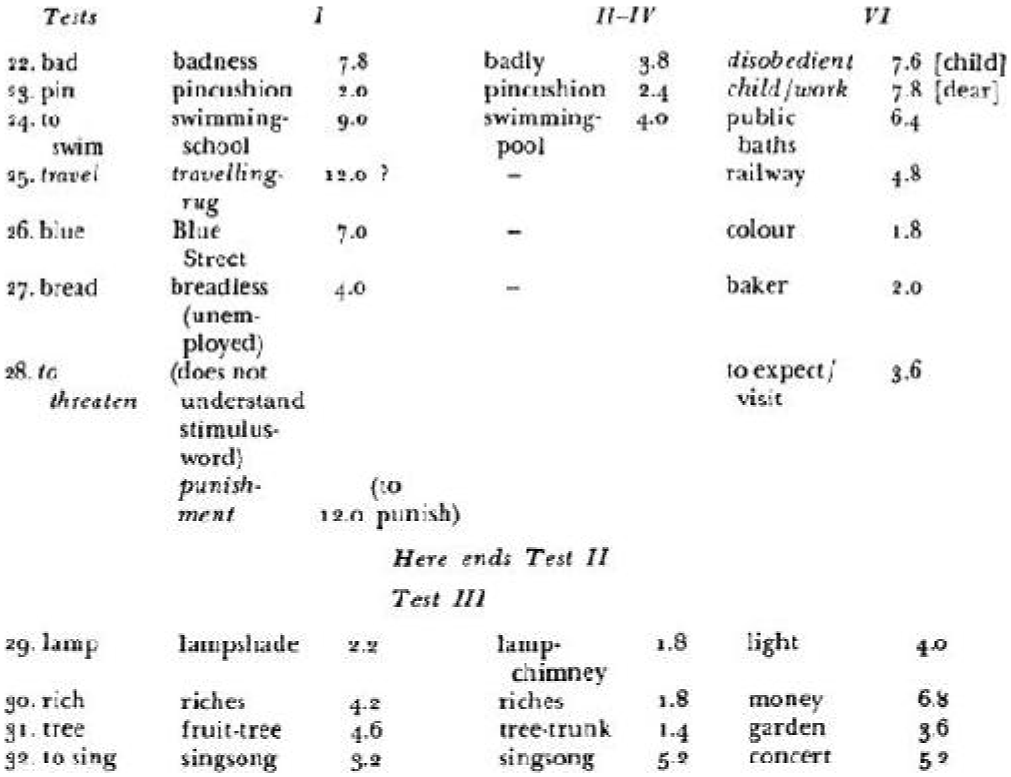
Analysis: “People are often stubborn—for instance, I was, too, when I was a child. Once I was rather stubborn and did not want to go to school any more—I was twelve years old then, I think. From then on I did not go to school.”

It is known that the patient could no longer go to school because of her St. Vitus's dance; now she interprets this illness as misbehaviour, and here she even says she did not go to school any more out of *stubbornness*. But if we ask her in another context why she no longer went to school, then she says she was very ill at that time. For the moment we must be satisfied with this information. The twelfth year of life has, however, another significance which is infinitely more important, as we shall see later on.

Like *stubborn/stubborn person*, 16, *to dance/dance-floor* skips over the deeper meaning. Only the reaction *ball*, which goes more thoroughly into the meaning of the stimulus-word, brings about a distinct complex-disturbance. *Dance-floor*[14] is something that is abhorrent to the circles to which the patient belongs, while *ball* is actually the legitimate opportunity to start erotic relationships. The patient is compelled to laugh when she is asked for associations to *ball;* she therefore may well have erotic ideas.

In 19, *yearning* was given as a stimulus-word in Test VI.

Analysis: The patient declares stubbornly and with obvious resistance that absolutely nothing but *nostalgia* comes to her mind in response to *yearning*. I insisted something would occur to her. To this, suddenly loud laughter, which is at once angrily suppressed: "Oh no, now that spoils it for me—this is boring!" We had the same reaction to *demand*. There is probably a strongly repressed erotic desire.



Tests	*I*		*II–IV*		*VI*		
22. bad	badness	7.8	badly	3.8	*disobedient*	7.6	[child]
23. pin	pincushion	2.0	pincushion	2.4	*child/work*	7.8	[dear]
24. to swim	swimming-school	9.0	swimming-pool	4.0	public baths	6.4	
25. *travel*	*travelling-rug*	12.0 ?	–		railway	4.8	
26. blue	Blue Street	7.0	–		colour	1.8	
27. bread	breadless (unemployed)	4.0	–		baker	2.0	
28. *to threaten*	(does not understand stimulus-word) *punishment*	12.0	(to punish)		to expect/visit	3.6	

Here ends Test II

Test III

29. lamp	lampshade	2.2	lamp-chimney	1.8	light	4.0
30. rich	riches	4.2	riches	1.8	money	6.8
31. tree	fruit-tree	4.6	tree-trunk	1.4	garden	3.6
32. to sing	singsong	3.2	singsong	5.2	concert	5.2

22: *bad* is taken personally; *disobedient* seems to express the complex best.

Analysis: "I was bad to you the other day—years ago too I was often bad—and disobedient at school, etc."

23: The association *child/work* is peculiar and cannot be explained by the patient. The reproduction yields the more suitable association *dear*. Preceding is the school-complex, which is most closely connected with the concept of *work*. I should like to remind the reader that the stimulus-words *to work* and *worker* in Test V produced complex-disturbances. Moreover, the patient always stresses that she is not "lazy," she would like to do the right kind of work; she also complained of certain relatives who said of her that all she was suffering from was "laziness." The stimulus-word *child* is a word which, as a rule, has a critical effect in the erotic complexes of women.

There are complex-characteristics in 25: *travel*.

Analysis: "Oh, I am thinking of a nice journey to Italy that I should like to do one day"—long interval. With great embarrassment:

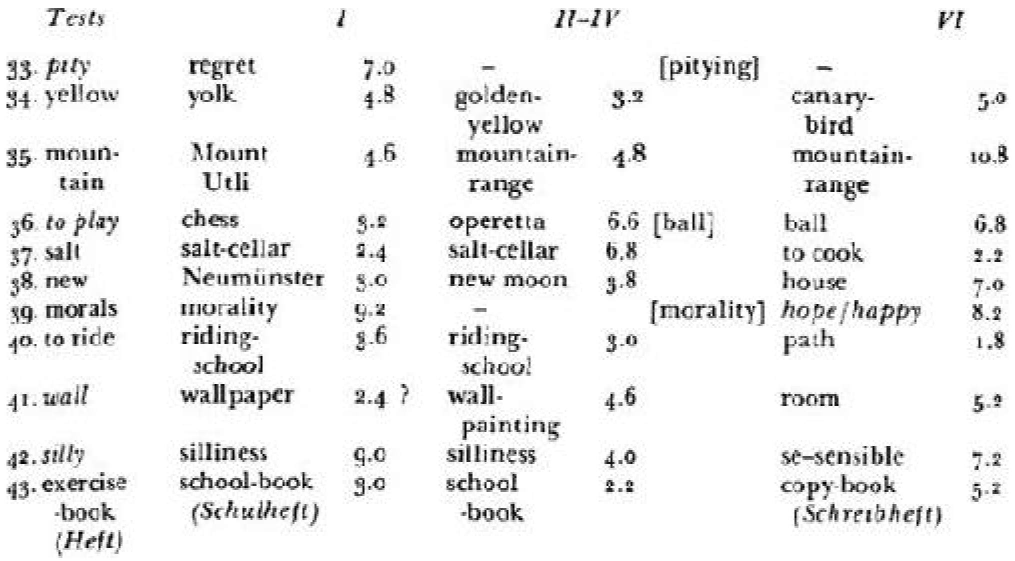
"Honeymoons are spent in Italy, too."

28, Test VI: *to expect*.

Analysis: "I don't expect anything—absolutely nothing—yes, health —and—," loud laughter again which the patient tries angrily to suppress. Thus the same reaction again as to *demand* and *yearning*.

30: *rich*.

Analysis: "I should like to be rich, then I could stay here a long time for treatment"; then there are strong inhibitions that bar any further ideas. For the patient "to stay a long time for treatment" equals "to remain for a long time in a personal relationship to the doctor."



Tests	*I*		*II–IV*			*VI*	
33. *pity*	regret	7.0	–		[pitying]	–	
34. yellow	yolk	4.8	golden-yellow	3.2		canary-bird	5.0
35. mountain	Mount Utli	4.6	mountain-range	4.8		mountain-range	10.8
36. *to play*	chess	3.2	operetta	6.6	[ball]	ball	6.8
37. salt	salt-cellar	2.4	salt-cellar	6.8		to cook	2.2
38. new	Neumünster	3.0	new moon	3.8		house	7.0
39. morals	morality	9.2	–		[morality]	*hope/happy*	8.2
40. to ride	riding-school	3.6	riding-school	3.0		path	1.8
41. *wall*	wallpaper	2.4 ?	wall-painting	4.6		room	5.2
42. *silly*	silliness	9.0	silliness	4.0		se–sensible	7.2
43. exercise-book (*Heft*)	school-book (*Schulheft*)	3.0	school-book	2.2		copy-book (*Schreibheft*)	5.2

R.33: *pity*.

Analysis: "I cannot imagine at all what *pity* might have to do with me —oh, perhaps with my illness—people ought to pity me."

I give here only one example of the inhibitions the patient had about this word: in fact, the resistance lasted much longer and also showed itself in a suffering facial expression. The tendency to arouse pity is of great significance in the history of the patient's illness. Through her illness she achieved not having to go to school any more. Later on she was the "pitied" centre of the whole family. The patient must have some, though dim, awareness of this role; it may perhaps be the origin of the strong resistance.

35: *mountain*.

Analysis: Does not want to know anything about it, she has nothing to do with mountains, this is no concern of hers. She has also never been on a mountain, although she would like to go once to the Alps, but this is, of course, impossible because of her illness, and then she cannot even travel by rail, she cannot stand it.

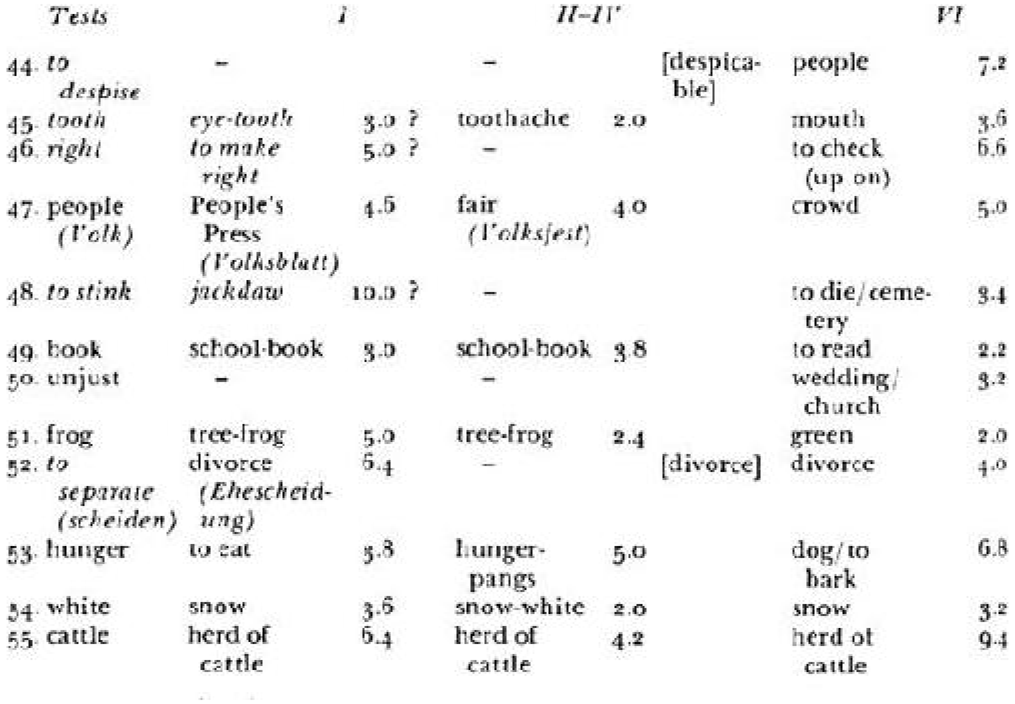
The patient speaks quite negatively, as if a mountain-trip was of no importance to her. A few days before the test I made a trip into the mountains, after which the patient was unhappy because I had not taken her with me; she had never seen the mountains close to. She completely repressed this incident, without actually any obvious reason, unless “travelling” was of a certain complex-significance. She has all sorts of erotic fantasy relations to the doctor. A journey with the “erotic symptom figure” is a metaphor for a “honeymoon.” This is probably the reason why this event was sexually repressed.

38: *new*.

Analysis: The patient has become an intimate friend of a lady who moved into a *new house*, to which the patient takes a peculiar liking. She envies the lady particularly for the way she runs her house. “I shouldn’t mind something like that.” This interest seems to be symptomatic. The analysis meets with great resistances (“one often moves into a new house—we at home also have a new apartment,” etc.). I now ask pointedly: “When does one move into a new house?” This rather general question causes the patient great embarrassment, she blushes and confesses: “When one gets married.” Thus she has assimilated the “new house” to her erotic complex.

39. (Test VI): *hope*. The analysis at once produces lasting giggles and that says enough. The laughter here is, however, very inadequate. R.23, *child* also produced a disturbance. We shall come back to this complex at 69.

42: *silly*. The analysis yields self-reproaches about the time when the patient left school for good (12th year of her age). She reproaches herself for not having learned enough because of lack of energy, and for being therefore "silly."



Tests	*I*		*II–IV*			*VI*	
44. *to despise*	–		–		[despicable]	people	7.2
45. *tooth*	*eye-tooth*	3.0 ?	toothache	2.0		mouth	3.6
46. *right*	*to make right*	5.0 ?	–			to check (up on)	6.6
47. people *(Volk)*	People's Press *(Volksblatt)*	4.5	fair *(Volksfest)*	4.0		crowd	5.0
48. *to stink*	*jackdaw*	10.0 ?	–			to die/cemetery	3.4
49. book	school-book	3.0	school-book	3.8		to read	2.2
50. unjust	–		–			wedding/church	3.2
51. frog	tree-frog	5.0	tree-frog	2.4		green	2.0
52. *to separate (scheiden)*	divorce *(Ehescheidung)*	6.4	–		[divorce]	divorce	4.0
53. hunger	to eat	3.8	hunger-pangs	5.0		dog/to bark	6.8
54. white	snow	3.6	snow-white	2.0		snow	3.2
55. cattle	herd of cattle	6.4	herd of cattle	4.2		herd of cattle	9.4

44: *to despise*.

Analysis: The patient always feels slighted; she felt her incomplete education as something for which she must be despised; people also despised her for her illness, which they interpreted as laziness. Is there perhaps anything else in her illness that makes her particularly despicable? We know that sexual self-reproaches tend to be connected with this.

46: *right* also shows disturbances. The analysis yields only generalities that are difficult to interpret. Is there perhaps anything in her activities that is not or was not "right"?

53 (Test VI): *dog* has a very long reaction-time (6.8 secs.).

Analysis: The patient has dreamed of dogs, which probably have an erotic significance (see below!).

Tests	*I*		*II–IV*		*VI*	
56. to attend	attention	6.0	attention	2.4	attention	2.8
57. pencil	pencil-holder	6.2	pencil-holder	6.5	black	5.0
58. dull	–		–		weather	2.0
59. plum	plum jam	8.3	–		cat/domestic animal	8.0
60. to hit	–		–		marksman	3.6

End of Test III

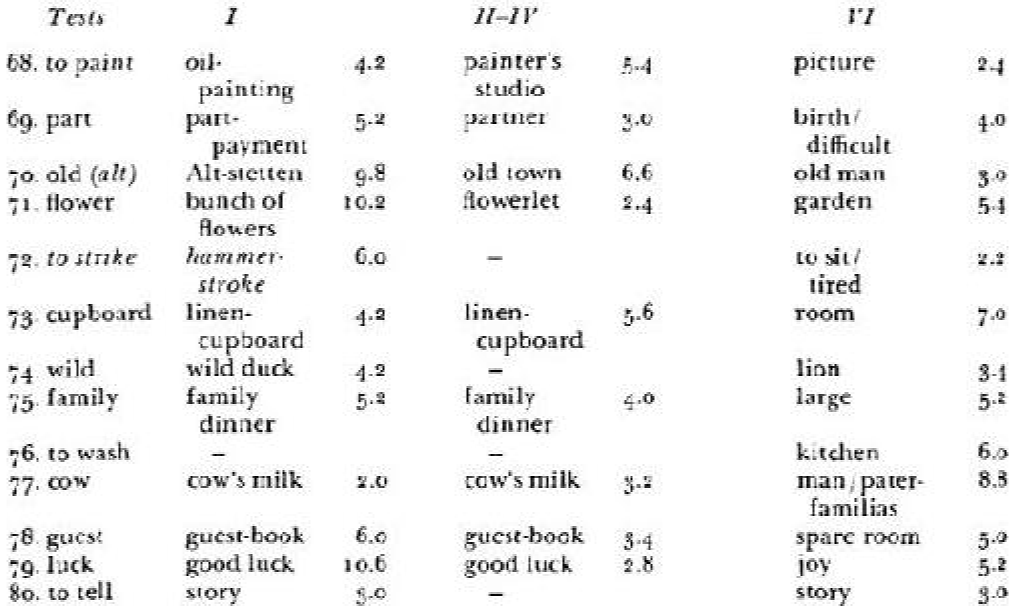
Test IV

61. law	–		against the law	5.0	against the law	5.4
62. love	unloving	3.0	unloving	3.0	child	2.0
63. glass	water-glass	1.6	glass-cupboard	2.0	bottle	8.0
64. *to argue*	*to quarrel*	4.6 ?	–		discord	7.8
65. goat	goat's milk	2.4	goat's milk	2.8	fire/house	3.8
66. grand	grandeur	3.0	grand city	4.8	ocean	11.0
67. potato	potato-flour	4.0	potato-field	5.6	dish (food)	6.8

57: *pencil*.

Analysis: The patient thinks of those tests when I sat opposite her and, while she did addition, occasionally made marks with a blue pencil in her exercise-book.[14a] Nothing else occurs to her after this idea. These tests took place shortly before Test VI. It may thus only be a reminiscence which, however, must somehow be constellated. One might perhaps suspect a masturbation-complex or another sexual fantasy. During the whole time of the treatment I avoided the topic of sex as much as possible, and only towards the end did I come to speak of it. If, therefore, a masturbation or other physical sexual complex was present, it was not aroused during the treatment (i.e., by Test VI), and thus could become more or less dormant, particularly when it was not being activated. Tests I-IV took place at the beginning of the treatment, when the complexes were still very active. Test VI was not carried out until the third month. This might explain the lack of complex-characteristics in this part of Test VI. In Test I the after-effect may last up to R.61.

In R.62, the more obvious hint, *child*, has a stronger perseverating effect than the former superficial *unloving*.



Tests	*I*		*II–IV*		*VI*	
68. to paint	oil-painting	4.2	painter's studio	5.4	picture	2.4
69. part	part-payment	5.2	partner	3.0	birth/difficult	4.0
70. old (*alt*)	Alt-stetten	9.8	old town	6.6	old man	3.0
71. flower	bunch of flowers	10.2	flowerlet	2.4	garden	5.4
72. *to strike*	*hammer-stroke*	6.0	–		to sit/tired	2.2
73. cupboard	linen-cupboard	4.2	linen-cupboard	5.6	room	7.0
74. wild	wild duck	4.2	–		lion	3.4
75. family	family dinner	5.2	family dinner	4.0	large	5.2
76. to wash	–		–		kitchen	6.0
77. cow	cow's milk	2.0	cow's milk	3.2	man/paterfamilias	8.8
78. guest	guest-book	6.0	guest-book	3.4	spare room	5.0
79. luck	good luck	10.6	good luck	2.8	joy	5.2
80. to tell	story	5.0	–		story	3.0

69 (Test VI): *birth/difficult*.

Analysis: “My mother had difficult labours; she has told me that her illness was caused by childbearing” (let us remember here 23, *child/dear*, and 39, *hope/happy)*. Although R.69 does not show any external complex-characteristic that is especially conspicuous, it contains a clear description of the complex. The mother’s fate is bound to be a warning to the daughter, because it is easy for her to be afraid that if she gets married she might also become a victim of osteomalacia. It would not be surprising then if the sexual fantasies carried rather gloomy emotional charges and therefore could be maintained only under a certain mental reservation, i.e., in the repression, because then there would not be any pleasurable expectation attached, but a strong feeling of unpleasure. This realization came perhaps rather early and had its share in the construction of the syndrome.

76: *to wash* with its conspicuous disturbances can have been constellated by *family* or by her obsessive cleanliness (see also the analyses of the dreams!).

77: That there is something attached to *family* becomes obvious in *man/paterfamilias*, 8.8 secs.

Tests	*I*		*II–IV*			*VI*

81: *manners* tends to stimulate sexual complexes.

In 85, with *stork*, there are marked disturbances that can be related to the stimulus-word (the erotic meaning of which is of course well known) as well as to the preceding *accident*.

88: *to kiss* is rather harmlessly disguised by *sister's kiss* and clearly shows the naïve compulsion to repress (similarly *stork/to fly)*. But perhaps *sister's kiss* has a very deep meaning that I could not have suspected at the time of the test (see the dream-analyses!).

89: *fire* shows long reaction-times throughout. *Fire* is one of the expressions by means of which the patient describes the head-symptoms. The response *house* is constellated by the dreams of fire in which she often sees houses ablaze.

92: *to elect* produces the utterly forced reply *election for the Co-op*.

Analysis: “One can elect (choose) a number of things, for instance a town councillor or anyone else”—(resistance, then giggling and embarrassment). We have already long known what a young girl associates with “choosing”; it is actually a “co-operative choice,” namely, someone who co-operates for life. This probably explains the disturbances that follow, because this is the “burning” question *par excellence*.

97: *month* often excites the image of the period in a woman, which in our case has a special significance. Hence the complex-disturbance.

Summary of the Analysis

[817] The association experiment and the analytical investigation into its results have given us insight into numerous trains of thought which, however, are still only vaguely differentiated. The analysis had to struggle with special difficulties because very few reactions in the three series appear normal. There is an abundance of complex-characteristics, which is further experimental evidence of how much the patient is overpowered by her complexes; we can almost say that not she but her complexes have the last word. The analysis not only met with great difficulties in getting at the critical reactions, because of the numerous complex-characteristics, but its task is made much more complicated by having to try to elicit further thoughts from the patient. Frequently the patient stops after only a few generalities and her laughter betrays that something is flashing through her mind. Interpretations that the patient can confirm are rare. She is so much under the influence of the complex that, if she were asked to evaluate its emotional significance, she would not be able to do so and would not know whether it is important or not. We depend therefore almost entirely on conjectures, which, however, permit certain conclusions.

[818] I have picked out only certain complex-constellations, although there are quite a number of others present. The associations produced in these are, however, only of secondary importance, so that I omitted their analysis for the sake of brevity.

[819] There are a good many associations that show complex-characteristics throughout all three series and which therefore have to be

understood as constant complex-constellations. In the majority of these cases a rather uniform interpretation is possible. Thus, for instance, it cannot be doubted that erotic ideas play an important part; they allow us here and there to recognize references to the doctor. In the second place comes the illness-complex. These two complexes, apparently independent of one another, have some aspects, however, in which they meet.

[820] In analogy to the illness of the patient is the illness of the mother which, in its turn, touches the sexual complex of the daughter *(birth / difficult*, etc.). There are also certain signs that it is perhaps a physical sexual complex. Lastly, there is also a school complex present.

[821] With these statements a number of threads has been provided that may lead us through the maze of the patient's thoughts. Because of her lack of self-control and her helplessness in the face of her complexes, however, the patient brings us into a precarious position in which we have to look for other means of finding confirmation of our assumptions.

[822] Nature has an apparatus that makes an extract of the complexes and brings them to consciousness in an unrecognizable and therefore harmless form: this is the *dream*. As I thought I had found only the general idea with the association experiment, I collected the patient's dreams. From the beginning nothing but stereotyped blood and fire dreams were related, and these only in a vague form. One had of course to be prepared to obtain material from the past, only after it had been carefully sifted. Everything that was too obvious had been obliterated by strong inhibitions. Also, during the observation the patient dreamed very little, i.e., she remembered only a few dreams. Unfortunately, therefore, the material is not as plentiful as one could wish.

II. THE DREAMS

[823] During the early months of the treatment I often inquired about her dreams. They were said to be infrequent; now and then the patient said she had again dreamed of *fire*, or of *blood:* "The whole room was full of fire or blood." Now and then she dreamed that blood was spurting from

all the openings in her head, or she dreamed the same of another patient whom, in the dream, she saw in her room. The patient did not mention anything of any other dreams. The blood and fire dreams seemed to me to be stereotyped expressions of the dream-life, as the heat-sensations were of the waking life, which first of all symbolically represented the patient’s phraseology (she had too much blood in her head, the blood was too hot; she had a temperature of 104°, she ought to be able to bleed properly once, everything in her head was like fire, everything was parched and charred, etc.). In the second place, the stereotyped dreams are, as always, symbolical expressions of the complex, which we have not yet clearly defined. For the therapeutic purpose of setting her against these dreams, which were often accompanied by anxiety, and for the theoretical purpose of learning whether she would abandon the dream-stereotypes and substitute something else for them, I said to the patient casually: “Blood is red, red means love, fire is red and hot, surely you know the song: No fire, no coal can burn as hot, etc. Fire, too, means love.”

[824] This interpretation made a strong impression on the patient. She burst out laughing with marked embarrassment. So she responded with feeling to my interpretation. My naïve interpretation of the dreams was based on the assumption that the dream symbolism would be simple and childish, in accordance with the patient’s mentality. The interpretation took place in the middle of November. In the second half of November the following dreams occurred:

[825] FIRST DREAM (Nov. 27). *“The room is full of cats, which are making a terrific noise.”* During the dream, strong anxiety with anger. Details were denied. The above rather general statement had to stand.

[826] The analysis was carried out in the same way as with the associations; I made her produce the first ideas that came to mind, avoiding all suggestive remarks and pressing only if the patient appeared to succumb to a stronger inhibition. (The decrease of energy at the approach of a complex, the failure to respond in critical places, etc. are the same.) I should like to point out that in all the coming analyses the result is mentioned beforehand each time, while the material follows in

small print. Anyone who is interested in the result only can skip the material.

[827] *Result of the analysis:* The patient lived for eleven years in a place where she was frequently disturbed by caterwauling. This noise is known to be caused by mating fights. Behind the manifest dream-content is concealed the idea of sexual intercourse.

Material. Ideas relating to cats: The patient: “During recent nights there were now and then cats in the garden outside my room. I can’t think of anything else—nothing at all (note the strong negations which are forerunners of an intensive inhibition. I insist)—I can think of absolutely nothing—yes, we had a lovely Angora cat once upon a time; unfortunately it was stolen.” It is definitely peculiar that such a simple reminiscence should be subjected to such strong inhibitions; one has therefore to assume that this reminiscence has yet another aspect of personal significance. I therefore make her continue to associate: “(sounding angry) There are many cats that jump through our garden, yellow, black, white ones—I don’t know what you want—(becomes very indignant, as if she were being forced to do something disgusting)—really, I can’t think of anything else.” This very decisive refusal has to be cut short; so I ask: “Were you disturbed by caterwauling at night?” “Never; it was actually quite impossible, because where I sleep at home one cannot hear the cats at all—as I said, I was never disturbed by cats—(in a casual tone, as if by the way) Oh, I remember that when I was ten or eleven, no, twelve years old (!), we lived in a place where there were always very many cats. They often made such a terrific noise at night that one thought the house would fall down. There were often about sixteen cats; they made this infernal row almost every night.”

I asked: “How long did you live in this place?”—“Eleven years, i.e., from my 12th to my 23rd year.” The patient is now 24! So she lived for eleven years, and actually until the year before, in a place where she was disturbed by caterwauling. As we have seen, the inhibition on the reminiscences about cats is so excessively strong that it leads to the greatest contradictions. It has to be pointed out that the patient’s tone, which was usually very courteous and unassuming, became irritable and aggressive during the analysis; a manifestation quite unusual for her. Simultaneously her face more and more assumed an expression of suffering; she thus showed the same expression that otherwise belongs to the illness-complex. Now I asked her whether she knew the meaning of the nightly caterwauling, which she indignantly denied; I probed but received a vehement denial. A 24-year-old girl of average intelligence who has had a cat of her own, and apart from this had ample opportunity to learn about the behaviour of cats, must surely know what the nightly gatherings mean. When she is hysterical, she perhaps does not know it with her *ego-complex* but surely with her *sexual complex*.[15] Now I explained to the patient that the caterwauling meant *mating*. This was followed by visible excitement; the patient did not answer, blushed and looked out of the window. With reference to the dreams, I told her that cats had a symbolical meaning; she would be given the interpretation later. If one dreams of cats or *dogs*, this always means something definite. On the following days the patient repeatedly asked for the meaning of the dream, which interested her.

[828] SECOND DREAM (Nov. 30). *"The whole room is full of mice, which are jumping all over the place and are making a great noise. The mice have an unusual appearance; they have bigger heads than ordinary mice, somewhat like rats, but they have big black ears; they also have peculiar glowing hot eyes."*

[829] *Result of the analysis:* The mice conceal the reminiscence of two dogs (male and female) that the patient often saw playing together. The patient has already observed how dogs jump at each other. She has also seen the dog stand up against a maid. This again is about mating.

Material: Superficially we notice in this dream that on the whole the situation of the last dream is repeated, only the cats have been replaced by mice which, however, do not seem to be proper mice. The "glowing hot" eyes seem to be a fragment of the fire dreams. I put the text of the dream to the patient again; she has nothing to add.

Associations to the mice: "I particularly noticed that all the mice jumped out of little wooden huts—(this essential piece of description had apparently been kept under an inhibition and therefore could not be produced until now).—The huts looked like dog-kennels.” Here we seem to be on a new track, because dogs do not appear in the dream. It is true that in the last analysis I drew the patient’s attention to dogs. The idea “dog” seems to be indicated indirectly in the dream (i.e., it is repressed). I therefore take “dog-kennel” as the starting point of the analysis.

Ideas relative to *dog-kennel:* “Surely, there are many dog-kennels —(indignant) I don’t know what you mean—there was nobody near us who had a dog—but one can see such dog-kennels everywhere—in gardens and courtyards—I cannot understand how you could suspect anything here—whatever could be behind it! For instance, *just behind our house there was a garden with a dog-kennel in it*. There were two dogs, two black ones, I think setters—perhaps a dog and a bitch; but the bitch was immediately removed—they often played together—they tore paper or pushed sticks about—or barked.” Then comes a complete resistance with vehement indignation; she does not want to hear anything more about the dogs. After much persuasion it comes out at last that she often saw the dog stand up against the maid when she went into the garden. That the dog mounted the bitch is vehemently denied. But we know already that there are certain things that the patient cannot say, because the inhibitions are far too strong. It can with the greatest probability be assumed that she has seen it; this can be conjectured not only from the way she tells the story, but also from the whole situation. I say: “But one can often see dogs jump on each other’s backs!” “Yes, I have often seen that in the street, but these two dogs did not do it.” I asked her what the jumping meant: she explained it was a game, she did not know any other meaning. She said the last sentence in an irritated voice. We have to make the same comment here as on the previous dream: it is inconceivable that she does not know the meaning. Here, however, we must again remember the influence of the sexual complex on the conscious perceptions of the ego.

The dream may be reconstructed in the following way:

The mice are cover-figures which, however, are penetrated by the elements of the cat dream at several points. *Mouse* is a current association to *cat*, the two words can thus substitute for each other in the dream (or in a state of reduced concentration!).[16]

The mice are as noisy as the cats were, also they are in the room and in greater number. The mice have larger heads; thus they are not really mice, but larger animals. They have large black ears, like the black setters which also have big black ears. The mice jump out of kennels. The analysis points to a very ambiguous situation, the interpretation of which should not be difficult; it is *mating* again, as in the previous dream. That the dog jumps up on the servant seems to be a subtle indication as to what sort of person the thought of sexual intercourse refers to. This indication was missing in the first dream. Perhaps one may express the hypothesis that the first analysis stimulated the patient's sexual complex, so that her own person appeared in the next dream. I would also point out that as, in the earlier blood and fire dreams, the entire room was always full of blood or fire, the room is now full of cats and mice. The analysis took place on December 1, after the third dream, which follows. I did not inform the patient of the analysis of the second dream, so that when she had the third dream she had no insight about the content of the second dream.

[830] THIRD DREAM (Dec. 1). *"She goes into a shop in the town to buy something. A big black dog that is very hungry comes along and jumps up on her, as if she could give him something to eat."*

[831] *Result of the analysis:* In this dream the patient clearly takes the place of the maid of the previous dream, thereby revealing that the *idea of mating* refers to her.

Material: The manifest form of the dream betrays the content in line with the analysis of the preceding dream.

The patient is now in the situation of the maid; this clearly throws light on the critical point which remained unexplained in yesterday's dream, yet in the form that the patient could not understand on the previous day. Had she understood this symbol, it would probably not have been used—like the cats, the significance of which had been explained to her. Associations to the "dog jumping up": First there are generalities as usual, excuses and blockages which I am not going to reproduce, so as not to go into too much detail. At last she again thinks of the scene with the maid and the dog. Our first thought when considering the dream was of course this scene, but it was different for the patient. She has to search for it at great length, as if it were a reminiscence that had long since faded away and been forgotten. This is because at first she has to push aside all the resistances attached to this recollection. We are free from such resistances. The same thing happens to her in the dream-analysis as happened in the association experiment, when she always had the same blockages at critical points, even after two or more repetitions, although one would actually expect that a reaction produced with so much effort would be more enduring than one without any special significance.

On the same day I carried out the analysis of her main symptoms (see below). During the following night she had a dream:

[832] FOURTH DREAM (Dec. 2). *"She is standing in the corridor of the Department and sees a tall black man coming along. He is leading someone down the corridor, but she does not see whether this person is a man or a woman."*

[833] *Result of the analysis:* The black dog becomes the black man, the scene is transferred to the Hospital. The black man is the disease-producing sexual complex that brought the patient to the mental hospital. She is trying to gratify her desire for love by falling in love with the doctor, but it is not to the purpose, since the doctor is already married.

Material: The manifest form of the dream reminds us of the dog scene, except that the big black dog has now become a big black man. The maid of the dog scene (the patient herself) has become blurred (the patient does not know whether it is a man or a woman). The patient herself does not appear to take any further part in the dream; we therefore have to look for her in a dream-figure, and may well presume that she is the indistinct figure.

Associations to the "black man": "The man comes from the front door, as if taking someone to the Department. He is dressed like a judge of a Vehmic court[17] (whom she had once seen at the theatre); he looks like a ghost, "like the black man whom I used to see when going off to sleep." I asked her whether it had frightened her: "No, I was not frightened of him—yet I was. I even wanted to retreat into a room out of fright, but a nurse called out: ‘Stop, this is forbidden! This room is already occupied.’ “There is apparently an inhibition attached to “fright.” We have now traced the “black man” of the *dream* back to the “black man” of the *vision*. The vision shows the man stretching out his hand to catch hold of her; this frightens her very much. The vision is a stereotyped complex-expression, like the blood and fire dreams; it is thus a rather rigid psychic product which it is not easy for the analyst to tackle. In fact, the analysis comes up against strong barriers here which the patient cannot break down. We therefore have to resort to conjecture. The black man who approaches her to catch hold of her is analogous to the hungry black dog that jumps up on her. The dog has a strong sexual background, which probably also belongs to the black man. The vision originated at a climax of the illness, when the patient was often thinking of death and was afraid she might even die as a result of her illness. As we indicated in the analysis of the associations, thoughts about death do not by any means exclude the sexual background; on the contrary, they can take the place of sexuality. As we have seen from the analysis of the associations and the analyses of the dreams so far, the patient is completely pervaded by a sexual complex. It is therefore most likely that the idea of intercourse is enacted in this dream as well. But let us leave this aspect for the time being and observe more closely the behaviour of the black man. At the height of the illness she is afraid she will die. Symbolically expressed: death is stretching his hand towards her, i.e., the illness will take her and lead her into the grave. The black man of the dream is leading an indistinct figure, who might represent the patient, into the mental hospital, and moreover to the same department where the patient is in actual fact. Thus the illness has not taken the patient to the grave but to the lunatic asylum.

The black man derives from the sexual dog, and the illness from the sexual complex.

To elucidate this sentence I beg to remind the reader of all the statements so far made: in the associations the clear and intensive activity of a sexual complex becomes obvious; in the dreams we found up to now nothing but metaphors for the sexual complex. At first there are the stereotyped blood and fire dreams, which are of a naïve symbolism. They say: “My blood is hot, I have strong sexual feelings of love.” The dreams speak of sexual intercourse. Her illness is clearly connected with menstruation. That much is also acceptable to the patient, that the illness has a connection with the first period. Everything we were able to find out so far speaks for the sexual origin of the illness. What the patient is yearning for is doubtless The Man. She wants the man but has the illness; as long as she is ill she cannot get married. Does she want to be ill? We know the will-to-be-ill of hysterics. They escape into illness for some reason; they want to be ill. This is a truth that almost forces itself on the observer. From the asthenic personality of the patient who, for no other obvious reason, breaks down in the simple association experiment, which does not require any effort, I could not help getting the impression that she did not make any effort whatsoever to react normally, i.e., to be healthy; on the contrary, she behaved in such a way that one could not help seeing how ill she was and how little interest she had in being healthy.

She needs the illness as an obstacle to prevent her getting married. So she has the choice between illness and man, therefore the choice between the joys of sexual love and the care and attention given to the sick child, which also has its advantages for a naïve female mentality. I had explained to her the previous day that she wanted to be ill because she was afraid of getting married and being healthy. The dream is the answer to it. I had already told her dozens of times: “You are escaping into the illness again; you must not do that, it is forbidden.” I said this to her each time she wanted to avoid telling me something unpleasant and disguised it by a headache and heat sensations. What does the dream say?

“But a nurse called: Stop, this is forbidden!” the nurse (thus my proxy) calls out in these words when the patient wants to take refuge in a room from fear of the black man (this part of the dream is, as its form shows, further protected by a special inhibition, so that it is produced only during the analysis). The fear of the sexual future and all its consequences is too great for the patient to decide to abandon her illness. She prefers to be ill, as she has been up to now, i.e., in actual fact to be nursed and pampered by her mother.

The dream, however, does not end with the presentation of this train of thought; it says, moreover, that the patient cannot retreat into the room, for it is already occupied. As the analysis shows, we assume that to take refuge in a room is a symbol for escaping into the illness, that therefore "room" means "illness." The patient is, however, in possession of her illness already, it therefore cannot be occupied by anyone else. But let us remember that "illness" is ambiguous. Her illness is the sexual complex, i.e., the repressed sexual feelings. The prohibition thus also says: It is forbidden to have sexual feelings, because something in the sexuality is already "occupied." Because of lack of time I had to interrupt the analysis at this point and to postpone it to the next day, when I intended to ask for information about which room it had been in the dream. On the following day I asked the patient at once which room it had been. She promptly replied: "Room No. 7." In order not to spoil anything, I asked the patient for the dreams of the previous night, before I began the analysis. She had dreamt again:

[834] FIFTH DREAM (Dec. 3). *"I was outside and stood next to Miss L. We both saw that a house was on fire. Suddenly a white figure emerged from behind the house; we both got scared and exclaimed simultaneously: 'Lord Jesus!'"*

[835] *Result of the analysis:* Here the black man has turned into a white figure; the burning house is the sexual complex. Miss L. is a patient who has a crush on the author. She was, like the patient, taken ill because of an erotic complex. The patient therefore expresses through this person that she has fallen in love with the author. Thus the patient substituted the tender relationship with her mother, which is damaging to her energy, by the erotic relation to the doctor.

Material: The form of the dream shows us that because of the dream interpretation the black man had to assume another disguise and changed to the white apparition which, however, played the same frightening role. The situation too is similar in that, as the patient starts to do something, she is suddenly prevented. In the burning house we suspect the *heat* of sexual feelings. A pointer for the analysis is, by analogy with previous ones, that part of the last dream that was not completed at yesterday's analysis; namely *Room No*. 7. Room No. 7 is occupied by Miss L., a patient of the same age as our patient. This gives us a new point of vantage regarding the previous dreams. In that dream the patient thought something like this: “I go into Miss L.’s room, I do the same as Miss L.” Particularly characteristic of Miss L., however, is the fact that she is in love with the writer—hopelessly, as the writer is already married. The patient therefore finds the “room” occupied in two senses: (1) Miss L. is already in love with the writer; therefore there is nothing left for her. (2) The writer is married; this precludes any tender emotion from the very start. In today’s dream the idea of yesterday’s is elaborated in more detail. In the dream the patient always does what Miss L. is doing. Thus she also watches the burning house. Therefore she also has a hot yearning or a burning love. The patient also knows that Miss L. was taken ill because of an unhappy love-affair. Here is a further very stimulating analogy! Therefore they both see how the white apparition, alias the black man, alias the illness, suddenly appears behind the fire of love and frightens them both, as love has made them both ill. Miss L. suffered from sudden depressive agitations, during which she behaved in an utterly despairing and senseless manner. The patient always was amazed at this and frequently stated with satisfaction that *she* was after all not so ill as to have to behave like that. I had also often told her (our patient) that if she had let herself go, she would have become even worse. Thus the patient could easily think, with her mild jealousy of Miss L., that Miss L. had let herself go more and therefore had become more severely ill. This is how “Room No. 7” was further determined. This point had not been explored in the former analysis; therefore we meet it again later on.

The content of this dream again throws light on that of the previous one in a peculiar way: The fear of the black man (sexual future) makes her escape into illness, which is, however, forbidden. Therefore the patient looks for a new way out: she does the same as Miss L., she falls in love with the doctor who can appreciate the complex and is a sexually harmless man; thus the dream finds a fortunate compromise. It replaces the love-giving but illness-producing mother by the healing but also sexually significant man. But there is a snag; the patient is poor and cannot stay at the clinic much longer, because she has not enough money.

Miss L., however, is very rich and can stay as long as she likes. Miss L. then can take her place and “occupy” the room.

This manoeuvre also led nowhere and therefore the idea behind it remained active.

When I tactfully explained the content of these dreams to the patient she made a sad disappointed face—apparently the explanation was too blunt—and said in a suffering tone: “Oh, if my mother knew the things that are dragged out of me here!”

This reaction is noteworthy, since her mother would probably be indifferent to shades of feeling in her daughter. The answer, however, excellently depicts the cooling down and turning away of the patient’s infantile sexual need for tenderness from the doctor and her reinsurance with the mother’s love, a clear indication that the compromise is not tenable and the patient cannot separate herself from her childlike relation to the mother.

[836] SIXTH DREAM (Dec. 6). *“My father is here and I am showing him the Institution by going through all the departments with him.”*

[837] *Result of the analysis:* The patient fulfils the wish to stay longer in treatment with the author, which she hopes will cure her.

Material: The patient states that this is only a fragment of a longer series of dreams which, however, she cannot remember. Even analysis cannot produce what is missing. It is not difficult to understand the dream; it represents an uncompleted piece of yesterday’s dream. The patient behaves in this dream as if the Institution is more or less her home. I had asked her occasionally whether her father never came to visit her, to which the patient said that she thought she was here for such a short time that it was not worth while for her father to make the journey. In the dream apparently a situation has arisen in which the visit was worthwhile all the same. So the patient can stay here for a very long time (as she actually wants to do). Besides which, the dream shows the patient in an unexpected position of authority. She has the master key which opens all the departments for her; this leads to the conclusion that she is enjoying the quite special confidence of the doctor. What this confidential relation to the doctor means is not difficult to guess.

[838] SEVENTH DREAM (Dec. 6, during the same night as the previous one). *"I am at home, Mother is sitting at the dinner table, you, Sir, opposite to her, and you are eating. Between Mother and you there is an empty chair. I want to sit down on this chair and eat too. But Mother has a hot flat-iron which she pushes towards me and that makes me get hot in the head. I tell Mother to put the iron away; she makes me feel hot with it so that I cannot eat. I too would like to eat with you both. At this you get up and shout at me that there is no need at all for me to eat now, I can just as well eat later."*

[839] *Result of the analysis:* The patient desires a sexual relationship with the author, for she hopes that in this way she may get free of the influence of the mother which contributes to her illness. But the author is married, so that this wish cannot be fulfilled. She must therefore remain ill.

Material: This dream too shows a transparent symbolism; we can interpret it without any difficulty with the help of the pointers in Dream IV. We have seen that in Dream IV the patient starts to make a compromise between the infantile relationship to the mother and the sexual relationship to the man. Here the author clearly takes the role of the "man." The animal symbolism had already been dropped in the latest dreams, as it had been dealt with and become too transparent. So she has to create other coitus symbols. The dream begins with the patient being at home. This is the main question now which she puts to me daily: "How will it work out at home? I am always afraid it will go wrong again at home!" What is dangerous at home is mainly the mother, who as the careful nurse of her youngest child and image has apparently contributed her share to the patient's hysteria. Thus at home the question again arises: "Shall I continue with the role of the sick child that needs nursing, or shall I, in accordance with the doctor's advice, entrust myself bravely to the sexual future?" She therefore stands between doctor and mother. The author is eating, she wants to eat with them, i.e., to do the same as the author. In what way can she do the same as the author? There is only one possibility, and that is the one that has already repeatedly been deliberated: to marry. She would like to sit in the chair next to the author, she would therefore like to sit beside him; this means nothing but that she relates to me in the sense of “husband.” Does “to eat” therefore mean the marital function? We know Freud’s principle of the displacement from below upwards. What happens to the mouth (in the dream, in hysteria, in schizophrenia) happens to the genitals. If one eats, one puts something into the mouth.

(A patient in the early stage of dementia once expressed her wish-delirium by saying that the man she desired as her bridegroom fed her with a spoon, which made her pregnant and she had a child.) So she wishes to enter into a sexual relationship with the doctor. But the mother makes her feel hot with the flat-iron, so she cannot sit down at the table, i.e., the mother brings back her illness (heat sensations in the head) and thus prevents her marriage. The fear that she may become worse again when she gets home is reflected here. Up to now the author has played a passive role, so that actually nobody but the mother stopped her from giving her love to the doctor. But now the author gets up and rejects her bluntly by forbidding her to “share the meal,” i.e., to attach sexual thoughts to him, and at the same time comforts her by referring her to the future, when she can get married. This passage refers to a talk that I had with the patient a few days before, in which I carefully indicated that the question of getting married would not be so difficult later on, once she was well again. From this content it appears that the patient is again concerned with the dream-situation of the occupied room, with some variation, but this is connected with the obviously deep impression made on her by my previous analysis, in which I ruthlessly destroyed her illusions. Through this refusal she sees herself thrown back on the mother, and with the mother she becomes ill, because the mother does not want her to get married (see below). I have hardly concluded the analysis with the patient, when she says, quite out of context: “I am reminded of a dream that I used to have very often. I always used to dream of worms, reddish and whitish ones, the floor and the whole room were full of them (just like the blood, the fire, the cats, etc.). Very often, too, it was as if a colossal worm was being drawn out of my mouth.” This dream in this context can be nothing but one of those penis dreams, so frequent in the normal as well as in the ill person (in dementia praecox, patients often have special neologisms for this such as snakes, the stalk of a lily, staff of life, etc.). The *mouth* again indicates the displacement from below upwards.

It is therefore not unlikely that interference with marriage by the mother is the hysterogenous basic experience. Moreover, a sexual trauma has to be expected because of the lively eroticism of the patient. Therefore I told the patient that I was not satisfied, there must exist another experience which she had not yet told me, and which was of particular importance. Perhaps it would be revealed to me by her dreams. Perhaps this experience has also a connection with her cleanliness compulsion. Then for eight days the patient cannot recall any dream, although she knows she has had vivid ones. During this time I tried, as always, to get her interested in some activity and repeatedly discussed with her whether she did not know of any chance anywhere of earning a little money. After eight days had elapsed she again remembered a dream.

[840] EIGHTH DREAM. *"I am at home and picking small coins up off the floor. I also find lovely stones, which I wash. I put the money and the stones on the kitchen-table and show them to my brothers."*

[841] *Result of the analysis:* The patient thinks of going home, she has made several good resolutions and particularly thinks that she will find a substitute for the impossible relationship to the doctor in her family, especially in her brothers. The background of the dream, however, remains uninterpreted.

Material: In this dream she has realized her future earning of money. A new feature, however, is "the lovely stones" which she washes (cleanliness compulsion?). She shows her brothers what she has washed on the kitchen-table, which is perhaps reminiscent of the dinner-table? The analysis yielded nothing but generalities; the strongest resistances were put up against any deeper penetration. What are the brothers doing at the kitchen-table, are they perhaps replacing the doctor at the dinner-table? I could not solve this question.

[842] NINTH DREAM (Dec. 12). *“I am going for a walk in Zurich, but it suddenly becomes the place where my home is. Outside a house I see a policeman standing, talking to a man whom I only see indistinctly. The policeman makes an extremely sad face and enters the house. Then suddenly Miss L. walks along the street with a terribly sad face. Then we are suddenly together in a room and are sitting at the dinner-table. Suddenly someone says that the house is on fire. Miss L. says: ‘Now I am getting into bed.’ I find this inconceivable and run out into the corridor, but there I am told there is no fire; it was therefore only a false alarm. Now I go in again and find myself at home in the kitchen with Mother, and two of my brothers are there too. A basket full of gorgeous apples is standing there. One of my brothers says: ‘This also is something for me.’”*

[843] *Result of the analysis:* The patient, like Miss L., is disappointed in her hope of love which, however, she understands with regard to Miss L., whose less good qualities she scornfully stresses. So she goes home, where she again enters into a suspiciously intimate relationship with one of her brothers.

Material: The general situation of the dream is a similar one to that of the seventh dream. It is again about being together at the dinner- or kitchen-table. In the first part of the dream there is a policeman with a terribly sad face. Immediately afterwards and quite suddenly, Miss L. turns up with the same attribute. The policeman enters a house, and this is immediately followed by the patient eating with Miss L. in a room. Miss L. and the policeman are apparently equivalent. How and why has Miss L. changed into a policeman? I ask the patient for conspicuous characteristics of Miss L. The patient finds in particular that Miss L. has such peculiar manners that she is only half a woman, almost a man, and she is also very thin. We have a long thin sausage in Switzerland which is called something like “dried-up policeman.”[18] This term is also used as a nickname for thin people. The patient thus indicates the less laudable aspects of Miss L. Why she does so is shown by the circumstance that the policeman speaks to a man whom the patient sees only indistinctly; if Miss L., however, speaks to a man, then in the dream it can be nobody but the author. It is therefore likely that the patient is again jealously stressing Miss L.’s feelings for the author, thence treating Miss L. very disdainfully. Then she sits with Miss L. at the dinner table. She is therefore in a sexual situation with her which, however, one must not think of as anything homosexual, as “dinner-table” in its sexual meaning has already been dealt with by the author; it would therefore be far too transparent. Here it probably only means: “I feel sexually as Miss L. does.” The fire-alarm that follows also indicates this.

The patient goes outside to look. Miss L., however, goes to bed, i.e., becomes sick with love. To understand this, we must know that Miss L. always went to bed when she was excited. At the beginning of the dream the patient humiliates her rival, then when the sexual situation (fire-alarm) comes up, Miss L. actually becomes ill and therefore completely harmless. So the rival has been put out of the way. But the patient hears it is only a false alarm: this is the disappointment (“the room is occupied,” “she cannot partake of the meal”). The author has spoiled her illusions, the transposition of her desire for love to the man has not succeeded, she therefore has to return to mother, where at least she finds an equivalent to the gratification of her need for love. Therefore the situation changes in the second part of the dream. The patient is suddenly at home with her mother in the kitchen instead of at the dinner-table. If only the relationship to the mother was concerned, there would be no need for the brothers. But two brothers are there as well and, as in the eighth dream, at the kitchen-table, but instead of the “lovely stones” a basket of “gorgeous apples” now stands there, and a brother says: “This also is something for me.” The dinner-table scene of the seventh dream, as well as the dinner-table scene of this dream with Miss L., can hardly be interpreted in other than a sexual sense: now we have a similarly constructed picture in immediate succession to the sexual scene in that “dinner-table” has been replaced by “kitchen.” In the first place the “gorgeous apples” look like the “lovely stones” on the kitchen-table, and secondly they are something edible (cf. Eve’s apple). This is something for the brother, he gets some of it. We have to keep in mind: in the first part of the dream a sexual wish is destroyed for the patient; the second part can hardly refer merely to the mother, sex must somehow play its part here. I now make her produce ideas about the “apples”: “I thought of the apples I saw at a fruiterer’s[19] yesterday. I was there with Mrs. Jung." So she was there with my wife; this could be a clue. But now the analysis comes to a halt and no further progress can be made. So I make a fresh start with the brother: "This was my brother who lives in Italy: he has often invited me to go to Italy and visit him."

Remember here R.25, Test VI.

Travel: The patient associated at this point: "A nice journey to Italy—honeymoon." This would, however, be nothing to do with the brother, and yet the apples are meant for him too. I would like to add here another short dream which the patient had right at the beginning of the treatment. She dreamed that I came into the room and she said to me: *Unfortunately the nuts could not be gathered yet, but she had a whole basket full of them at home*. In this dream the patient offers the fruit to me, nuts. Nuts are as hard as stones, one has to open them to be able to eat them. Remember the "lovely stones," the "gorgeous apples," which she now allocates to the brothers. What her erotic expectation originally promised me is for the brother now, she has turned away from me.

I think that here it becomes obvious that there is something about the brother that goes beyond a sibling relation. The brother's significance for the sister becomes suspect (cf. *to kiss/sister's kiss)*, and we cannot help having a strong feeling that here is something, sought for a long time, that would explain a lot, if we could be sure of it.[20] Some adventure of the time before puberty, in which the brother plays an impressive role, seems to be at the bottom here, a Freudian trauma. But the secret is well defended, and the analysis cannot gain access.

I told the patient quite casually of the content of the analysis, avoiding making any hints of a sexual nature. I wanted to avoid this because revealing the symbolism might make the next dream even more obscure. The inner development of the patient indicated in this dream, i.e., the turning away from the author, the abandoning of his point of view and the invalidating of his advice and teaching showed themselves (apart from an objective deterioration) in the significant fact that the patient now started again to dream of fire and blood; she "heard the *fire-alarm* every night."

The time of discharge now came nearer and nearer, and I hoped for a decisive dream, but the patient did not remember her dreams any more (except the fire dreams) apart from a single small fragment that did not tell us anything. On the morning of the day of her discharge I asked her, as usual, whether she had dreamt again. She said “Yes” but added quickly: “But I know already what the dream means, I noticed it at once. But I am not going to tell you; it is something from the past that I can only perhaps tell my mother.” I implored her repeatedly, but in vain; she insisted it was of such a nature that she could only tell it to her mother. At last I said, then it must be a very unpleasant sexual story! The patient did not reply to that but looked out of the window. I could not venture to press the point any further.

Thus our dream-analysis and the analysis of the illness as a whole remain incomplete, at a point which, however, appears clearly defined.

Summary of the Dream-Analyses

[844] Although actually none of the analyses was as complete as we could wish, and in particular the last one breaks off at an important point, we have yet gained through them a number of valuable clues. Above all we see that the dreams completely confirm the complex revealed by the association tests. The associations point to an intensive sexual complex, and the dreams are about nothing but the theme of mating. This makes us realize that the complexes that constellate the associations of waking life also constellate the dreams. We have the same blockages that turn up in the association experiment, in the dream analysis too. The analysis of the dream-images revealed the sexual complex, its transposition to the author, the disappointment and the patient’s reversion to the mother, and the resumption of a mysterious childhood relationship with the brother. The object of the next chapter is to show the sexual complex in the hysterical symptom and in the course of the illness.

III. The Hysterical Symptom

[845] It only remains now to apply our knowledge of the form and content of the sexual complex, gained in the two previous chapters, to the

symptoms of the illness. Let us start with the “St. Vitus’s dance.”

[846] According to the case history, as given by the patient, the St. Vitus’s dance suddenly started one day for reasons unknown. All questions about the reason are answered in the negative, and it seems to be impossible to get at the cause, because it is unknown to the patient. But we already know very well the resistances that stand in the way of the production of all complex-ideas. Hysterics have access to their psychic material only in so far as it refers to insignificant ideas; but where the complex is involved they are powerless. The complex does not belong entirely to the hierarchy of ideas contained in ego-consciousness; because of its strong emotional charge it is more or less autonomous (as is, after all, any strong affect) and forces the association in its direction, even if the ego-complex endeavours to think and act in its own interests. For this reason we cannot talk about “intimate” things with the same security and calm as of objective ones. The need to keep the “intimate” secret can become strengthened almost to the impossibility of producing it, as we have seen in the case described in “Psychoanalysis and Association Experiments.” If, therefore, we want to get information on “intimate” matters, i.e., on the complex in a hysteria, we can get it only by detours. Freud made a method of the detour; it is psychoanalysis. First we liberate general cover-ideas which stand in some associative (often symbolical) relation to the idea of the complex, and so we gradually approach the complex from different aspects. The method is basically the same as that used by a skilled examiner for a nervous candidate. The candidate cannot answer the special and direct question, he is too agitated; so the examiner first gets him to answer a number of quite general and easy questions, the emotional charge of which is not too great, and then the required answer comes quite spontaneously. Similarly, if I at once ask the patient for the cause of her St. Vitus’s dance, nothing will come of it; so first I make her answer harmless supplementary questions, and in this way learn the following:

She liked going to school, she also liked the teachers. Although she did not like all lessons equally she cannot, however, remember that she particularly disliked certain lessons, or that she particularly disliked certain teachers. She did not much like writing-lessons; she actually disliked this class. It was during the writing-lesson (in her second year at school) that her right hand first started twitching. Then the twitching became gradually stronger so that she could not write any more. She therefore had to miss the writing-lesson. Then the twitching started in the right leg too, so that soon she could no longer go to school at all. So the St. Vitus's dance gradually developed. She also remembers that she could not help crying "terribly" all the time and was afraid to go outside when it was raining, so that she frequently missed school for this reason as well. The St. Vitus's dance was sometimes more, sometimes less marked, so that sometimes she could go to school, sometimes stayed away. During her twelfth year, however, the illness became so violent that she had to give up school altogether.

[847] I think it emerges clearly from this narration that the patient was an extremely spoilt child who used every opportunity to keep herself away from school for the purpose of shirking the detested writing-lesson. The twitching in the arm conveniently began, which then ultimately served the purpose of making it completely impossible to go to school. The patient now also admits that she could have suppressed the twitching then if she had tried. *But it suited her to be ill*. The uncertainty with which the patient speaks of her feelings concerning her school reminiscences at the beginning of the analysis seems to me particularly instructive. First it seems to her that she liked going to school, then there are expressions of the feeling that it was after all not quite like that, and then comes the exact opposite, which coincides with the fact. This inconsistent way of presentation is actually a method of the patient (see the previous analyses). There is no indication that the patient is aware of the inconsistency at the moment; on the contrary, it seems that whatever she says at any given moment she absolutely believes. The school-complex, that well-known feature of all asthenic children, here leads to the formation of a hysterical symptom. The existence of an automatism understandably provides a suitable *locus minoris resistentiae*, from which further automatisms can develop if the situation demands it.

The day after this analysis the feeling-tones had changed again, the patient alleged she could not say she disliked going to school, she quite liked it. School never made much impression on her. She was much more occupied with other experiences, such as that once a schoolmistress had vehemently scolded her. So we have the same uncertainty and inconsistency here again.

[848] During her twelfth year the St. Vitus's dance grew worse. The twelfth year seems (according to the analysis) also to be the year from the recollection of which the sexual cat dream emerged. During the twelfth year the first puberty feelings become apparent in many girls and they begin to be interested in sexual secrets. But her twelfth year has yet another significance for the patient. I made the patient associate to the complex of the mother; the result was as follows:

A lot comes to her mind here—(after a long pause)—because Mother is also ill, and yet is so content and cheerful; if only she could also be like that. Mother always said her osteomalacia came from being married. But she had been taken ill 28 years ago; now the disease is curable, so the doctors say.

This remark made me ask: "Has this any significance for her?" None, she could not imagine at all what it might mean to her—she has never thought about it. I commented that the thought that she might have inherited a disposition to such an illness would be possible after all. She was never afraid of that, she would have got married in spite of it. I said that such a fear may perhaps have arisen in her at the time of the first period. "This is not possible, because my mother told me long before that, when I was *twelve years* old, that I must not get married, because then I would get the same illness."

[849] We may conjecture from this remark that during her twelfth year discussions of far-reaching sexual importance took place, which must have made a strong impression on the patient's fantasy, judging from the strength of the resistance with which she tries to prevent the elucidation of this point. In any case, during the twelfth year we find one of the first components of the sexual complex. At the time of the first period she was faced with two complexes, one associated with a fully developed automatism, the other with the sexual feelings. The possibility of converting this decisive experience into a hysterical symptom is thus given, but not the necessity for it, because the impossibility of marriage

appears by itself insufficient. We must also postulate the existence of an event that prepared the way for repressing the sexual complex, i.e., a sexual event of childhood. Here the sexual trauma, which the dreams seem to indicate, would fit in.

[850] With menstruation a new form of existence sets in, the sexual one. It is therefore not surprising if the school-complex is replaced by the sexual complex, though only outwardly; as we have seen, it is still present in the associations, it is still an open wound which is above all sustained by self-reproaches. That the school-complex, i.e., the St. Vitus's dance, potentially still exists is expressed in the following way: The patient once had a particularly bad day. She described the heat sensations as intolerable; while she was speaking her right arm twitched from time to time, then the left one too. I drew her attention to these movements, then her legs also began to twitch slightly, and she said: "I can only restrain myself with an effort from hitting out as I used to do. I feel the greatest temptation to do so!" We can see that the old automatisms are again ready to break through at any moment when her energy is completely exhausted (this confirms Janet's doctrine that each *abaissement du niveau mental* is accompanied by a flare-up of the automatisms). The onset of menstruation stimulates the development of the present complaints, heat sensations in the head and neck, a sensation as if all the blood is in the head, a temperature of 104°. Hands, feet, and body are cold. Simultaneously there are obsessive chains of ideas: she is constantly compelled to imagine that she is bleeding from the nose, from all apertures of the head, and that the clots that were discharged during the first period are in the head; she always wishes she could just once bleed enough from the head to fill a whole basin.

[851] This strange symptom-complex without any doubt refers to the period: it is none other than a "displacement from below upwards" (Freud). The mechanism of displacement is operative in the patient; we have already found it in the dream-analyses in a form that can hardly be mistaken. The heat (blood and fire in the dream) is probably the sexual heat appearing with the period. For many months the period has ceased, after being rather irregular; besides this there is an obvious meteorism and a posture that makes the abdomen protrude even more. These are,

according to Freud, symptoms of pseudo-pregnancy, an assumption that the psychological experience supports; where there is a complex of erotic expectancy in a young girl, the child plays a marked role in associations and dreams.[21] It will be remembered that this is in fact so in the associations of our patient. Furthermore, for the patient, pregnancy points to the danger of osteomalacia, which is bound to be strongly repressed. I am, however, unable to bring any positive evidence for Freud's conception.

[852] The following symptomic acts probably also originate from the repression of the sexual feelings:

1. the constant craving to cool down;
2. the cold washes;
3. the horror of meat in any form;
4. the inability to sit still;
5. a liking for indoor gymnastics while otherwise avoiding any physically strenuous occupations.

[853] These symptomatic acts exactly correspond to the hygienic precepts against states of sexual excitement given in popular text-books.

[854] Positive evidence for the repression of the sexual feelings is the consistent and obstinate evading of all sexual questions. As soon as the inquiry touches anything sexual, there is a barrier, and then one is usually held up by insurmountable obstacles. For theoretical reasons I made sure by appropriate questions that the patient was thoroughly informed about all the facts of sex, but she was unable to tell me where she knew all this from; she stubbornly denied having ever read anything about it or heard anything about it from anyone. She just knew it. Only towards the end of the treatment did the patient confess during the analysis, after protracted blocking, that a girl friend had enlightened her, when she was twelve years old. This too shows how strong the barriers are that guard the sexual secret.

[855] I need not go any further into the visions; they have already found their interpretation during the dream-analyses.

[856] The improvement moved at a slow pace, with frequent relapses. The energy visibly increased, so that the patient’s vigour gradually extended to four and five o’clock in the afternoon (originally it had already been used up by 10 a.m.!). She was again able to read without any interruptions and to do some needlework. But the heat sensations remained, only their intensity seemed less, and during the third month of the treatment the patient stopped telling me about them. She only wondered why she recently has such frequent depressions, the cause of which she could not understand (originally when there was something unpleasant, she never mentioned depression, only exaggerated heat sensations!). To my assistant, a lady doctor, however, the patient spoke of her heat sensations as before. After the dream of the dinner-table, when I had told her about her relationship with me, the earlier expressions were soon resumed, when talking to me as well. In the dream she heard the fire-alarm, and several times, particularly during the last week of her stay here, the black man, who had disappeared after he had first been interpreted, came back too. The dream-analyses show how this relapse can be explained. The patient was unable to reveal her innermost secret; the sexual compromise with myself had failed (apparently she could not find anything in me, apart from the sexual aspect, that would have been so valuable to her that she could have separated herself from her role as an invalid). As she was unable to separate herself from her secret, she had to cling to the heat sensations because of their repressive function, and so she came to resume the former symptoms and appropriate terminology, in this way demonstrating that my interpretations had been wrong; because she could not admit to herself that I was right, since that would have made the genuineness of her illness questionable.

[857] About a month after the discharge her family doctor wrote to me that she was just as bad as before and that she now grumbled about the hospital and the doctor, with indications that the doctor had only tried to find opportunities to make morally dangerous conversation with her. Thus the sick personality, i.e., the sexual complex, entrenches itself behind aggressive defence-mechanisms; it discredits the moral personality of the doctor as much as possible, in order to invalidate the information supplied to the normal part of the mind. In this way the

automatism of the illness secures itself a free road to unimpeded development, because each complex strives to live itself out unimpeded.

SUMMARY

[858] The complex revealed in the associations is the root of the dreams and of the hysterical symptoms.

[859] The interferences that the complex causes in the association experiment are none other than resistances in psychoanalysis, as described by Freud.

[860] The mechanisms of repression are the same in the association experiment as in the dream and in the hysterical symptom.

[861] The complex has an abnormal autonomy in hysteria and a tendency to an active separate existence, which reduces and replaces the constellating power of the ego-complex. In this way a new morbid personality is gradually created, the inclinations, judgments, and resolutions of which move only in the direction of the will to be ill. This second personality devours what is left of the normal ego and forces it into the role of a secondary (oppressed) complex.

[862] A purposive treatment of hysteria must therefore strengthen what has remained of the normal ego, and this is best achieved by introducing some new complex that liberates the ego from domination by the complex of the illness.

THE PSYCHOPATHOLOGICAL SIGNIFICANCE OF THE ASSOCIATION EXPERIMENT[1]

[863] Although there is more interest in psychology as a subject nowadays among non-psychologists than there was a few decades ago, nonetheless the relative youth of experimental psychology does mean that in this sphere little has as yet been clarified, and there is a good deal of controversy over many aspects of the subject. What is more, psychology is still a hybrid, inasmuch as the subject of experimental psychology is still in many institutions a very poor relation of philosophical psychology. The dogmatic nature of the latter is to blame for the manifold misunderstandings between the two kinds of psychologist. One wants to make psychology a creed, the other a science. Understandably these entirely divergent tendencies are in conflict with and hinder each other. This opposition makes itself felt most disagreeably in the field of nomenclature. The same words and concepts mean one thing with one writer and something quite different with another. So long as it is a matter of dogmas and axioms, which owe their existence to the *petitio* principle, one cannot hope for clarity, for each dogma entails a certain obscurity, as is well known. We are, therefore waiting for enlightenment from experimental psychology which, it is true, is still in its infancy yet can already look back on a rich harvest from the work in this field.

[864] Psychopathology too has had to suffer for years from the same opposition. First, it had, with difficulty, to free itself from philosophical ideas, only to become subjected to rigid schematic anatomical notions which nowadays are still firmly fixed in many minds. It is only comparatively recently that we have the beginnings of an experimental psychopathology that has recovered from its birth-pangs. For this achievement we owe our gratitude to the alienists; first of all to the eminent psychiatrist Kraepelin, the pupil of Wilhelm Wundt, and secondly to the psychiatrist Sommer. Kraepelin has taken over a series of fundamental ideas and methods from Wundt's school and with these attempted to pave the way to an experimental science of the sick mind.

Under his direction a large number of important papers[2] have been published that will provide a source of stimulating ideas and valuable methods for many years to come, even if the results of certain individual works are dubious or are, at least for the time being, of purely academic interest. The principal subjects of Kraepelin's research are mental ability, the influence of fatigue, drugs, and alcohol on simple psychic functions, fatigue and recovery, perception, etc.

[865] This research is mostly concerned with the experimental demonstration of various influences on the mind of a normal person. The real value of Kraepelin's work, however, lies in opening up various new prospects in the field of psychopathology.

[866] In addition to the papers on fatigue, Aschaffenburg's work on associations is particularly important in this context.[3]

[867] Before we go any further into the content of Aschaffenburg's work, certain matters of a general nature must be discussed.

[868] The ancients were already aware that the flow of our images and ideas is not entirely erratic; we find suggestions of laws of association in Plato and Aristotle,[4] the validity of which is still recognized today. The laws of simultaneity, sequence, similarity, and contrast are also the basis of Wundt's laws of association. Wherever in Nature there is a regular sequence of events the experiment can be applied. Thus experiments can also be made on the process of association, however complicated and difficult to follow this may be. After Galton's first tentative experiments,[5] Wundt and his group were the first to make systematic investigations[6] into association processes. The method of the experiment is extraordinarily simple; the experimenter calls out a word to the subject, who then says what is immediately called to mind by the stimulus-word. The experiment is thus similar to any other in physiology in which we subject a living object to an adequate stimulus, as for example the application of electrical stimuli to various parts of the nervous system, light to the eye and acoustic stimuli to the ear. In the same way with the stimulus-word we are applying a psychical stimulus to the psychical organ. We introduce an image to the consciousness of the subject, and are

given whatever further image is brought by this to his mind. We can thus quickly obtain a large number of connected images or associations. From the material thus obtained we can establish, by comparison with that from other subjects, that this or that particular stimulus will give a particular reaction. So we possess a means of investigating the law of association. The "law of association"! That sounds highly academic, and no one with knowledge of philosophy would hesitate to admit the possibility of such laws. However, the word "law" implies necessity and thus, applied to the experiment, it means that the stimulus-image must necessarily cause this or that particular association. The experiment would thus acquire the nature of something inexorable and causally inevitable. The subject must inevitably associate the appropriate image to a particular stimulus, just as the nervous system, when given a stimulus at one point, *ceteris paribus*, always causes contraction of the same muscle. If we recognize the necessity of laws of association, we must say that the subject has surrendered completely to the experiment because he must necessarily have that thought which is associated with the particular stimulus. This involves the idea of determinism. Not everyone however, will go so far with us. There are still many educated people today who, on the ground of idealism and for other reasons, believe in the freedom of the will. Consequently these people must deny the necessity of the law of association, and resolve interconnection of ideas into a number of fortuitous events. They must assert that the experiment indicated is open to the wildest chance; that a person can not only say, but also think, whatever he wants to; that, from hundreds of things that occur to him, he can choose now one and now another according to his taste or present mood; that he is not obliged to think in terms of similarity or simultaneity, etc. These are the usual objections. The same objections are raised by serious-minded people to determinism. They maintain, in all seriousness, that man is capable of choosing from among his various motives before the act of will occurs. Does he also choose from among the motives of the motives, and the grandfathers and great-grandfathers of the motives? And what does he do with those motives which do not enter his conscious mind?[7] Or do the motives perhaps come to the surface from the transcendental sphere as an incomprehensible act of the

Creator? If man wished to select from among his motives, he would have to spend years before he moved a finger in order to trace back to the mists of his childhood the entire series involved and consider all of them: he would never finish. In this process he would again and again be dependent on the results of all previous motives or *associations* to express himself with greater clarity. As you can see, it is *a priori* easy to refute the objection based on the principle of chance in psychical occurrences if the opposition is not intent on raising sophistical difficulties.

[869] In principle, therefore, it must be accepted that association is a necessary sequence following certain laws. Hence an association experiment in which chance appears to have an absolutely free hand takes on the dignity and conclusiveness of any other scientific experiment. Chance, by definition, does not allow of any rules, but does permit necessary occurrences. A rule means a restriction, a limitation of the occurrence, which must empirically be capable of proof. In the same way, too, the multiplicity of possible associations, which to the layman appears inexhaustible, must empirically be limited to a certain extent.

[870] This brings us back to Aschaffenburg’s experiments.

[871] The results of his investigation provide us with considerable insight into the vast difficulties of a huge subject. The most difficult of all is in fact the discovery of a law. From what points of view must the disconcerting profusion of thousands of associations be classified in order to obtain even a superficial impression of the whole? When one looks at the innumerable individual reactions one almost despairs of finding a foothold in the wild chaos. Wilhelm Wundt helped himself by means of certain logical principles of classification, based on the laws of simultaneity and similitude which have come down to us from classical times. Thus at least logical clues were obtained, although neither Wundt nor any of his pupils imagined that they could exhaust all the possibilities. Aschaffenburg and Kraepelin built further on the same foundations. They made one essential distinction: between internal and external associations. The following associations:

human being	boy

attack	defence
table	furniture

are internal associations, i.e., pairs in which the meaning or conceptual content of the words is the essential connecting link.

[872] On the other hand, associations such as:

knife	trousers-pocket
water	fish
plant	pot

are external associations, i.e., the connecting link is not the intrinsic sense or meaning but an external contingency. One particular form of this external connection is the catch-phrase; as such phrases readily come to mind they are especially frequent in this experiment. For instance, the following associations, as purely verbal connections, are to be considered as external:

time	and tide
whisper	sweet nothings
stick	in-the-mud
die	is cast

[873] Among external associations Aschaffenburg includes all current word-sequences.

[874] Apart from the internal and external associations there is often also the case of a word merely suggesting another having a similar sound:

part	heart
cow	plough
rabbit	habit

These have been called sound associations.

[875] In spite of the tremendous efforts made by various research workers, we have still not yet succeeded in finding a method of classification that is in principle entirely satisfactory. In any case, the present method suffices for solving many problems in association research.

[876] One of Aschaffenburg's predecessors in the field of association research, the well-known psychologist Münsterberg[8] (now in America), believed he had found that the existence of three different intellectual types was proved by his experiments. He found that among a limited number of subjects there were some who reacted mainly in terms of super-ordination, others in terms of co-ordination, and others in terms of sub-ordination. Aschaffenburg, however, with a much more reliable method, found nothing of the kind.

[877] The hope of finding categories governing association was thus premature. No regularity was to be detected *prima vista*. One subject would make many internal associations, another many external ones; one would make no sound reactions and another several. No one could account for the differences.

[878] At this stage, however, Kraepelin and Aschaffenburg made one fundamentally important step forward. They altered the psychical condition of the subject in the most unequivocal manner; the subjects of the experiments were deliberately made as tired as possible in the following way: each of them would, after a full day's work at his usual profession, be given a series of association tests at intervals from eight o'clock in the evening to eight in the morning, the pauses being given to some other form of mental work. During the night the subjects were given nothing to eat.

[879] By this means a state of intense fatigue was created.

[880] One quite constant phenomenon now became evident in the associations of the various subjects; there was a decrease in the number of internal associations, and an increase in the external variety, and especially in the sound associations, i.e., associations with other words. Semantic connections grow weaker with increasing tiredness and are replaced by external and superficial connecting links. It can thus be stated that the valency of associations decreases with increased tiredness.

[881] Thus we have the first important rule about the faculty of association. Fatigue obliterates individual differences and drives the act of association in a particular direction. Besides this, Aschaffenburg also discovered that

in one of his subjects who was suffering from a severe attack of influenza, the associations were similarly affected. So the special disposition of the brain caused by fever also has an adverse effect on the value of association tests in that mainly sound associations are produced.

[882] These positive results, which far surpassed anything else that had hitherto been accomplished in the field of association research, provided Aschaffenburg with the link to the subject-matter of psychopathology. Clinical observations had long since established that in a certain mental illness, known as *mania*, a mode of association is prevalent that is similar to that found by Aschaffenburg in fatigue, i.e., the connections and sound associations were mainly superficial. The illness is characterized by a predominantly cheerful mood, distractability, and motor agitation, which are expressed in ceaseless compulsive activity. When we analyze the state of extreme fatigue, it is easy to find similar elements there. One has only to observe one's own state after a strenuous mountaineering expedition to be able to diagnose without difficulty an unaccountable superficial gaiety and a state of motor agitation, shown in countless irrelevant movements of the arms and legs. Sound associations, too, are easily seen in the jokes current among parties in mountaineering-club huts. Most of these are of the order of the pun, i.e., the onomatopoeic joke par excellence. Aschaffenburg believed that the common factor in these circumstances was *motor agitation*, and therefore attributed the cause of sound associations to this. In this, however, I think he was in error. In our hospital we have conducted systematic research[9] into associations for several years past and have obtained results that allowed of another interpretation. When a longish series of associations, say two hundred, is given to a subject, he will, without really becoming tired, soon find the process boring, and then he will not pay so much attention as at the beginning. For this reason we have separated the first hundred from the second in our classifications and have found that in all cases where the subject had become bored there is a clear decrease in internal associations and a proportionate increase in external and sound associations. This observation made us think that the cause of sound associations is not so much muscular stimulation, which is absent in normal boredom, but a lack of *attention*. We have been able to confirm

this interpretation on the basis of numerous experiments in which the subject's attention has been methodically distracted.[10] Furthermore, we found an increase in the proportion of sound associations with subjects whose ability to concentrate had been weakened by a recent affect, with people in a somnolent state, and in addition with psychotics whenever their capacity for concentration is reduced. Kraepelin's school have also shown a levelling down of associations in cases of acute alcoholic poisoning. Aschaffenburg found the same thing in feverish patients. *It can therefore be said that the more the attention of the patient decreases, the more the external and sound associations increase*.

[883] As you can already see from its numerous connections with altered psychical conditions, this empirically discovered law of association has, of course, great importance for the understanding of psychopathological states; in which, as is well known, one of the principle psychic functions, *the ability to concentrate*, is very frequently paralyzed or disturbed. In certain borderline cases between mental health and psychical disorder the experiment has already been of valuable service to us.

[884] Our knowledge of factors governing association is, however, not exhausted with the statement that the seemingly unrestricted association depends to a large extent on the subject's attentiveness. Research into the associations of a large number of educated and uneducated subjects has enabled us to establish that *on average* the uneducated gave internal associations more often than the educated.[11] This apparent paradox can be explained as follows.

[885] Educated people are used to dealing with words out of any context (as in grammatical studies, dictionaries, etc.). Thus when we call out a word to an educated man, it means no more to him than just a word. An uneducated person, on the other hand, is only accustomed to hear words in a sentence, where they always have a definite meaning. If we call a word out to an uneducated person, he always constructs something like a sentence round it. He understands the word as a question: hence the tendency of uneducated subjects to react with whole sentences or by the use of higher categories. Thus for instance the educated man will react to *table* with *table-cloth* to *chair* with *chair-leg*, whereas the uneducated

man will react to the word *table* with *furniture*, and *chair* with *for sitting on*. The educated person finds it easy to grasp the experiment, while it costs the uneducated one an effort to do with words called out to him something different from what he is used to in his daily life. It therefore also happens that the uneducated are inclined to apply adjectives to themselves, particularly when they appear to express a judgment or anything of that kind, e.g., in the case of the word *stupid*. The degree of effort needed for concentration varies according to the subject's grasp of the experiment. This effort is obviously often greater in the uneducated than in the educated, and this naturally has some bearing on the valencies of the associations. With very uneducated and mentally defective[12] subjects, the reactions assume the character of definitions that frequently seem clumsy and comical, e.g.:

singing	consists of notes and hymn-books
strolling	when you go forward on your feet for a Sunday pint

[886] From our approximately 150 normal subjects, who provided a stock of over 35,000 associations, it can be seen that there is not an infinite variety of modes of association, but only a limited number of types, which I do not propose to describe to you; it would lead us too far afield. I will mention only one type; there are people who from the very start react with an extraordinarily large number of predicates. One can make the objection that this particular incidence can be very easily attributed to chance. We have, however, been able to demonstrate that whole families associate in the same way, without any one member being aware of the reactions of the others. This fact indicates that the type cannot be accidental but must be due to causes that at present still escape our knowledge.[13]

[887] As you can see, free choice does not play any part in the process of association. There are, however, certain rules: it depends on the momentary state of our attentiveness, our educational level, and the type of our family or other personal circumstances. You have perhaps already noticed that these three rules correspond to important criteria of personality; in other words, our personality (which, as is well known, one

knows least of all) plays a decisive role in the determination of the whys and wherefores of our associations. *One associates according to what one is*, or, as the psychiatrist Weygandt not long ago appropriately said: “Tell me how you associate and I’ll tell you who you are.” This is no empty statement. I will briefly outline the evidence for it:

[888] In the association experiment we measure time with a stopwatch to one-fifth of a second, from the moment the stimulus-word is called out to the moment the reaction is given. The interval of time taken we call the *reaction-time*. I will not bore you with an enumeration of the differing time-values. The assurance that the values fluctuate within a very wide range should suffice.

[889] As in the classification of associations, one should not lose heart in one’s attempt to evaluate seemingly fortuitous time-variations, since *a priori* one can hardly imagine that each of these variations has a particular significance. It is true that on closer examination we see that the internal associations, particularly reactions to abstract stimulus-words, on the whole require a longer time than the external associations. That, however, means very little—the differences are usually only fractions of seconds—beside the very much longer times that are often found with the simplest of associations. Here the time-differences can frequently be as much as twenty or thirty seconds without there being at first any indication of the reason for these variations. The subjects also cannot usually give any precise information about this. One gradually becomes accustomed to this chaos. We know from the research of Ziehen[14] and of Mayer and Orth[15] that it is particularly the associations that awaken memories of an unpleasant nature that take a long time. Thus, for example, A will take 0.8 seconds to react to *house* with *roof:* B gives the same reaction but takes 20 seconds. If we ask subject B whether, on hearing *house*, anything unpleasant crossed his mind, he tells us (for instance) that his house was recently burned down, which frightened him very much. Subject A, who had reacted in 0.8 seconds, has nothing special to report.

[890] Here we have an idea charged with an unpleasant emotional tone associated with the stimulus-word and causing a lengthening of the

reaction-time. Supposing that in this case B is a cultured person with the ability to analyze himself psychologically, and is prepared to offer up the knowledge of his deepest secrets, then we can pause after every reaction that takes longer than the average and ask what memory lies at the root of it.[16] We will assume further that the subject is able to give the desired explanation for each long reaction-time. When we have thus gone over one hundred reactions and analyzed them, we find that in many places where much time was taken it is not always fresh memories that are awakened but that one memory, e.g., that of a house that was burned down, caused a whole series of long reaction-times. This memory is reflected in the reactions to the following series of stimulus-words: *burn-fire-water-window—smoke-rescue-frightful—red*-etc.

[891] These varying stimulus-words conjured up a certain scene, a particular picture from the mass of memories. The memory consists of a large number of single images; we therefore refer to it as a *complex-image.*[17] The complex of these images is held together by a particular *emotional tone*, that is, by the *affect of terror*, the vibrations of which can continue gently for weeks or months and keep the image of terror fresh and vivid for that length of time. During the day work and other interests predominate, but from time to time these complexes make themselves felt through a faint and hardly recognizable unease or through slight feelings of anxiety, which seem to be unaccountable; at night they intrude into our dreams in a form the symbolism of which may be more or less pronounced.

[892] There are other emotional complexes similar to the complex of the memory of the fire; one is concerned with losing large sums of money, and another with somewhat unfortunate family relationships. These three complexes all have the same effect on reactions; they cause longer reaction-times and certain other disturbances, all of which I cannot now enumerate.

[893] If we spread out our psychological booty in front of the subject, he will be amazed that we have been able to build up, as it were, a precise inventory of his present psychological condition. In this way it appears that everything that occupies the mind of the subject is expressed in his

associations. In any case, all the most important individual *complex-images* are met with. Our subject admits further that at the time of the reaction he hardly ever had the feeling that the stimulus-word had any connection with this or that memory. Only when we asked him did it occur to him how he had arrived at that particular reaction. Contrary to his expectations, the subject had as it were offered in his reactions a psychological snapshot of his mind.

[894] We have been able to demonstrate fully this significant fact, the importance of which everyone psychologically oriented can easily gather, in hundreds of individual tests. It is, however, one of those not at all obvious facts that everyone doubts until he has convinced himself of its truth by conducting the experiment himself.

[895] Thus we found a further and in my opinion the most important factor determining associations. We can see, from the fact that in the few seconds of the reaction we do not choose something fortuitous but unconsciously take an item from our memories, that our reactions, far from being the result of a free choice, are predetermined to the smallest detail by our complexes. The occurrences of everyday life are nothing but association experiments on a major scale; the things outside us are the stimulus-words to which we react according to what we are and have become, and never in any other way. No one can get out of his own skin. We act as our psychological past, i.e., as our cerebral organization dictates. For this reason we are bound to expose ourselves in the association experiment in exactly the same way as we do in our handwriting.

[896] You can see that in this strongly forged chain there is no gap where free choice or free will can break through. So you may believe me when I say that recognition of this fact is of great value in the investigation of mental illness.

[897] Most cases of mental illness are, however, a matter of far-reaching change of personality. The association test at least paves the way for experimental research towards the discovery of the secrets of the sick mind.

[898] Before we go into this new application of the association experiment, we must say a few words about the manifold difficulties that stand in the way of the experiment even with normal subjects.

[899] We have been assuming that our subject is a man of excellent education, intellectually unbiased, and able to think objectively about his own feelings. In such a case, analysis will not be difficult. But if we were to take as subject a sensitive woman, who does not know us, the analysis would be considerably more difficult. Everyone is, above all, anxious to preserve certain secrets, particularly of a sexual nature, and will not disclose them at any price. It is here that from the very beginning the experimenter finds a significant and almost insurmountable obstacle in his endeavours to analyze. Then there are certain peculiarities of human consciousness that aid concealment and can make analysis extraordinarily difficult. I shall try to sketch these characteristics for you briefly.

[900] We have all of us at one time or another experienced something really unpleasant, which has subsequently haunted us for a long time. The natural reaction to this was that we made an effort to forget this black spot, to repress it, in that we quite deliberately did not think about it. And eventually we succeeded in not thinking about it any more. We have forgotten. In associations, however, this black spot reveals itself, and the long reaction-times caused by it show that the vibrations of the former affect are still there. In analysis we have at first some trouble in thinking of the critical point, and the more unpleasant it was the longer it takes us to get back to it. All kinds of other memories will come to mind first, but finally the old story will come up, and we can again feel slight vibrations of the old affect. Now there are people, lots of them, who cannot recollect the critical event at all; they have forgotten it. They have repressed the unpleasant experience so forcefully that it can no longer be revived. Very often, too, the inability to remember looks like a wish not to remember, i.e., the subject cannot will himself to think about it.[18]

[901] Our question remains unanswered. Many experiments have been wrecked on this shoal. Nonetheless the situation is not hopeless. In the last resort one can hypnotize the subject, and then one sees why he could

not think back. The critical incident is *so* unpleasant that one understands immediately why he did not wish to be reminded of it. In the more serious cases of hysteria this inability to remember is in fact the rule.[19] In these cases the complex is stronger than the conscious will and drives the subject in such a way that he cannot will himself to remember. The complex plays the part of a second and stronger personality, to which ego-consciousness is subjected. In these experiments we are shown the power of feeling-toned memories from which so many sensitive people suffer.

[902] The inability to remember in its various forms is the principal obstacle to analysis. We shall not go into a series of lesser hindrances.

[903] The objection may be made to analysis that one suggests something to the subject that is not in his mind. In my opinion, however, much too much has been attributed to suggestion. If suggestion were something better known and if so many superstitious meanings did not surround it, this could not then be maintained. It is quite impossible to suggest to a subject by means of a few well-oriented questions all his individual concrete experiences, with all the facets that they have in real life. A subject who lets himself have some experience suggested to him by a clumsy experimenter that he did not really have is a person who had previously had all sorts of phantasms in his mind. A psychologist, i.e., one experienced in the workings of the human mind, will not fall into this trap. He who understands the experiment properly will no longer be afraid of the unknown quantity of suggestion.

[904] So far as the content of complexes found among normal subjects is concerned, the subjects fall naturally into two groups: men and women.

[905] To take the women first, their complexes are of a simpler nature and are usually easily recognizable. The woman's complex is, in essence, usually of an erotic nature (and I am using the word "erotic" in the noble literary sense as opposed to the medical). It is concerned with love, even in apparently intellectual women, and is often particularly intense in the latter, although it is only revealed in a negative way to the outside world. No woman who thinks scientifically will take amiss my revelation of this fact. It is as natural and undeniable as the physical sexual process, the

existence of which is, it is true, kept secret but never denied. In unmarried women the complex is concerned with the remembrance of past erotic complexes or the expectation of future experiences. Among the secondary complexes, we find most frequently social questions, such as status and earning a living; in general these are clearly linked with the erotic expectation of the man, upon whose arrival the woman's social problem is usually resolved. In the third place come difficult family relations in the parents' home. Married women show complexes especially concerning pregnancy and children, then those connected with relations with the husband, and lastly social difficulties and domestic worries. Old erotic complexes strikingly often play a large part in the very great number of not quite happy marriages, in that they concern memories of previous lovers or at least hopes of this kind. It is mostly a case of the man she should really have chosen but did not marry.

[906] In men the erotic complex is not nearly so much in the foreground as in women. It is perhaps on the same level as that of ambition, or striving for physical, intellectual, or financial power. Money usually plays the leading part. The differences between married and unmarried men are not great. In men's associations traces of the social battle show up much more clearly than in women's. Complexes in them are not nearly so easy to reduce to a common denominator as those in women, which are almost all attributable to their erotic life. Nonetheless there are men too in whom the erotic complex is all-pervasive; the exception, however, proves the rule.

[907] Recently Professor Gross and his pupils have emphasized that a complex can also concern crime, and that a criminal can in certain circumstances be unmasked by means of an association test. Laboratory tests designed to verify this assertion are now in progress. Not long ago for the first time, using this method, I succeeded in unmasking a person guilty of a considerable theft.[20]

[908] These results achieved in the field of normality we have transferred to that of psychopathology, and here we have found feeling-toned complexes developed to a degree that amounts to caricature. Here I will first of all name the most common form of mental disorder: *hysteria*.

Here the associations are often so much under the influence of a feeling-toned complex that the other parts of the personality hardly show up at all. The complexes themselves are of the same nature as in normal cases, except that the intensity of the emotional content is far greater than in the normal. As a rule, the times of critical reactions are much longer and the barriers to recollection much stronger than with normal subjects.

[909] From this we can first of all conclude that the sensitivity (i.e., the excitability) of the emotions is greater in hysterical patients than in normal people. An integral part even of hysteria, however, is a complex of images linked with most powerful affect which, for some reason or other, is still reverberating in the patient and which his conscious mind finds unbearable; the *hysterical patient suffers from an affect that he has been unable to conquer*. The recognition of this is of the greatest importance in therapy.

[910] You will now ask what is the relationship of this fact to the enormously complicated *symptomatology of hysteria*.[21] I will explain our view by giving two simple examples.

[911] A hysterical girl suffers from time to time from a minor paralysis of the left arm. She is very worried about it and cannot give any adequate explanation for her symptom. From her associations we learn that there are troubles in the home and, in particular, that she is terrified of her father. By various means, which I unfortunately cannot describe to you now, we induced the patient to make the following confession:

[912] She has a very unhappy relationship with her father, who is a coarse and irritable man. Each time she has had a scene with him the paralysis in her arm comes on. The first time it happened was after a particularly violent argument when her father finally seized her by the arm and forbade her the house.

[913] Thus the symptom of paralysis is closely related to the complex shown in the associations. The complex is the intolerable thing that the patient is trying hard not to think about. She succeeds in freeing herself for days or hours at a time from its constant negative affect, but has

instead acquired a hysterical symptom that she now makes responsible for all her dreary moods.

[914] Another and simpler case concerns a young married woman who suffers temporarily from abasia, i.e., inability to walk. The associations revealed an unhappy marital relationship. The patient, however, did not want to go into the matter and denied absolutely that there was any connection between the abasia and her marriage. She attributed the onset of abasia to a chill. Under hypnosis, however, the matter became quite clear. The attacks of abasia came on each time immediately after brutal treatment by her husband. The first occasion was when she was fetched by this man, whom she did not love, for her wedding. She found she could no longer walk, and from that time onwards abasia had been the symbol of her suffering.

[915] These two simple examples should suffice to make clear to you the connection between the symptoms of hysteria and the feeling-toned complex. In the depths of the mind of each hysterical patient we always find an old wound that still hurts or, in psychological terms, a feeling-toned complex.

[916] Our association experiments have now also been able to demonstrate the same mechanism in cases of the next most prevalent group of mental illnesses, i.e., dementia praecox. In this too we are concerned with a complex buried in the depths of the mind which, so far as we can see, causes many of the characteristic symptoms of this disease, in which admittedly we find ingredients lacking in hysteria.[22]

[917] You may have gathered from these indications on the one hand how fruitful the application of the association experiment is for psychopathology, and on the other how universal is the significance of the feeling-toned complex.

DISTURBANCES OF REPRODUCTION IN THE ASSOCIATION EXPERIMENT[1]

[918] My reproduction method, which I introduced in a short communication in the *Zentralblatt für Nervenheilkunde und Psychiatrie* in 1905,[2] has recently been repeatedly criticized (by A. Gross, Heilbronner, and Isserlin[3]). Because of an undue amount of other work I am, to my regret, only now able to complete my unfinished paper by giving it the support of statistics. In 1905 I maintained the following:

[919] If, after the completion of about one hundred associations, the subject is asked to repeat the original answers to the individual stimulus-words, memory will fail in several places, in such a way that the previous reaction is either not reproduced at all, is given incorrectly, is distorted, or only given after much delay. The analysis of the incorrectly reproduced associations showed that the majority of them were constellated by a "complex." Since most contemporary workers doing research in this field tend to attribute to Freud's psychoanalytical method no heuristic value at all, it is denied to me to take the shortest course and simply corroborate the above statement by means of analyses. To eliminate the subjective aspect of analysis, which is so much feared, I have no choice but to adduce as unobjectionable evidence the objective signs of complex-constellations, complex-characteristics, and their relation to incorrect reproduction. I found that, in associations that were recognizable through complex-characteristics, a complex was responsible for the constellation, i.e., had "interfered" and brought about a disturbance. If these characteristics are really significant, i.e., if the analytical method has led to a correct result that could be verified, then the characteristics in general must stand in close relation to each other, i.e., they must tend to appear together in certain associations. This applies, for instance, to incorrect reproductions and prolonged reaction-times. If this is not the case and the complex-signs are indiscriminately scattered over the whole test, then the analysis has led to a wrong conclusion.

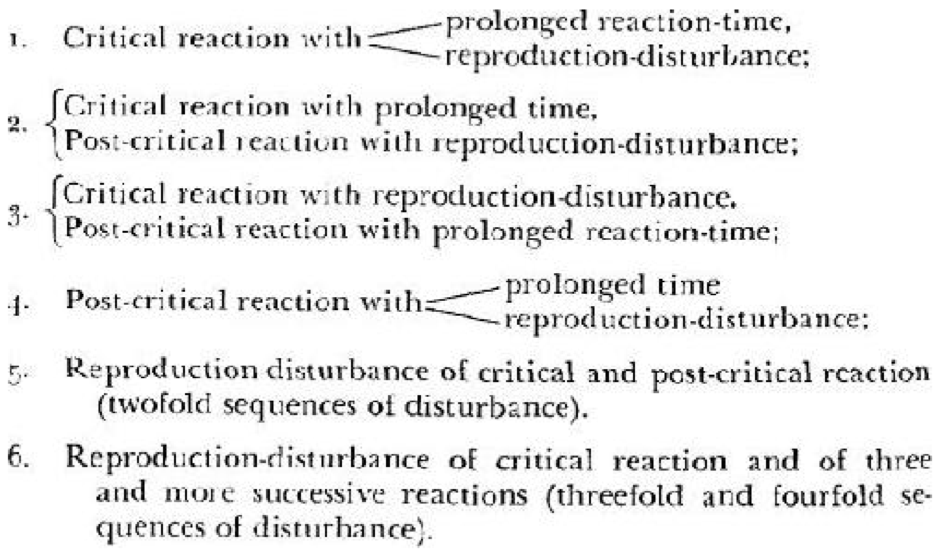
[920] I further mentioned in my previous communication: (1) The incorrectly reproduced associations occasionally have an arithmetical time-mean that exceeds the general arithmetical mean *(one example)*. (2) The incorrect reproductions apparently occur as frequently with the critical as with the post-critical reaction. (3) Occasionally there is a tendency to serial or to isolated disturbances in reproductions. (4) I looked for the theory of the phenomenon in

the general characteristics of the complex. I then stressed one feature in particular, repression (Freud), because precisely this feature seemed to me best to explain the inhibition of the correct reproduction. The main characteristic of the complex is certainly its relative independence, which can manifest itself particularly in two directions: in increased emphasis and stability in consciousness, and in repression, i.e., resistance against reproduction while in the unconscious. Therefore the associations belonging to the complex lack the "disposability" of other less significant psychic material (this, by the way, happens only when the special complex is inhibited and must not come to the point of reproduction). The complex itself, of course, completely, even hypermnestically, controls its material. This reducing of the disturbance of reproduction to a more general psychological characteristic seems to me to explain something. Of course, the hypothesis does not apply to every case, for then one would first have to make sure that all interferences from outside (fortuitous ones) are completely excluded; my hypothesis applies only to the majority of cases, as well as only to the majority of complex-characteristics. (5) The complexes indicated by the association experiment are usually charged with unease, which is why the exceptional condition of the complex during the experiment may well be described as "repression."

[921] It is now my task to demonstrate exactly what my conception is based on, i.e., to prove that the disturbances in reproduction are complex-characteristics, and therefore as a rule appear together with other complex-characteristics. There cannot be a simple method of verification, because we have to consider that the reproduction-disturbance, like all other complex-characteristics, is not a necessary feature of the complex, and also that, like the other complex-characteristics, it is not exclusively tied to the critical reaction but can also occur with the one that follows. The complex-characteristic most frequently met with is the *reaction-time*.

Disturbance in Reproduction and Reaction-time

[922] The most obvious method of comparison would be simply to compare the arithmetical mean of the times of the incorrectly reproduced associations with the arithmetical mean of all the times or of all the remaining times. But this method would only be to some extent reliable if the disturbance in reproduction coincided with the prolonged reaction-times. This, however, is not at all the case; the situation is much more complicated. The following quite varied cases occur:

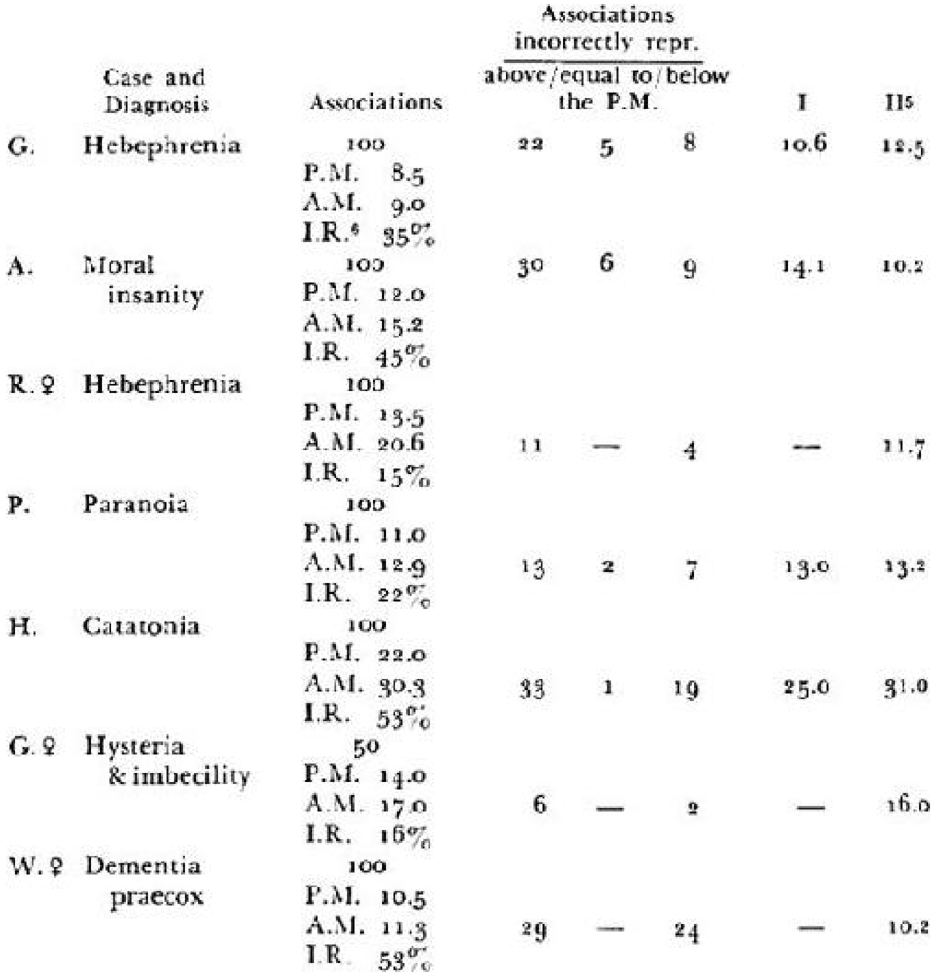


1. Critical reaction with — prolonged reaction-time, — reproduction-disturbance;
2. Critical reaction with prolonged time,
Post-critical reaction with reproduction-disturbance;
3. Critical reaction with reproduction-disturbance,
Post-critical reaction with prolonged reaction-time;
4. Post-critical reaction with — prolonged time — reproduction-disturbance;
5. Reproduction disturbance of critical and post-critical reaction (twofold sequences of disturbance).
6. Reproduction-disturbance of critical reaction and of three and more successive reactions (threefold and fourfold sequences of disturbance).

[923] These complicated relations have to be taken into account by the method. In a previous one of the Diagnostic Association Studies,[4] I used the probable mean to determine the prolonged reaction-times because of the fact that the arithmetical mean is as a rule disproportionally high owing to the undue influence of excessively long times, which obviously cannot be compensated for by excessively short times, since the reaction-time has unlimited variations only in the upper ranges. The probable mean therefore generally gives a much better picture of the average speed of reacting. What exceeds this average may as a rule be considered to be not quite normal. But the probable mean is only applicable for large series of numbers, otherwise it is too inaccurate, because it can be considerably altered by trivial chance-events. For small series of numbers we therefore have to use the arithmetical mean. So I have started with the probable mean of the whole test, first counting how many reaction-times of incorrectly reproduced associations exceed the probable mean, how many equal it, and how many do not reach it. If my previous assumptions are right, then one might expect to find the majority of reproduction-disturbances above the probable mean. Those reproduction-disturbances that fall on or below the probable mean can be due to perseveration and therefore may immediately follow a prolonged reaction-time; one has therefore in these cases to examine the reaction-time immediately preceding the disturbance. Actually the reaction-time immediately following should also be investigated, because the time-increase may not occur until afterwards. This, however, would lead us rather far afield. I have not embarked on this investigation hitherto, because it seemed to me that such cases are not very frequent. Let us first see how far we get with the two just mentioned. I should like to stress that since the methods just mentioned

do not involve the subjective element, we can approach the task of verification with confidence.

[924] The material I have chosen for my inquiry consists of twenty-eight cases, all of which were investigated some time ago and for purposes other than the verification of the present assumption. Not quite a third of the cases were investigated by me, the other two-thirds by various assistants, some of them several years ago. Among the subjects of the experiment only three are mentally sound, the others are neurotics and psychotics of the most varied kinds and of the most varied reaction-types. The material is therefore as heterogeneous as can be, offering the smallest chance of uniformity in the result. I have collected the results in the following table (all the times are given in 1/5 seconds):



Case and Diagnosis		Associations	Associations incorrectly repr. above/equal to/below the P.M.			I	II[5]
G.	Hebephrenia	100 P.M. 8.5 A.M. 9.0 I.R.[6] 35%	22	5	8	10.6	12.5
A.	Moral insanity	100 P.M. 12.0 A.M. 15.2 I.R. 45%	30	6	9	14.1	10.2

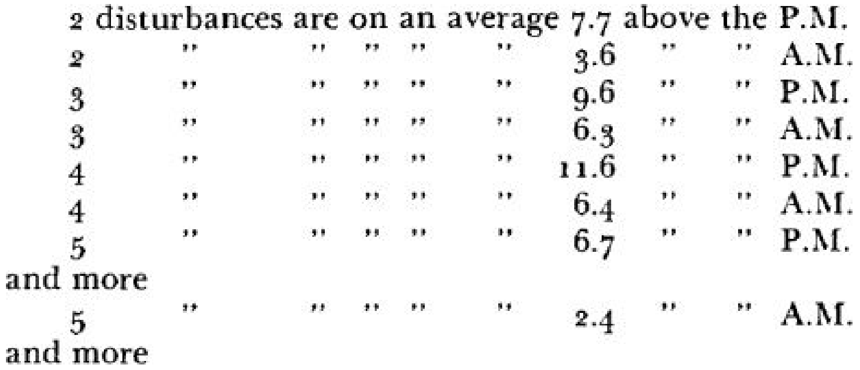
[925] These figures lead to the conclusion that an average of 62.2 per cent of the incorrectly reproduced associations fall above the general probable mean of the reaction-times, 7.5 per cent equal it, and 30.2 per cent lie below. This is as originally expected. An average of 33.0 per cent of the associations is incorrectly reproduced. The time-means of the last two columns have to be considered with the reserve mentioned above. They contain cases of quite different significance. As already stated, only the reaction-time immediately preceding the incorrect reproduction was considered, and this only in those cases in which the incorrect reproduction itself fell below the general time-mean. But it is quite possible that the incorrect reproduction is not the result of perseveration, but that the critical reaction has a short reaction-time, with the longer reaction-time following. In this event the result would be considerably distorted. Therefore we shall be faced with minimum figures. The time taken to give the incorrect reproductions discussed here exceeds, however, the probable mean by an average of 7.8 and the arithmetical mean by 4.1. The values on which this calculation is based vary, however, considerably. The series of numbers in the last column are not so varied and are richer in material, but the same considerations apply to them as to the figures of the last column but one.

Here too we find that the reaction-time preceding these reproduction-disturbances exceeds the respective probable mean by 4.2 and the arithmetical mean by 0.4. Here we are reminded that the arithmetical mean tends to be disproportionally shifted upwards, as is anyhow sufficiently demonstrated by our figures. These figures are not contrary to expectation, but in my opinion confirm our assumption. If one considers how extremely complicated psychic processes are, and how difficult to control, especially in the field of associations, one is actually amazed at the relative regularity of the results, which cannot even be compromised by a schema that does not claim to be complete.

Series of Disturbance and Reaction-time

[926] In my material, 63.9 per cent of all the incorrect reproductions are arranged in series. This fact shows that there is every reason to postulate a relationship between incorrect reproduction and complex, since the complex with its perseveration is a series-forming factor *par excellence* in the association experiment as well as in ordinary psychological life (which, according to the opinion of certain people, must not be related to psychology). If this conclusion by analogy is right, then the series of disturbances must show the same complex-characteristics as the complex-sequences; hence, first of all prolonged reaction-times. In order not to amass unnecessary tables I omit giving figures for each subject. That there is enough material to calculate averages is evident from the above-mentioned percentage figure. The number of the incorrect reproductions underlying this calculation amounts to a little more than six hundred. We calculate the arithmetical mean for all the incorrectly reproduced associations following one another immediately and compare the mean with the probable mean and arithmetical mean for each subject. Sequences of



2	disturbances	are	on	an	average	7.7	above	the	P.M.
2	"	"	"	"	"	3.6	"	"	A.M.
3	"	"	"	"	"	9.6	"	"	P.M.
3	"	"	"	"	"	6.3	"	"	A.M.
4	"	"	"	"	"	11.6	"	"	P.M.
4	"	"	"	"	"	6.4	"	"	A.M.
5 and more	"	"	"	"	"	6.7	"	"	P.M.
5 and more	"	"	"	"	"	2.4	"	"	A.M.

[927] We see an increase of the time-values up to the series of four disturbances, whereas for the series of five and more they are again lower. This result does

not fit badly with the analytic consideration. Not infrequently we can see a strong complex perseverating through three and four disturbances, sometimes with uneven decrease of the reaction-times. The stronger is the complex aroused, the stronger, *cum grano salis*, will be the disturbances produced by it. In longer series, however, (which in any case are much less frequent), other factors that interfere with the experiment often appear.

[928] We can summarize by saying: *In the main the disturbance in reproduction is correlated with a prolonged reaction-time; where it is not correlated with this, the preceding reaction-time tends to be prolonged in the majority of cases*. (The question of the reaction-time following is left open, because it is of secondary importance.)

[929] One can apply another, perhaps even more instructive, method to demonstrate the higher time-values of the disturbance-sequences. I have taken twenty-four cases with well-developed sequences from my material and arranged them in two categories as follows: First, those series that begin with a reaction-time longer than that of the immediately preceding associations, thus:

Association	Disturbances				Assoc corr repr. of s
correctly repr.	I	II	III	IV	
9	10	8	6	6	
10	82	15	—	—	1
6	92	15	8	—	
12	35	16	16	—	1

etc.

[930] In this way I have arranged one hundred and nineteen series of this category, added the individual columns, and divided by the numbers of figures in each column.

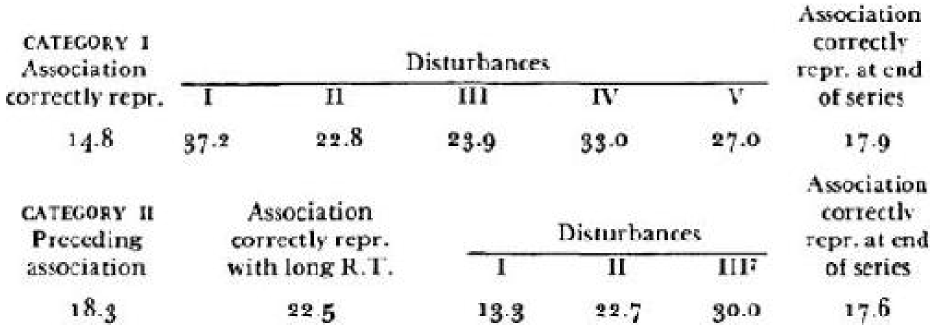
[931] The second category concerns those series in which the disturbance begins with a reaction that is shorter than that of the immediately preceding correctly reproduced association. For the purpose of comparison I have also taken the reaction-time of the association preceding the one before the disturbance, no matter whether it has been correctly or incorrectly reproduced. Those complicated by “mistakes” were excluded from the calculation, although such sequences would have made my results even more impressive.

[932] This category is therefore composed as follows:

Preceding association	Association correctly repr. with long R.T.	Disturbances I	 II	 III	Assoc corr repr. of s
14	17	8	21	—	1
12	15	13	55	12	1
8	40	12	20	—	9

etc.

[933] This category consists of 56 sequences. A few sequences in which the correctly reproduced associations and the first disturbance of the series had the same reaction-time were equally distributed among the two categories. The results are as follows (given in arithmetical means and in 1/5 seconds):



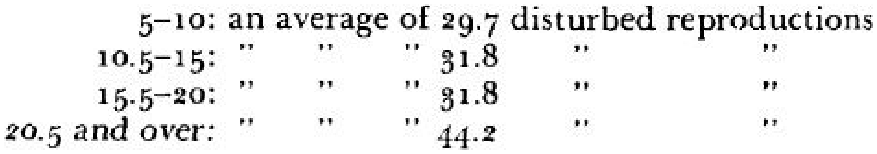
CATEGORY I Association correctly repr.	Disturbances I	 II	 III	 IV	 V	Association correctly repr. at end of series
14.8	37.2	22.8	23.9	33.0	27.0	17.9

CATEGORY II Preceding association	Association correctly repr. with long R.T.	Disturbances I	 II	 III[7]	Association correctly repr. at end of series
18.3	22.5	13.3	22.7	30.0	17.6

The average arithmetical time-mean of the 24 cases used here is 19.8. We see therefore that all our times, with *one* exception, lie considerably above this mean. The exception is found in those reproductions (Category II) which immediately follow a prolonged reaction-time.

Reproduction-disturbance and Probable Time-mean

[934] If, as appears proved by the preceding investigation, the reproduction-disturbance occurs mainly in conjunction with prolonged times, one may venture the assumption that the number of disturbances with longer individual time-means generally increases. This seems, at least according to my (limited) material, to be actually the case. To a probable mean of



5–10: an average of 29.7 disturbed reproductions
10.5–15: " " " 31.8 " "
15.5–20: " " " 31.8 " "
20.5 and over: " " " 44.2 " "

To clarify this particular question, however, much more material is necessary.

Reproduction-disturbance and Complex-characteristics, excluding Prolonged Reaction-times

[935] Besides prolonged reaction-times, I found the following to be complex-characteristics: reaction by two or more words if subject usually responds with one word, repetition of the stimulus-word, misunderstanding of the stimulus-word, mistakes, slips of the tongue, translation into a foreign language, reaction with some other unusual foreign word, insertion of “yes” or other exclamations before or after the reaction, any unusual contents of the reaction, perseveration as to content or form, etc. The evaluation of the originality of the content and opinion on the perseveration of content and form are subject to personal influences. Therefore I omit these two criteria from my investigation. I have only used the quite obvious perseveration of a reaction-word which reappears identically in the following reaction. I have selected from my material nineteen cases which are characterized by the fact that they mainly responded with only one word. I have counted how many of the above-mentioned complex-characteristics occur in the whole experiment and how many of these are incorrectly reproduced associations.

[936] The following table contains the results of this investigation in individual figures:

	Complex-characteristics for Associations Reproduced	
	correctly	incorrectly
1.	0.08	0.16
2.	0.11	0.31
3.	0.03	0.27
4.	0.03	0.11
5.	0.15	0.20
6.	0.11	0.28
7.	0.37	0.40
8.	0.08	0.26
9.	0.06	0.16
10.	0.12	0.42

11.	0.27	0.39
12.	0.03	0.18
13.	0.06	0.15
14.	0.01	0.02
15.	0.06	0.33
16.	0.23	0.29
17.	0.04	0.15
18.	0.31	0.54
19.	0.18	0.29

[937] If one considers that not all complex-reactions are necessarily reproduced incorrectly, and that the incorrectly reproduced associations comprise only one third of all the associations (in my material), then the result conveyed to us by the above table is still rather remarkable: we see that, in each case without exception, more complex-characteristics are produced with those associations that are going to be reproduced incorrectly later on. As a rule, they are recognizable beforehand. The incorrectly reproduced associations show on an average a little more than twice as many complex signs as those correctly reproduced.

Summary

[938] In my very heterogeneous material there is undoubtedly a relation between incorrect reproduction and prolonged reaction-time, and it shows itself in such a way that disturbances of reproduction chiefly occur with prolonged reaction-times but also partly following these. Furthermore, the association that is afterwards incorrectly reproduced has on average twice as many complex-signs as the correctly reproduced one (except for the over-long reaction-time, contents subjectively evaluated, and the correlated perseveration). From this it follows that the complex-characteristics tend to be grouped around certain associations. Without analyzing these one cannot see where the relationships between these greatly varying complex-characteristics originate.

THE ASSOCIATION METHOD[1]

[939] *Ladies and Gentlemen:* When you honoured me with an invitation to lecture at Clark University, you expressed a wish that I should speak about my methods of work and especially about the psychology of childhood. I hope to accomplish this task in the following manner:

[940] In my first lecture I shall tell you about the general points of view that enabled me to conceive my association method; in the second I shall discuss the significance of the family constellation; and in the third I shall go more fully into the psychology of the child.

[941] I could easily confine myself exclusively to an exposition of my theoretical views, but I believe it will be better to illustrate my lectures with as many practical examples as possible. We shall therefore concern ourselves first with the association test, which has been of great value to me from both a practical and a theoretical point of view. The historical development of the association method and its use in psychology are both so well known to you that there is no need to enlarge upon them. In my practice I proceed by using the following set of words:[2]

1. head
2. green
3. water
4. to sing
5. death
6. long
7. ship
8. to pay
9. window
10. friendly

11. table
12. to ask
13. cold
14. stem
15. to dance
16. village
17. lake
18. sick
19. pride
20. to cook
21. ink
22. angry
23. needle
24. to swim
25. journey
26. blue
27. lamp
28. to sin
29. bread
30. rich
31. tree
32. to prick
33. pity
34. yellow
35. mountain

36. to die
37. salt
38. new
39. custom
40. to pray
41. money
42. stupid
43. exercise-book
44. to despise
45. finger
46. dear
47. bird
48. to fall
49. book
50. unjust
51. frog
52. to part
53. hunger
54. white
55. child
56. to pay attention
57. pencil
58. sad
59. plum
60. to marry

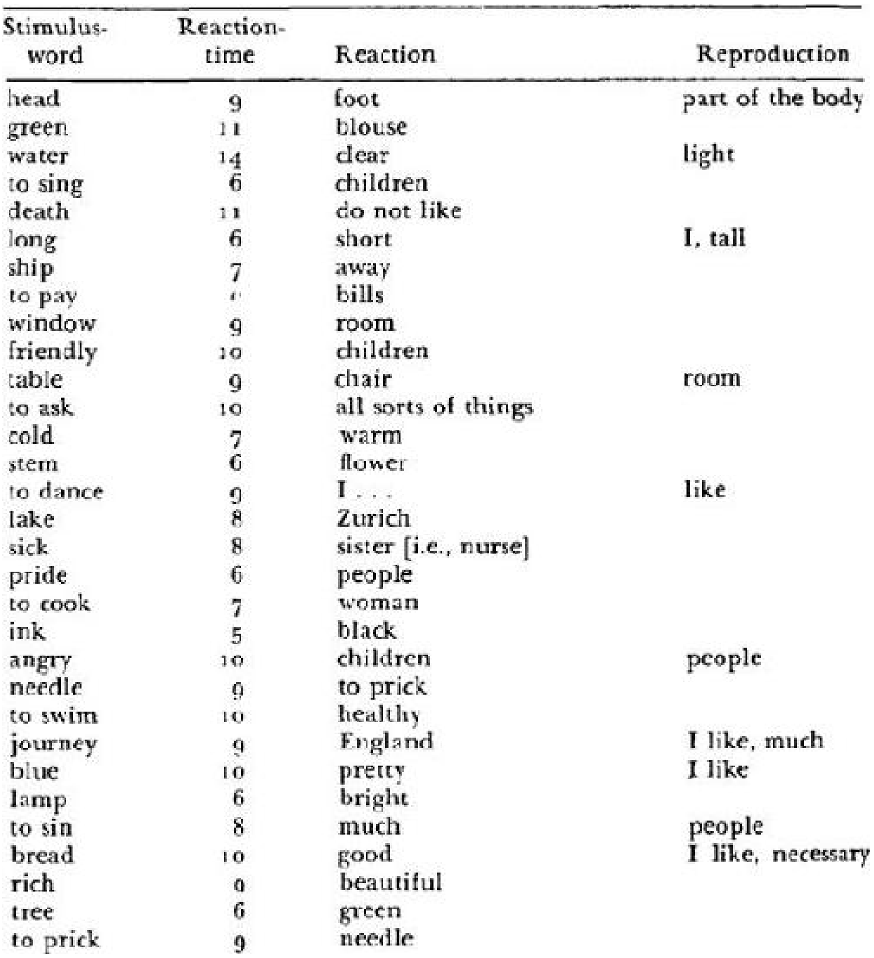
61. house
62. darling
63. glass
64. to quarrel
65. fur
66. big
67. carrot
68. to paint
69. part
70. old
71. flower
72. to beat
73. box
74. wild
75. family
76. to wash
77. cow
78. friend
79. happiness
80. lie
81. deportment
82. narrow
83. brother
84. to fear
85. stork

86. false
87. anxiety
88. to kiss
89. bride
90. pure
91. door
92. to choose
93. hay
94. contented
95. ridicule
96. to sleep
97. month
98. nice
99. woman
100. to abuse

[942] This set of words has grown into its present form as a result of many years of experience. The words are chosen and to some extent arranged so as to touch upon almost all the complexes that commonly occur in practice. As the foregoing list shows, there is a regular mixture of the different grammatical features. For this there are definite reasons.

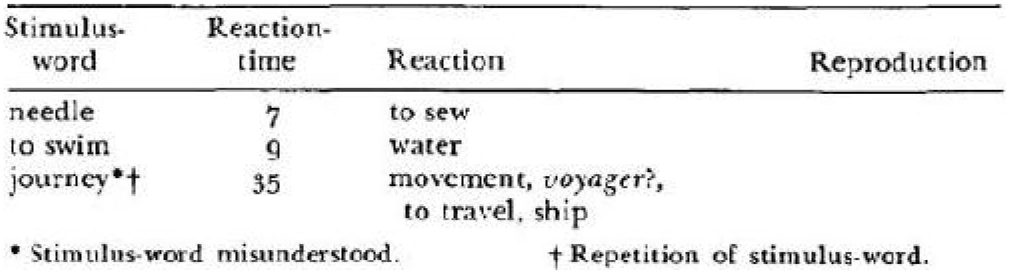
[943] Before the experiment begins the subject of the test is given the following instruction: "Answer as quickly as possible with the first word that occurs to you." This instruction is so simple that it can easily be followed. The task itself, moreover, appears extremely easy, so that anyone might be expected to accomplish it with the greatest ease and rapidity. But, contrary to expectation, people behave quite differently.

I. Example of a Normal Reaction-type



Stimulus-word	Reaction-time	Reaction	Reproduction
head	9	foot	part of the body
green	11	blouse	
water	14	clear	light
to sing	6	children	
death	11	do not like	
long	6	short	I, tall
ship	7	away	
to pay	[illegible]	bills	
window	9	room	
friendly	10	children	
table	9	chair	room
to ask	10	all sorts of things	
cold	7	warm	
stem	6	flower	
to dance	9	I . . .	like
lake	8	Zurich	
sick	8	sister [i.e., nurse]	
pride	6	people	
to cook	7	woman	
ink	5	black	
angry	10	children	people
needle	9	to prick	
to swim	10	healthy	
journey	9	England	I like, much
blue	10	pretty	I like
lamp	6	bright	
to sin	8	much	people
bread	10	good	I like, necessary
rich	0	beautiful	
tree	6	green	
to prick	9	needle	

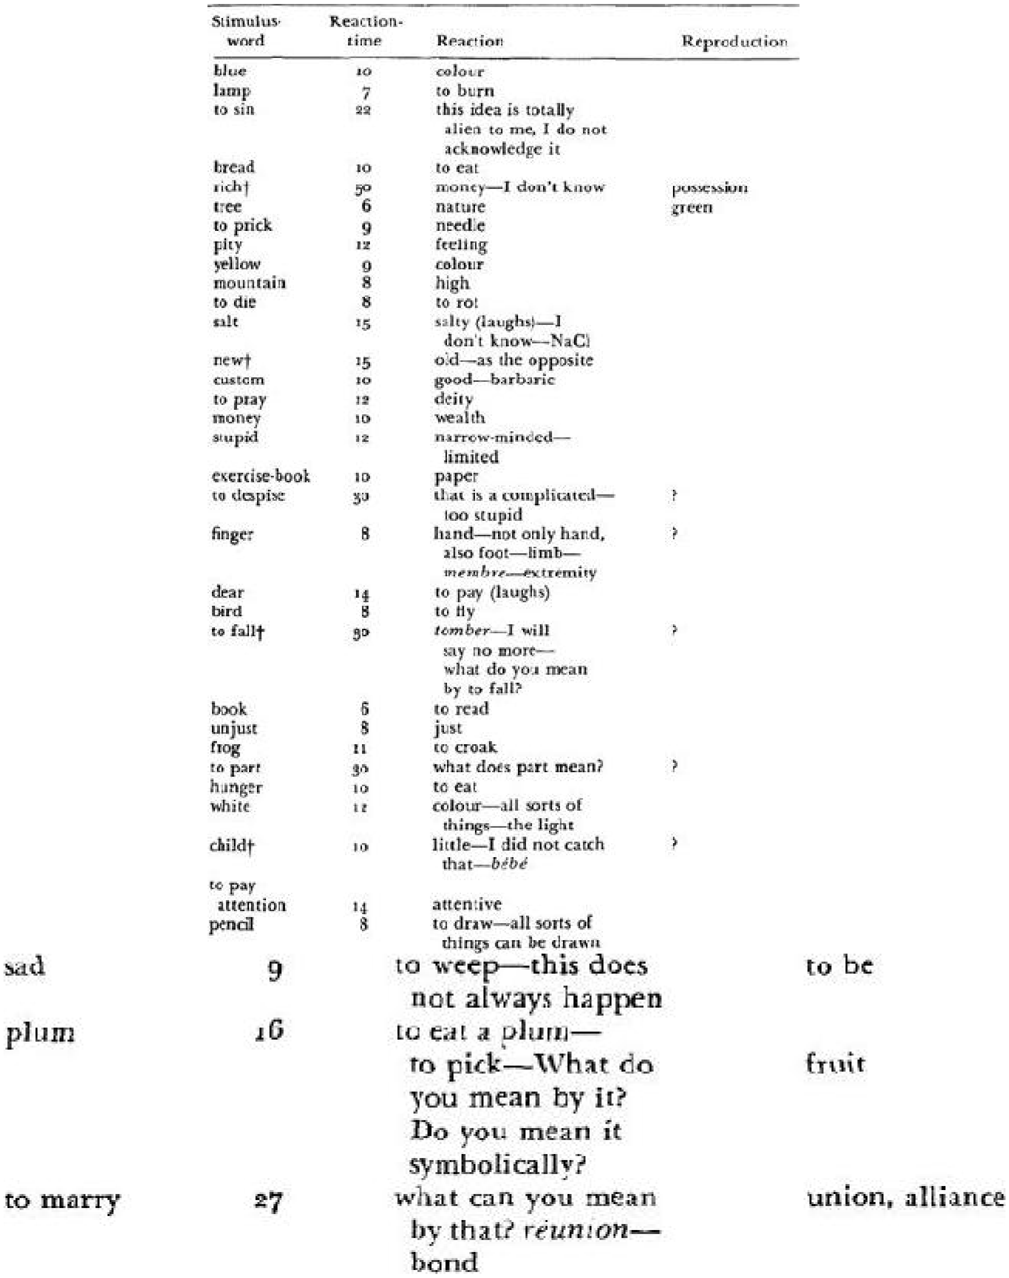
II. Example of a Hysterical Reaction-type



Stimulus-word	Reaction-time	Reaction	Reproduction
needle	7	to sew	
to swim	9	water	
journey*†	35	movement, *voyager*?, to travel, ship	

* Stimulus-word misunderstood. † Repetition of stimulus-word.

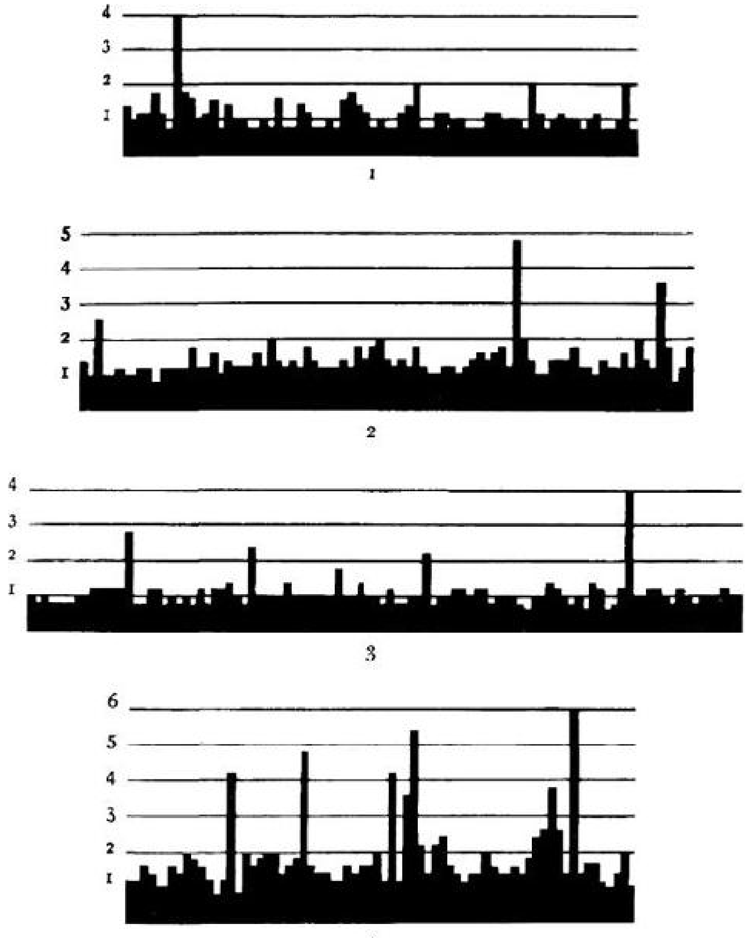
The Association Method



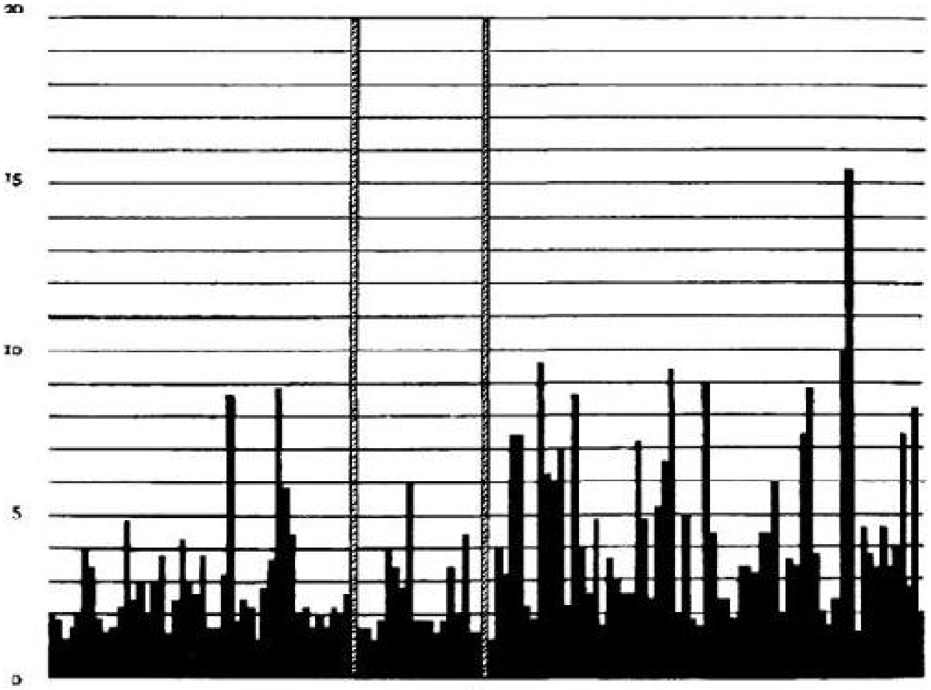
Stimulus-word	Reaction-time	Reaction	Reproduction
blue	10	colour	
lamp	7	to burn	
to sin	22	this idea is totally alien to me, I do not acknowledge it	
bread	10	to eat	
rich†	50	money—I don't know	possession
tree	6	nature	green
to prick	9	needle	
pity	12	feeling	
yellow	9	colour	
mountain	8	high	
to die	8	to rot	
salt	15	salty (laughs)—I don't know—NaCl	
new†	15	old—as the opposite	
custom	10	good—barbaric	
to pray	12	deity	
money	10	wealth	
stupid	12	narrow-minded—limited	
exercise-book	10	paper	
to despise	30	that is a complicated—too stupid	?
finger	8	hand—not only hand, also foot—limb—*membre*—extremity	?
dear	14	to pay (laughs)	
bird	8	to fly	
to fall†	30	*tomber*—I will say no more—what do you mean by to fall?	?
book	6	to read	
unjust	8	just	
frog	11	to croak	
to part	30	what does part mean?	?
hunger	10	to eat	
white	12	colour—all sorts of things—the light	
child†	10	little—I did not catch that—*bébé*	?
to pay attention	14	attentive	
pencil	8	to draw—all sorts of things can be drawn	
sad	9	to weep—this does not always happen	to be
plum	16	to eat a plum—to pick—What do you mean by it? Do you mean it symbolically?	fruit
to marry	27	what can you mean by that? *réunion*—bond	union, alliance

[944] The first thing that strikes us is the fact that many subjects show a marked prolongation of the reaction-time. This would seem to suggest intellectual difficulties—wrongly, however, for we are often dealing with very intelligent people with a good command of language. The factor responsible for this is connected with their feelings. In order to understand this, we must bear in mind that the association experiments investigate not just *one* component of the mind, since no psychological experiment can possibly be concerned with one isolated psychic function; no psychic occurrence is a thing in and by itself but rather the resultant of

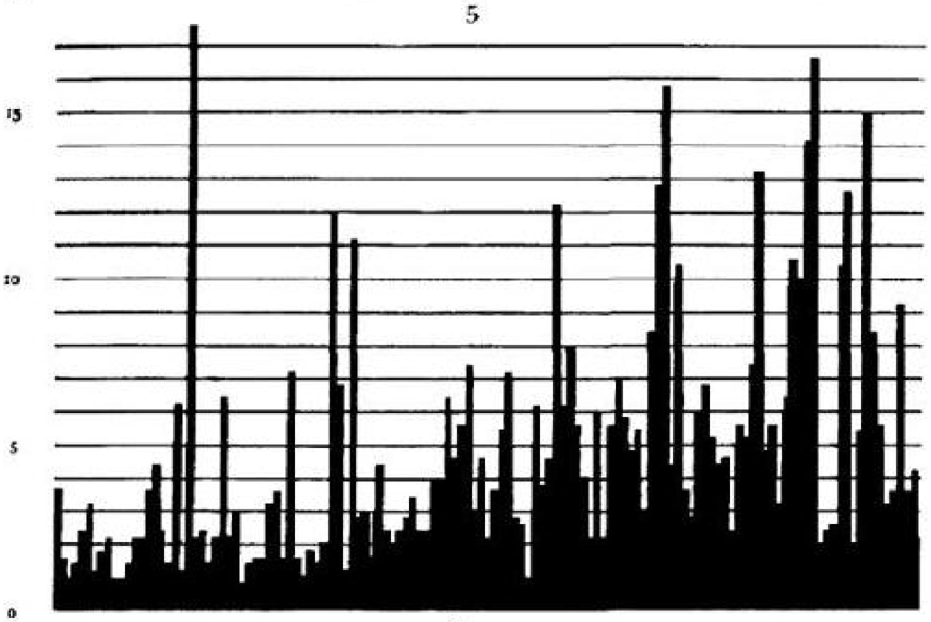
the entire psychological past. The association experiment, too, is not merely a method for the reproduction of separate word-pairs but a kind of pastime, a conversation between experimenter and subject. In a certain sense it is even more than this. Words are really a kind of shorthand version of actions, situations, and things. When I present the subject with a stimulus-word meaning an action, it is as if I presented him with the action itself and asked him, “How do you feel about it? What’s your opinion of it? What would you do in such a situation?” If I were a magician, I should cause the situation corresponding to the stimulus-word to appear in reality and, placing the subject in the centre, I should then study his reactions. Undoubtedly the effect of my stimulus-words would be much more perfect. But as we are not magicians, we must content ourselves with the linguistic surrogates for reality; at the same time we must not forget that the stimulus-word will almost without exception conjure up its corresponding situation. All depends on how the subject reacts to this situation. The word *bride* or *bridegroom* will not evoke a simple reaction in a young girl; but the emerging strong feeling tones will markedly influence the reaction and even more so if the experimenter is a man. So the subject is often unable to react quickly and smoothly to all stimulus-words. There are certain stimulus-words that denote actions, situations, or things about which the subject is also in reality unable to think quickly and with certainty, and this fact is demonstrated in the association experiments. The example I have just given shows an abundance of long reaction-times and other disturbances. In this case the reaction to the stimulus-words is obviously in some way inhibited—that is, the adaptation to the stimulus-words is disturbed. Stimulus-words are, however, nothing but part of the reality that impinges upon us; in a certain sense someone who shows such disturbances when confronted with stimulus-words is on the whole *inadequately adapted to reality*. Any disease springs from impaired adaptation; thus in our special case we are dealing with something morbid in the psyche, with something either temporarily or permanently pathological. That is, we are dealing with a psychoneurosis, with a functional disturbance of the mind.



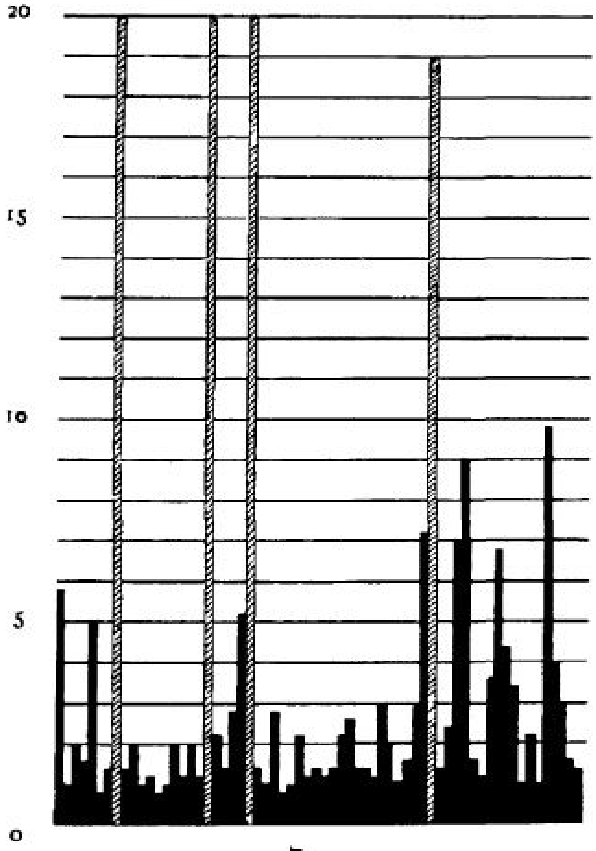
FIGS. 1–4. These graphs illustrate the reaction-times in an association experiment on four normal subjects. The height of each column indicates the length of the reaction-time



5



6



7

FIGS. 5–7. These graphs show the profiles of the reaction-times in hysterical individuals. The lightly cross-hatched columns indicate places where the subject was unable to react (referred to as failures)

[945] This rule is, as we shall see later, not without its exceptions.

[946] Let us now continue the discussion of the prolonged reaction-times. It often happens that the subject actually finds *no* answer to the stimulus-word. He fails to give any reaction and so for the moment abandons his agreement to follow the original instructions, showing himself incapable of adapting to the experiment. If this phenomenon occurs often in an experiment, it indicates that adaptation is seriously disturbed. I should like to remark that the reasons the subject gives for the refusal are utterly immaterial. Some find that too many ideas suddenly occur to them; others, that too few ideas enter their minds. In most cases, however, the difficulties experienced at first are so much of a deterrent that the subjects actually give up the reaction altogether. Example III shows a case of hysteria with many failures of reaction.

[947] In example II we find a characteristic phenomenon: the subject is not content with the terms of the instruction; that is, he is not satisfied with *one* word but reacts with many. He apparently does more and better than the instruction requires, but in so doing he does not fulfil the terms of the

instruction. Thus he reacts: *custom / good—barbaric; stupid / narrow-minded—limited;* all sorts of things.

III

Stimulus-word	Reaction-time	Reaction	Reproduction
to sing	9	beautiful	
death	15	terrifying	?
long*†	40	the time, the journey	?
ship†	—	—

* Stimulus-word misunderstood. † Repetition of stimulus-word.

[948] These examples show, first, that many more ideas are added to the reaction-word. The subject is unable to suppress these further ideas. In this way he also pursues a certain tendency that is more clearly expressed in the following reaction: *new / old—as the opposite*. The addition of *as the opposite* hints that the subject needs to add something explanatory or supplementary. This tendency is also shown in the following reaction: *finger / hand—not only hand, also foot—a limb—membre—extremity*.

[949] Here we have a whole series of additions. It seems as if the reaction were not sufficient for the subject, as if something else must always be added, as if what has already been said were incorrect or in some way incomplete. This feeling is what Janet calls the “sentiment d’incomplétude”; but this, however, does not explain anything. I am enlarging on this phenomenon because it is very common in neurotic individuals. It is not merely a trivial and incidental

phenomenon in an experiment without significance, but rather an essential and universal phenomenon that plays a large part in the psychic life of neurotics.

[950] By his desire to supplement, the subject betrays a tendency to give the experimenter more than he wants; he actually labours in his attempts to find further ideas so as eventually to find something entirely satisfactory. If we translate this elementary observation into the psychology of everyday life, it means that the subject has a tendency always to give to others more feeling than is demanded or expected. According to Freud, this is a sign of a reinforced object-libido, that is, it is a compensation for an inner discontent and lack of feeling. This elementary observation therefore points to one of the chief characteristics of hysterical patients, namely, the tendency to let themselves be carried away by everything, to fix their passion onto everything, and always to promise too much and hence keep only a few of their promises. Patients with this symptom are, in my experience, always rather disagreeable; at first they are enthusiastically enamoured of the physician, for a time going so far as blindly to accept everything he says; but they soon fall into an equally blind resistance to him, thus rendering any psychological influence absolutely impossible.

[951] In this phenomenon we see the expression of a tendency to give more than the instruction asks for or expects. This tendency also betrays itself in other failures to follow the instruction:

to quarrel	angry—all sorts of things—I always quarrel at home
to marry	what can you mean by that? *reunion*—bond
plum	to eat a plum—to pick—what do you mean by it? do you mean it symbolically?
to sin	this idea is totally alien to me, I do not acknowledge it

[952] These reactions show that the subject is not playing his part in the experiment. For the instruction is that he should answer only with the first word that occurs to him. But here it appears that the stimulus-words have an excessively strong effect, that they are taken absolutely *personally,* as if they were direct questions. The subject entirely forgets that he is faced with mere words presented in print. He looks for a personal meaning in them, tries to guess the meaning and defend himself against it, altogether forgetting the original instruction.

[953] This elementary observation illustrates another common peculiarity of hysterical patients, namely, that of taking everything personally, of never being able to be objective and of allowing themselves to be carried away by momentary impressions; again the characteristic of the reinforced object-libido.

[954] Yet another sign of difficulty in adaptation is the frequent *repetition of the stimulus-word*. The subjects repeat the stimulus-word as if they had not heard it distinctly or understood it. They repeat it just as we repeat an expected and difficult question so as to grasp it better and be able to answer it. This same tendency is shown in the experiment. The stimulus-words are repeated because they influence hysterical individuals as difficult personal questions do. In principle it is the same phenomenon as the additions to the reaction.

[955] In many experiments we observe that the same reaction often occurs in response to the most varied stimulus-words. These words seem to tend especially to be repeated, and it is very interesting to find out what these words really mean to the subject. I have, for instance, observed a case in which the patient repeatedly reacted with the word *short* a great many times, often in places where it made no sense. The subject could not give the precise reason for repeating the word. From experience I knew that such predicatory words always refer either to the subject himself or to the person nearest to him. I assumed that he was referring to himself as “short” and in this way expressed something very painful to him. The subject was of very small stature. He was the youngest of four brothers; the others, in contrast to himself, were very tall. He was always the *child* in the family; he was nicknamed “Short” and was treated by all as the “little one.” This resulted in a total loss of self-confidence. Although he was intelligent, and in spite of long study, he could not make up his mind to sit for an examination; he finally became impotent, and sank into a psychosis in which, whenever he was alone, he took great pleasure in walking about his room on his toes in order to appear taller. The word *short*, therefore, stood to him for a great many painful experiences. This is usually the case with perseverated words; they always express something very important in the individual psychology of the subject.

[956] The characteristics so far described do not occur at random in the experiment, but are found at very definite points, namely, where the stimulus-words touch upon emotionally charged complexes. This fact is the foundation of what is called the *diagnosis of evidence*, i.e., the art of detecting, by means of an association experiment, the real culprit among a number of people suspected

of a crime. That this is possible I will demonstrate by a brief account of an actual case.[3]

[957] On February 6, 1908, our matron informed me that one of the nurses had complained to her that on the previous afternoon she had been robbed. Here are the facts: The nurse had her money, which amounted to seventy francs, in a purse that she kept in her clothes-cupboard. The cupboard had two compartments; one belonged to the nurse who had been robbed and the other to the charge nurse. These two nurses slept in the same room (with the cupboard in it), together with a third nurse, who was an intimate friend of the charge nurse. The room was in a section of the hospital where normally six nurses were on duty and these could go into the room and use it if they wanted to. In view of this situation it was not surprising that the matron shrugged her shoulders when I asked her whom she suspected in the first place.

[958] From further investigation it appeared that on the day of the theft the friend of the charge nurse had stayed in bed the whole morning because she did not feel very well. According to the evidence of the first nurse, the theft must have taken place during the afternoon. Among the other four nurses on whom suspicion might fall, there was one whose regular duty it was to clean the room, whereas the other three had no official business there, and it did not appear that any of them had been in the room, for whatever reason.

[959] It was therefore very natural that the last three nurses were for the time being regarded as less suspect; I therefore first subjected the first three to the experiment.

[960] From the particulars of the case I also knew that the cupboard was locked but that the key was near by and could easily be found; that on opening the cupboard the first thing visible was a fur stole, and that the purse was hidden in an inconspicuous place between the linen. The pocketbook was made of dark red leather and contained the following: one fifty-franc note, one twenty-franc piece, a few centimes, a little silver watch-chain, a seal for marking the crockery in the hospital, and a receipt from the Dosenbach shoe-shop in Zurich.

[961] Apart from the nurse who had been robbed, and the culprit, only the charge nurse knew the exact particulars of the robbery, since the nurse who had been robbed thought at first that she had lost the money and asked the charge nurse to help her look for it. So the charge nurse was in a position to know the minutest detail of the case; this made the experiment particularly difficult because she was one of the most likely suspects. The conditions of the experiment were

more favourable as far as the other nurses were concerned, since they did not know any of the particulars of the evidence and some of them did not even know that a robbery had been committed. As critical stimulus-words I chose the name of the nurse who had been robbed and also the following: *cupboard, door, open, key, yesterday, banknote, gold, 70, 50, 20, money, watch, purse, chain, silver, to conceal, fur, dark red, leather, centimes, seal, receipt, Dosenbach*. Besides these words which referred to the evidence proper, I also chose the following, which have a special affective value: *theft, to take, to rob, suspect, to accuse, court, police, to lie, to fear, to discover, to arrest, innocent*.

[962] Against words of this last type it has been objected that they carry a strong emotional charge even for the innocent and that there is therefore no value in confronting people with them. We still, however, have to consider whether in an innocent person the affective charge has the same effect on the associations as it has in a guilty one, a question that cannot be answered *ex cathedra* but only through experience. Until proof to the contrary is forthcoming I maintain that words of this class can also produce useful results.

[963] I next distributed these critical stimulus-words among double the number of ordinary stimulus-words, so that for each critical word there were two ordinary ones. It is an advantage for the critical words to be followed by ordinary ones so that the influence of the former may stand out all the more clearly. One can, however, also let one critical word follow another when one wants to show up especially the importance of the second. I therefore put together *dark red* and *leather,* as well as *chain* and *silver*.

[964] After these preparations I started the experiment on the three nurses. Since it is very difficult to present investigations of this kind in a foreign language I cannot give a full report on them here, but I shall content myself with giving an account of the general results and adding some examples. First, I subjected the friend of the charge nurse to the experiment; considering the circumstances, she seemed to be only slightly upset. Then I examined the charge nurse herself, who seemed to be possessed by a considerable agitation and who immediately after the experiment still had a pulse rate of 122 per minute. Lastly I dealt with the nurse who was responsible for cleaning the room where the theft had taken place. She was the calmest of them all; she was only slightly embarrassed and only in the course of the experiment did she realize that she was a possible suspect; towards the end of the experiment this manifestly disturbed her.

[965] The outcome of the examination spoke very much against the charge nurse who, it seemed to me, showed a suspicious reserve—I would almost say

impudence. With the precise idea of finding her guilty, I applied myself to the calculation of the results.

[966] One can use all sorts of methods of computation, but they are not all equally good and equally exact. (One must always base one's judgment on calculation, because appearances are most deceptive!) The method most to be recommended is that of the probable mean of the reaction-times. It gives one a glimpse of the difficulties that the subject of the experiment has had to overcome in reacting.

[967] The technique of this calculation is very simple: the probable mean is the number in the middle of the series of reaction-times. The reaction-times[4] are, for instance, arranged in the following manner: 5, 5, 5, 7, 7, 7, 7, *8*, 8, 9, 9, 9, 12, 13, 14; the middle number (8) is the probable mean of this series. I indicate the friend of the charge nurse by the letter A, the charge nurse by the letter B, and the third nurse by the letter C.

[968] The probable means of the reaction-times are A, 10.0; B, 12.0; C, 13.5. From this result one cannot draw any conclusion.

[969] The means of the reaction-times for the reactions without special significance, for the critical reactions, and for those immediately following ("post-critical"), calculated separately, are, however, of greater interest.

Probable Means of the Reaction-times

	A	*B*	*C*
Neutral reactions	10.0	11.0	12.0
Critical reactions	16.0	13.0	15.0
Post-critical reactions	10.0	11.0	13.0

[970] Here is what results from this table: although A has the lowest mean of the reaction-time for neutral reactions, she has, in contrast to the other two subjects of the experiment, the longest reaction-time for the critical reactions.

[971] The difference between the reaction-times for, let us say, neutral reactions and critical reactions is 6 for A, 2 for B, 3 for C; thus, about twice as high for A as for either of the others.

[972] By calculations similar to those we have made for the reaction-times, we can work out how many complex-characteristics there are on an average for ordinary, critical, and other reactions.

Mean of the Complex-characteristics for All Reactions

	A	B	C

Neutral reactions	0.6	0.9	0.8
Critical reactions	1.3	0.9	1.2
Post-critical reactions	0.6	1.0	0.8

[973] The difference between the neutral and the critical reactions is 0.7 for A, o for B, and 0.4 for C: A therefore leads.

[974] The next question concerns incorrect reproductions. The results of the computation are 34 per cent for A, 28 per cent for B, and 30 per cent for C. One can see that, in this connection also, A reaches the maximum value, and in this I seem to see a characteristic of A's guilt-complex. I cannot, however, set out here the reasons why I maintain that there is a connection between errors of memory and emotional complexes, since this would lead me beyond the scope of the present investigation. I therefore refer the reader to my paper "On Disturbances in Reproduction in the Association Experiment" [supra].

[975] It often happens in the experiment that an association with a strong affective charge leaves behind it a perseveration, in the sense that not only the critical association itself but also two or three of the subsequent associations are incorrectly reproduced; it is therefore interesting to see what one finds if one arranges these associations in a series. The results of the computation are 64.7 per cent for A, 55.5 per cent for B, and 30.0 per cent for C.

[976] Here again we find that A has the largest percentage. This may be partly due to the fact that A also has the largest number of incorrect reproductions: given the small number of reactions, it is obvious that the number of incorrect reproductions in a group increases in proportion to the total number of reactions. Even though this is probable, it can only happen to the same extent in experiments such as ours, in which B and C do not have a much smaller number of incorrect reproductions than A. It is significant that C, with her comparative lack of emotion during the experiment, has the minimum of incorrect reproductions in a series.

[977] Since incorrect reproductions are also complex-characteristics, we need to find out how the incorrect reproductions of neutral reactions, critical reactions, and so on are distributed.

Incorrect Reproductions

	A	B	C
Neutral reactions	10.0	12.0	11.0
Critical reactions	19.0	9.0	12.0

Post-critical reactions	5.0	7.0	7.0

[978] There is no need to add anything to emphasize the differences between neutral reactions and critical reactions in the different subjects: A leads in this respect also.

[979] In this case, of course, the larger the number of critical reactions, the greater is the probability of a large number of incorrect reproductions. Supposing that the incorrect reproductions are distributed evenly and at random among all the reactions, then there will be a greater number for A (compared with B and C) as a reaction to critical words, since A has the largest number of incorrect reproductions. Admitting such a uniform distribution of incorrect reproductions, we can easily calculate how many of them belong to each single class of reaction.

Incorrect Reproductions

	TO BE EXPECTED			ACTUALLY OCCURRING		
	Neutral Reactions	Critical Reactions	Post-crit. Reactions	Neutral Reactions	Critical Reactions	Post- React
A	11.2	*12.5*	10.2	10.0	*19.0*	5.0
B	9.2	*10.3*	8.4	12.0	*9.0*	7.0
C	9.9	*11.1*	9.0	11.0	*12.0*	7.0

[980] From this table it appears that the disturbances of reproduction of the critical reactions of A greatly exceed the expectation, whereas for C the figures are only 0.9 above expectation and for B the actual number is smaller.

[981] All these data are pointers to show that in subject A the critical stimulus-words have acted with the greatest intensity so that the maximum suspicion falls on A. One could venture to declare this subject as the presumptive culprit: and on the same evening she made a full confession of the theft and thus confirmed the success of the experiment.

[982] I maintain that a result so obtained is scientifically interesting and worthy of discussion. In experimental psychology there are many much less useful things than those with which we are dealing in this paper. Completely disregarding the theoretical interest, we have to take into account the not inconsiderable practical result: we have unmasked the culprit without the usual formalities, merely by taking the shortest route. What was possible in one or two cases should be possible in others, and it is well worth while to explore every conceivable way of making this method yield rapid and reliable results.[5]

[983] This application of the experiment shows that it is possible to touch upon a concealed, indeed an unconscious, complex by means of a stimulus-word; and, conversely, we may quite certainly assume that behind a reaction showing complex-characteristics a complex is hidden, even though the subject may strongly deny it. One must get rid of the idea that people with a good education and some insight can always recognize and admit their own complexes. Every human mind contains much that is not admitted and hence, as such, unconscious; and no one can boast that he stands completely above his complexes. He who nevertheless maintains that he can is not aware of the spectacles upon his own nose.

*

[984] It has long been believed that the association experiment enables one to distinguish certain *intellectual* types. This is by no means the case. The experiment does not give us any special insight into purely intellectual processes but rather into emotional ones. To be sure, we can establish certain types of reaction; they are not, however, based on intellectual peculiarities, but depend entirely on *emotional attitudes*. Educated subjects usually show trivial, well-canalized verbal associations, whereas the uneducated make more valuable, often more meaningful, associations. This behaviour would, from an intellectual point of view, be paradoxical. The associations, rich in content, offered by uneducated people are not really the products of a thinking rich in content but merely those of a particular emotional attitude. The whole thing is more important to the uneducated, his emotion is greater, and for that reason he pays more attention to the experiment than the educated person and his associations are therefore richer in content. Apart from those derived from a particular type of education, we have to consider four principal individual types:

1. An *objective type* with undisturbed reactions.

2. What is called a *complex type*, showing many disturbances in the experiment caused by the constellation of a complex.

3. What is called a *definition type*. This type always reacts with an explanation or a definition of the content of the stimulus-word, e.g.:

apple	a tree-fruit
table	a piece of furniture
to go for a walk	an activity
father	head of the family

[985] This type is chiefly found among stupid people, and it is therefore common among imbeciles. It can also be found in people who are not really stupid but who do not wish *to be taken as stupid*. Thus, a young student, whose associations were recorded by an intelligent older woman student, reacted entirely with definitions. The subject was under the impression that he was undergoing an intelligence test, and therefore focussed principally on the meaning of the stimulus-words; his associations, therefore, looked like those of a half-wit. Not all half-wits, however, react with definitions; probably the only ones who react in this way are those who would like to appear cleverer than they are—that is, those to whom their stupidity is painful. I call this complex, which we often meet with, the "intelligence-complex."

[986] This type often makes a strained and unnatural impression. They seem to be trying too hard:

anxiety	oppression of the heart
to kiss	love's release
to kiss	experience of friendship, etc.

These subjects want to be more than they are, they wish to exert more influence than they really have. Hence we see that people with an intelligence-complex are in general far from simple and free; that they are always somewhat unnatural and affected; that they show a predilection for complicated foreign words, high-sounding quotations, and other intellectual ornaments. It is in this sense that they want to influence their fellowmen, to impress others with their apparent education and intelligence, and thus to compensate for their painful feeling of stupidity.

[987] 4. The definition type is closely related to the *predicate type* or, more precisely, to the evaluating predicate-type. For example:

flower	beautiful
money	pleasant
animal	ugly
knife	dangerous
death	ghastly

In the definition type it is the intellectual significance of the stimulus-word that is emphasized, but in the predicate type it is its *emotional* significance. There are predicate types who greatly exaggerate, whose reactions may be such as these:

piano	horrible
to sing	heavenly
mother	deeply loved
father	something good, noble, holy

[988] In the definition type an absolutely *intellectual* attitude is manifested, or rather simulated, but here we have an attitude that is *full of feeling*. Yet, just as the definition type really means to conceal a lack of intelligence, so the exuberant *expression of feeling* conceals or overcompensates for a *deficiency of feeling*. This conclusion is illustrated in a very interesting way by the following discovery: Investigations of the influence of the family environment on association types reveal that young people seldom belong to the predicate type; in fact, the frequency of the predicate type increases with age. In women the increase of the evaluating predicate type begins a little after the fortieth year, and in men after the sixtieth. That is just the time when, owing to the decline of sexuality, considerable loss of feeling is in fact suffered.

[989] If a subject shows a distinct predicate type, one may always infer that a marked deficiency of feeling is thereby compensated. One must not, however, conclude conversely that a deficiency of feeling must produce a predicate type, any more than that idiocy directly produces a definition type. A predicate type can also betray itself through external behaviour, as, for example, through marked affectation, enthusiastic exclamations, a certain genteel, refined demeanour, and the affected language so often observed in "society."

[990] The complex type shows no particular tendency unless it be the effort to *conceal* complexes behind the disturbances of the experiment. The definition and predicate types betray a definite tendency to exert *some influence* on the experimenter. The definition-type tries to make an impact through his intelligence, whereas the predicate type displays his emotions. I need hardly add how important such observations are for the diagnosis of character.

[991] Having finished an association experiment, I usually add another experiment of a different kind, which I call *reproduction*. I repeat the same stimulus-words and ask the subjects whether they still remember their former reactions. In certain instances their memory fails and, as experience shows, such failures are brought about by stimulus-words that touch upon a feeling-toned complex, or by stimulus-words immediately following such critical words.

[992] This phenomenon has been said to be paradoxical and contrary to all experience. For it is known that feeling-toned matters are better retained in memory than things of no special significance. This is certainly correct, but

does not hold for the *linguistic* expression of a feeling-toned content. On the contrary, one very easily forgets what one has said under emotion, one is even apt to contradict oneself. Indeed, the efficacy of cross-examination in court depends on this fact. The reproduction-method therefore helps to emphasize the complex-stimulus still more. In normal people we usually find a limited number of incorrect reproductions, seldom more than 10 to 15 per cent, whereas in abnormal people, especially in hysteria, we often find from 20 to 40 per cent of incorrect reproductions. The uncertainty of reproduction is therefore in certain cases a measure of the emotivity of the subject.

[993] Most neurotics show a pronounced tendency to hide their intimate affairs in impenetrable darkness, even from the doctor, so that he finds it very difficult to form an accurate picture of his patient's psychology. In such cases my orientation is greatly assisted by the association experiment. When the experiment is finished, I first look over the general trend of the reaction-times. I see a great many very prolonged times; this means that the patient can only adjust himself with considerable disturbance.

[994] His psychological functions flow with marked internal friction, with resistances. Most neurotics react only with great and therefore very noticeable resistances; there are, however, others in whom the average reaction-times are as short as in normal subjects, and in whom the other complex-characteristics are lacking, although neurotic symptoms are undoubtedly present. These rather rare cases are found especially among very intelligent and educated, chronically ill people who, after many years of practice, have learned to control their outward behaviour and therefore display very few if any traces of their neurosis. Superficial observation would take them for normal, yet at some points they show disturbances that betray the repressed complex.

[995] After investigating the reaction-times I turn my attention to the type of association, to find out what type I am dealing with. If it is a predicate type I draw the conclusions on which I have already enlarged; if it is a complex-type I try to determine the nature of the complex. With the necessary experience one can free one's judgment from the subject's statements to quite an extent and, under certain circumstances, almost without any previous knowledge of him, can read the most intimate complexes from the results of the experiment. I first look for the reproduction-words and tabulate them; then I pick out the stimulus-words that show the greatest disturbances. In many cases, merely tabulating these words is sufficient to unearth the complex. In some cases, one is obliged

to put a question here and there. It may be best if I illustrate the point by means of a concrete example:

[996] The patient was an educated woman of thirty years of age, who had been married for three years. Since her marriage she had suffered periodically from states of agitation in which she was violently jealous of her husband. The marriage was in every other respect a happy one and in fact the husband gave no grounds for jealousy. The patient was sure that she loved him and that her agitated states were absolutely groundless. She could not imagine how this situation had come about and felt quite at a loss. It should be noted that she was a Roman Catholic and had been brought up to practise her religion, whereas her husband was a Protestant. This difference of religion was stated to be of no consequence. A more thorough anamnesis revealed an astounding prudishness: for instance, no one was allowed to talk in the patient's presence about her sister's confinement, because the sexual implication caused her the greatest agitation. She never undressed in her husband's presence but always in another room, and so on. At the age of twenty-seven she was supposed to have had no idea how children were born. Her association test gave the results shown in Fig. 8.

[997] The stimulus-words that stood out because of their strong disturbing effect were these: *yellow, to pray, to part, to marry, to quarrel, old, family, happiness, unfaithful, anxiety, to kiss, bride, to choose, contented*. The following stimulus-words produced the strongest disturbances: *to pray, to marry, happiness, unfaithful, anxiety*, and *contented*. These then are the words that clearly pointed towards the complex. The conclusion that can be drawn from this is: that she was not indifferent to the fact that her husband was a Protestant, that she was again thinking about prayer and felt there was something wrong with the married state; that she was unhappy; she was false—that is, she was having fantasies about being unfaithful; she suffered from anxiety (about her husband? about the future?); she was dissatisfied with her choice *(to choose)* and was thinking about *parting*. The patient therefore had a divorce-complex, for she was very dissatisfied with her married life. When I told her this result she was very shaken and at first tried to deny it, then to gloss it over, but finally she gave in and admitted it. Moreover, she produced a great deal of material, consisting of fantasies about being unfaithful, reproaches against her husband, and so on. Her prudishness and jealousy were merely a projection of her own sexual wishes onto her husband. She was jealous of her husband because she herself was unfaithful in fantasy and could not admit it to herself.

[998] It is impossible in a lecture to give a review of all the practical applications of the association experiment. I must be content with having put before you at least the main points.

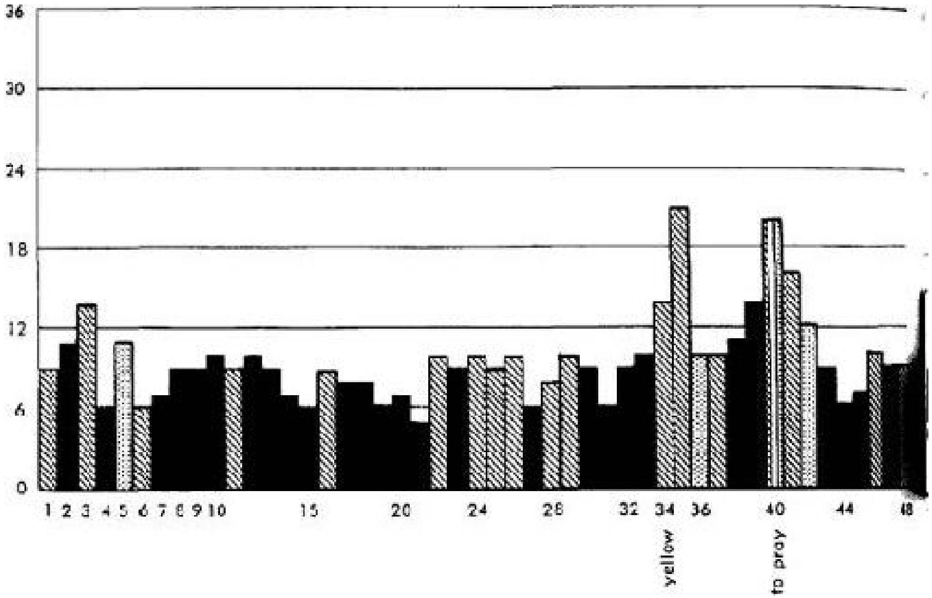

FIG. 8. Columns that are shaded ▨ = incorrect reproductions; ☐ = repetitions of the stimulus-words; ▒ = associations where the patient either laughed or made a slip of the tongue and where she used several words instead of one. The heights of the columns represent the length of the reaction-time. For the stimulus-words corresponding to the numbers, see the list in par. 941*

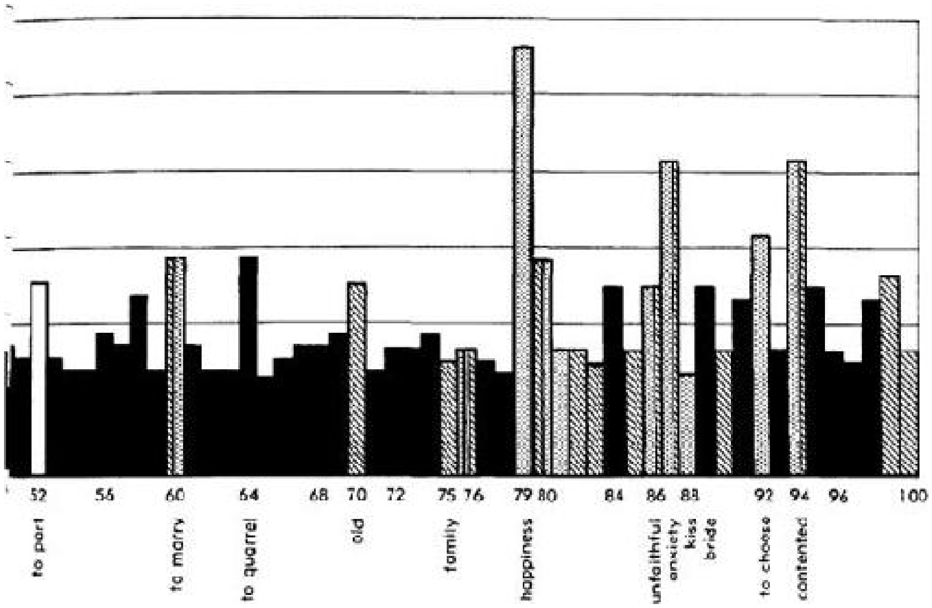


THE FAMILY CONSTELLATION[1]

[999] *Ladies and Gentlemen:* As we have seen, there are many different ways in which the association experiment may be used in practical psychology. I should like to talk to you today about yet another use of this experiment, one that is, in the first place, of merely theoretical importance. My pupil, Doctor Fürst,[2] made the following investigations: she applied the association experiment to twenty-four families, consisting altogether of one hundred subjects. The resulting material amounted to 22,200 associations. This material was processed as follows.

1000] Fifteen clearly defined groups were formed according to logical-linguistic criteria and the associations were arranged as follows:[3]

	Husband	Wife	Difference
I. Co-ordination	6.5	0.5	6
II. Sub- and supraordination	7	–	7
III. Contrast	–	–	–
IV. Predicate expressing a personal judgment	8.5	95.0	86.5
V. Simple predicate	21.0	3.5	17.5
VI. Relations of the verb to the subject or complement	15.5	0.5	15.0
VII. Designation of time, etc.	11.0	–	11.0
VIII. Definition	11.0	–	11.0
IX. Coexistence	1.5	–	1.5
X. Identity	0.5	0.5	–
XI. Motor-speech combination	12.0	–	12.0
XII. Composition of words	–	–	–
XIII. Completion of words	–	–	–
XIV. Clang associations	–	–	–
XV. Defective reactions	–	–	–
Total	–	–	173.5

$$\text{Average difference } \frac{173.5}{15} = 11.5$$

1001] As can be seen from this example, I utilize the difference to demonstrate the degree of the analogy. In order to find a basis for the sum of the resemblance I have calculated the differences among all Dr. Fürst's subjects, not related among themselves, by comparing every female subject with all the other unrelated females; the same comparison has been made for the male subjects.

1002] The most marked difference is found in those cases where the two subjects compared have no associative quality in common. All the groups are calculated in percentages, the greatest difference possible being $\frac{200}{15} = 13.3$ per cent.

I. The average difference of male unrelated subjects is 5.9 per cent, and that of females of the same group is 6 per cent.

II. The average difference between male related subjects is 4.1 per cent, and that between female related subjects is 3.8 per cent. From these numbers we see that relatives show a tendency to agreement in the reaction type.

III. Difference between fathers and children = 4.2.
” ” mothers ” ” = 3.5.

The reaction types of children come nearer to the type of the mother than to the father.

IV. Difference between fathers and their sons = 3.1.
” ” ” ” ” daughters = 4.9.
” ” mothers ” ” sons = 4.7.
” ” ” ” ” daughters = 3.0.

V. Difference between brothers = 4.7.
” ” sisters = 5.1.

If the married sisters are omitted from the comparison we get the following result:

Difference of unmarried sisters = 3.8.

These observations show distinctly that marriage destroys more or less the original agreement, as the husband belongs to a different type.

Difference between unmarried brothers = 4.8.

Marriage seems to exert no influence on the association forms in men. Nevertheless, the material that we have at our disposal is not as yet enough to allow us to draw definite conclusions.

VI. Difference between husband and wife = 4.7.

This number sums up inadequately the different and very unequal values; that is to say, there are some cases which show an extreme difference and some which show a marked concordance.

1003] The different results are shown in the graphs (Figs. 1–5). In the graphs I have marked the number of associations of each quality perpendicularly in percentages. The roman numbers written horizontally represent the forms of association indicated in the table above.

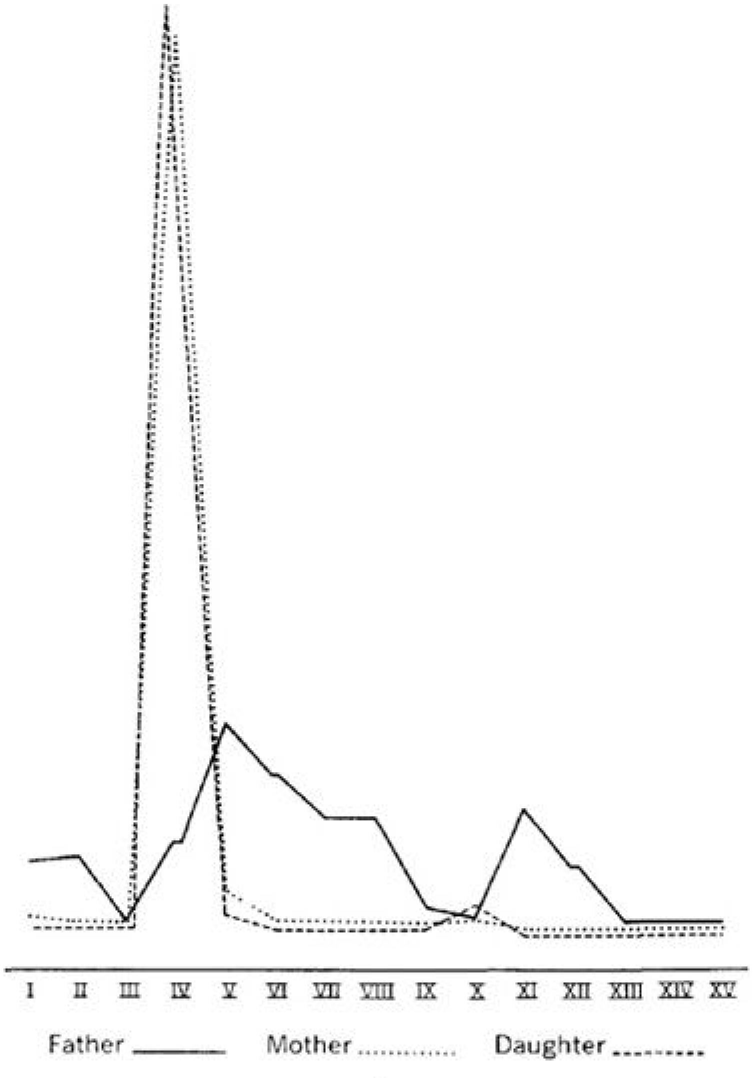
1004] The similarity of associations of related subjects is often quite extraordinary. I will give you the associations of a mother and daughter:

Stimulus-word	*Mother*	*Daughter*
to pay attention	hard-working	pupil
law	God’s commandment	Moses
dear	child	father and mother
great	God	father
potato	tuber	tuber
family	many people	five people
strange	traveller	travellers
brother	dear to me	dear
to kiss	mother	mother
a burn	great pain	painful
door	wide	big
hay	dry	dry
month	many days	31 days
air	cool	moist
coal	sooty	black
fruit	sweet	sweet
merry	happy child	little children
etc.	etc.	etc.

1005] One might indeed think that in this experiment, where the door is thrown wide open to so-called chance, individuality would become a factor of the utmost importance, and that therefore one might expect a rich variety and freedom of association. But, as we have seen, the opposite is the case. The daughter shares her mother’s way of thinking, not only in her ideas but also in her form of expression; so much so that she even uses the same words. What is more free, fickle, and inconsequent than a passing thought? It is not inconsequent, however, nor free, but strongly determined within the boundaries of the environment. If, therefore, even the most superficial and apparently most fleeting mental images are entirely due to the constellation of the environment, what must we not expect for the more important mental activities, for emotions, wishes, hopes, and intentions? Let us consider a concrete example, illustrated by Fig. 1.

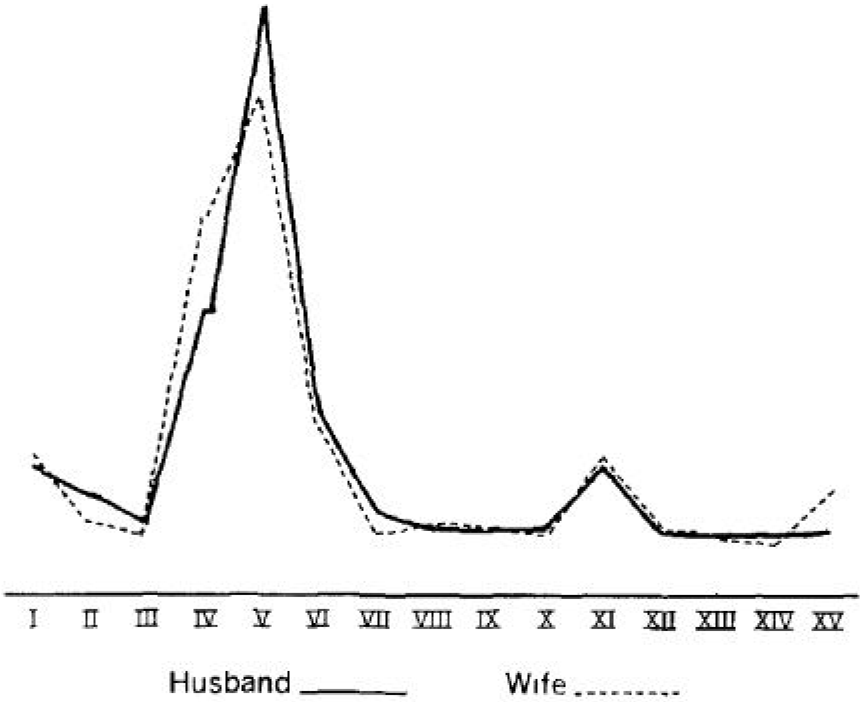
1006] The mother is forty-five years old and the daughter sixteen. Both are very distinct evaluating predicate types and differ from the father in the most striking manner. The father is a drunkard and a demoralized person. It is understandable therefore that his wife is emotionally starved and betrays this by her intense value judgments. The same reasons cannot, however, apply to the daughter for, in the first place, she is not married to a drunkard and, in the second place, life with all its hopes and promises still lies before her. It is quite unnatural for the daughter to appear as an extreme evaluating predicate type. She responds to the stimuli of the environment precisely as her mother does. But whereas, in the mother, the type is to some extent a natural consequence of her unhappy situation, this simply does not apply to the daughter. The daughter merely imitates her mother; she follows her mother’s pattern. Let us consider what this can mean for a young girl. It is unnatural and forced for her to react to the world like an older woman who is disappointed in life. But it could be even more serious than this. As you know, evaluating predicate types overtly express intense emotion; for them everything is emotional. If such people are close to us it is difficult to avoid responding, at least inwardly; we may become infected and even carried away by them. Originally the affects and their physical manifestations had a biological significance; that is, they were a protective mechanism for the individual and the whole herd. If we show feeling, we can be sure that we shall evoke feeling in others. That is the experience of the evaluating predicate type. What the forty-five-year-old woman lacks emotionally, love within her marriage, she seeks compensation for in the outside world, and for this reason she is an ardent follower of the Christian Science movement.

If the daughter follows this pattern she is behaving like her mother, looking for emotional satisfaction from outside. But for a girl of sixteen such an emotional state is, to say the least, very dangerous; like her mother, she is reacting to her environment, soliciting sympathy for her suffering. Such an emotional state is no longer dangerous in the mother, but for obvious reasons it is for the daughter. Once she frees herself from her father and mother she will be like her mother, an inwardly dissatisfied suffering woman. She will thus be exposed to the great danger of falling a victim to brutality and of marrying a brute and inebriate like her father.



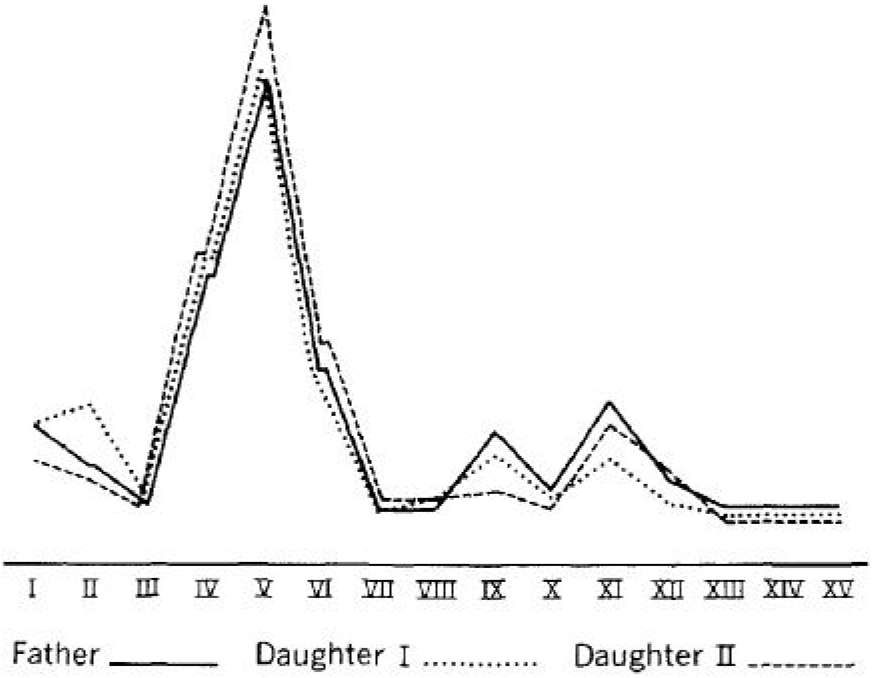
1

Fig. 1. The father (solid line) shows an objective type, while the mother and daughter show the pure predicate type with a pronounced subjective tendency.



2

Fig. 2. The husband and wife agree well in the predicate objective type, the predicate subjective being somewhat more numerous in the wife.



3

Fig. 3. A very nice agreement between a father and his two daughters.

4

Fig. 4. Two sisters living together. The dotted line represents the married sister.

5

Fig. 5. Husband and wife. The wife is a sister of the two women of Fig. 4. She approaches very closely to the type of her husband. Her tracing is the direct opposite of that of her sisters.

1007] This consideration seems to me important for the understanding of the influence of environment and of education. The example shows what may be transmitted from a mother to her child. It is not pious precepts nor the repetition of pedagogic truths that have a moulding influence on the character of a developing child; what most influences him are the unconscious personal affective states of his parents and teachers. Hidden conflicts between the parents, secret worries, repressed wishes, all these produce in the child an emotional state, with clearly recognizable signs, that slowly but surely, though unconsciously, seeps into his mind, leading to the same attitudes and hence the same reactions to the environment. We all know that when we are with moody and melancholy people we ourselves become depressed. A restless and nervous person infects the people around him with uneasiness, a grumbler with his discontent, and so on. Since adults are so sensitive to surrounding influences, we should certainly expect this even more among children, whose minds are as soft and malleable as wax. Fathers and mothers deeply impress their children's minds with the stamp of their personalities; the more sensitive and impressionable the child the deeper the impression. Everything is unconsciously reflected, even those things that have never been mentioned at all. A child imitates gestures and, just as the parents' gestures are the expressions of their emotional states, so in turn the gesture gradually produces an emotional state in the child, as he makes the gesture his own. His adaptation to the world is the same as his parents'. At puberty, when he begins to free himself from the spell of the family, he goes out into life with, more or less, the same kind of compromise-adaptations as those of his parents. The frequent and often very deep *depressions of puberty* arise from this; they are symptoms rooted in the difficulties of new adjustments. The adolescent at first tries to become as separate as possible from his family; he may even estrange himself from them, but inwardly this only binds him the more firmly to his image of his parents. I remember the case of a neurotic young man who ran away from home. He was estranged from and almost hostile to his family, but he admitted to me that he possessed a very special talisman; it was a casket containing his old childhood books, old dried flowers, stones, and even small bottles of water from the well at his home and from a river along which he used to walk with his parents.

1008] The first moves towards friendship and love are constellated in the strongest possible manner by the nature of the relationships with our parents, and here as a rule one can see how powerful is the influence of the family constellation. It is not rare, for instance, for a healthy man whose mother was hysterical to marry a hysteric, or for the daughter of an alcoholic to choose an alcoholic for her husband. I was once consulted by an intelligent and educated young woman of twenty-six who suffered from a peculiar symptom. She complained that her eyes now and then took on a strange expression that exerted an undesirable influence on men. If she looked at a man he became self-conscious, turned away and suddenly said something to the man next to him, whereupon they either laughed or looked embarrassed. The patient was convinced that her glance excited indecent thoughts in men. It was impossible to talk her out of her conviction. This symptom immediately made me suspect that I was dealing with a case of paranoia rather than with a neurosis. But only three days of further treatment showed me that I was mistaken, for the symptom promptly disappeared after it had been analyzed. It arose like this: the lady had had a lover who had publicly jilted her. She felt utterly forsaken, withdrew from all society and amusements, and developed suicidal ideas. In her isolation, unconscious and repressed erotic wishes accumulated and these she unconsciously projected on to men whenever she was in their company. This gave rise to the conviction that her look excited erotic wishes in men. Further investigation showed that her unfaithful lover was mentally ill, a fact that she had apparently not realized. I expressed my astonishment at her making such an unsuitable choice, and added that she must have had a certain inclination to love mentally abnormal people. This she denied, stating that she had once before been engaged to be married, to a perfectly normal man. He, too, deserted her; and on further inquiry it was found that he, too, had shortly before been in a mental hospital for a year—another psychotic! This seemed sufficiently to confirm my view that she had an unconscious tendency to choose insane people. Where did this strange taste come from? Her father was an eccentric and in his later years was completely alienated from his family. Her love had therefore been displaced from her father on to a brother eight years her senior, whom she loved and honoured as a father. At the age of fourteen this brother became hopelessly insane. This was apparently the pattern from which the patient could never free herself, according to which she chose her lovers, and through which she was bound to become unhappy. The particular form of her neurosis, which gave the impression of insanity, probably arose from this childhood pattern. We must take into consideration that in this case we are dealing with a highly educated and intelligent woman, who was not inattentive to her inner experiences, who indeed pondered a great deal over her unhappy fate, without, however, having any idea of what caused her misfortunes.

1009] This is the kind of thing that we unconsciously take for granted in ourselves; for this very reason we cannot see what is going on but put the blame on what we think of as our innate character. I could give any number of examples of this. Patients constantly illustrate for me the determining influence of the family background on their destiny. In every neurosis we can see how the emotional environment constellated during infancy influences not only the character of the neurosis, but also the patient's destiny even down to its very details. Many an unhappy choice of profession and disastrous marriage can be traced to such a constellation. There are, however, cases where the profession has been well chosen, where the husband or wife leaves nothing to be desired, and still the patient feels uneasy and lives and works under constant difficulties. Such cases often appear to be chronic neurasthenics. Here the difficulty is that the mind is unconsciously split into two parts, of divergent and conflicting tendencies; one part lives with the husband or the profession, while the other lives unconsciously in the past with father or mother. I have treated a woman who suffered for many years from a severe neurosis which deteriorated into dementia praecox. The neurotic illness began with her marriage. Her husband was kind, educated, well-to-do, in every respect suitable for her; his character showed nothing that should in any way interfere with a happy marriage. The marriage was nevertheless unhappy, all easy companionship was impossible because the wife was neurotic.

1010] The heuristically important principle of every psychoanalysis runs: *If someone develops a neurosis, this contains the negative aspect of his relationship with the person closest to him*. A neurosis in a husband clearly shows that he has strong resistances and negative attitudes towards his wife; in a neurotic wife there is an attitude that drives her away from her husband. In an unmarried patient the neurosis turns against the lover or the parents. Every neurotic naturally resists such a relentless interpretation of the content of his neurosis and often refuses on any account to recognize it, and yet this is always the heart of the matter. Certainly, the conflict does not lie on the surface, but can as a rule only be uncovered by laborious psychoanalysis.

1011] Here is the history of our patient: The father was an impressive personality. She was his favourite daughter and held him in boundless veneration. At the age of seventeen she first fell in love with a young man. At that time she twice dreamt the same dream, the impression of which never afterwards left her; she even imputed a mystical meaning to it and often remembered it with religious awe. In the dream she saw a tall masculine figure with a very beautiful white beard, at the sight of which she was filled with a feeling of awe and delight as if she were experiencing the presence of God himself. This dream made the deepest possible impression on her, and she was compelled to think about it for ever after. The love-affair proved not to be a serious one and soon came to an end. Later the patient married her present husband. Though she loved her husband she was always, in her thoughts, comparing him with her late father, and the comparison always turned against her husband. Whatever the husband did, said or intended was judged by this standard and always with the same result: "My father would have done all this differently and better." Thus our patient could not enjoy life with her husband. She could neither respect nor love him enough and was inwardly disappointed and unsatisfied. She gradually developed strong religious feelings and at the same time marked hysteriform symptoms arose. She began by having sentimental attachments to one clergyman after another; she was looking everywhere for a soul-mate and estranged herself more and more from her husband. The mental illness became manifest about ten years after their marriage, and in this condition she refused to have anything to do with her husband and child; she imagined herself to be pregnant by another man. The resistance to her husband, which had hitherto been laboriously repressed, became quite outspoken and showed itself in various ways, among other things in violent abuse.

1012] This case shows the onset of a neurosis approximately at the moment of marriage; that is, it expresses the negative attitude to the husband. What is the content of the negative attitude? It is the relationship with the patient's father, for day by day she proved to herself that her husband did not come up to her father's stature. When the patient first fell in love a symptom appeared, an extremely impressive dream or vision. She saw the man with the very beautiful white beard. Who was this man? When her attention was drawn to the beautiful white beard she immediately recognized the image. It was, of course, her father. Every time the patient began to fall in love, the image of her father arose disturbingly and so prevented her from adapting herself to a relationship with the man in question.

1013] I purposely chose this case as an example because it is a simple, obvious, and thoroughly typical one of a marriage crippled through the wife's neurosis. I could tire you out with similar examples. The misfortune is always too strong an attachment to the parents, so that the child remains imprisoned in its infantile relationships. It should be one of the most important aims of education to free the growing child from his unconscious attachment to the influences of his early environment, in such a way that he may keep what is valuable in it and reject whatever is not. It seems to me impossible at present to solve this difficult question by starting from the child's end. We know as yet too little about children's emotional processes. The first and only contribution to the literature giving actual evidence on this subject has in fact been published this year. It is the analysis of a five-year-old boy by Freud.[4]

1014] Children's difficulties are very great. Parents' difficulties, however, should not be so great. Parents could in many ways use more discretion and more forbearance towards their children's love. The sins committed against favourite children by their parents' over-indulgence could perhaps be avoided through a wider knowledge of the child's mind. I find it for many reasons impossible to say anything universally valid about the educational aspect of this problem. We are as yet a long way from general precepts and rules; we are still doing field work shown in case-histories. Unfortunately, our knowledge of the subtler processes of a child's mind is so inadequate that we are not yet in any position to say where lies the greater fault: in the parents, the child himself, or in environmental attitudes. Only psychoanalyses like the one published by Professor Freud in our *Jahrbuch*, 1909,[5] will help us out of this difficulty. Such detailed and thorough observations should be a strong inducement to all teachers to acquaint themselves with Freud’s psychology. In this psychology educationists can find far more than in the current physiological psychology.

II

PSYCHOPHYSICAL RESEARCHES

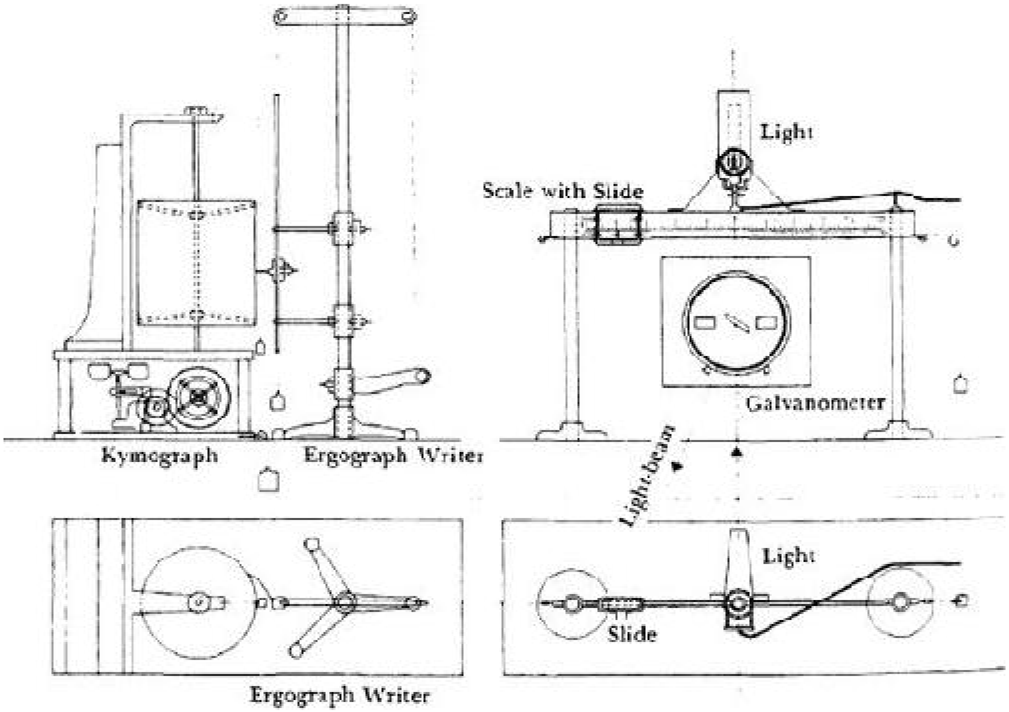
ON THE PSYCHOPHYSICAL RELATIONS OF THE ASSOCIATION EXPERIMENT[1]

1015] At the second German Congress for Experimental Psychology, held at Würzburg (18–21 April 1906), Dr. Veraguth, privatdocent in neurology at Zurich, reported upon a galvanic phenomenon, which he called "galvano-psychophysical reflexes." The author conducts a current of low tension (about two volts) through the human body, the places of entrance and exit of the current being the palms. He introduces into the circuit of the current a Deprez-d'Arsonval galvanometer of high sensitivity, and also a shunt for lowering the oscillations of the mirror. With this technique, if one applies to a subject tactile, optic, or acoustic stimuli of a certain strength, the galvonometer will indicate an increase in the amount of the current, i.e., a lowering of the electrical resistance of the body. Very early in the course of these experiments it was discovered that the action of the galvanometer was not in direct relation with the strength of the stimulus but rather with the intensity of the resulting psychological feeling-tone. Of great interest is the fact that the irregularity of the galvanometer did not appear at the same moment as the perception of the stimulus, but after a latent period of one to six seconds.

1016] Somewhat later Veraguth observed that a movement (often of great intensity) occurred when the stimulus, instead of being actually applied, was merely announced to the subject. This phenomenon he terms "oscillation through expectation" *(Erwartungsschwankung)*. From these observations Veraguth concludes that in this experiment *feelings* are *objectively represented*. The only difficulty in this procedure lies in the technique of the registration of galvanometric oscillations.

1017] Veraguth takes photographs of the curve of the mirror's movements on a rotating film; but this method is rather difficult and expensive, and only short curves can be obtained, while for the graphic representation of feelings long curves are desirable. I have therefore constructed an apparatus by means of which curves of more than thirty to sixty feet can be taken. In such considerable periods of time many and different experiments can be made without difficulty.

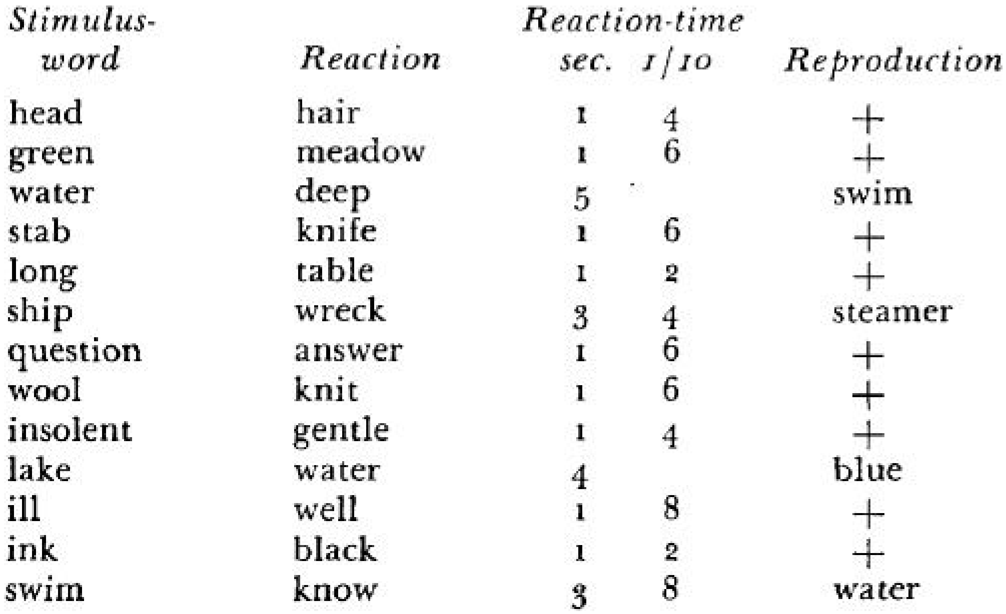
1018] The principle of my apparatus is as follows: I add to the scale a movable slide with a visor. The slide, pushed forward by the hand, always follows the moving mirror-reflection. After some practice, this manoeuvre can be made very easily and exactly. To the slide is fastened a cord leading to what is called an ergograph writer, which marks the movements of the slide on a kymographic tambour fitted with endless paper, upon which the curves are drawn by a pen-point (see illustration).



For measuring the time one may use a Jaquet chronograph, and for indicating the moment of stimulus an ordinary electric marker.

1019] With these arrangements I am able to take long curves that are especially valuable for representing feeling-tones aroused by the association experiment.

1020] As is perhaps already known, I have clearly demonstrated in the Diagnostic Association Studies[2] that strong feeling-tones often accompany the association and cause characteristic and regular disturbance in the association processes. I conduct my experiment as follows: I call a series of stimulus-words to a subject who is requested to answer as quickly as possible, saying the first word that comes into her mind. I measure the time elapsing between the stimulus-word and the reaction (the “reaction-time”). Having noted a rather large number of reactions (about one hundred), I then make the subject repeat, one by one, the answers to the stimulus-words (this I call the “reproduction method”). What will occur during such an experiment I shall illustrate by an example.[3]



Stimulus-word	*Reaction*	*Reaction-time*		*Reproduction*
		sec.	*1/10*	
head	hair	1	4	+
green	meadow	1	6	+
water	deep	5		swim
stab	knife	1	6	+
long	table	1	2	+
ship	wreck	3	4	steamer
question	answer	1	6	+
wool	knit	1	6	+
insolent	gentle	1	4	+
lake	water	4		blue
ill	well	1	8	+
ink	black	1	2	+
swim	know	3	8	water

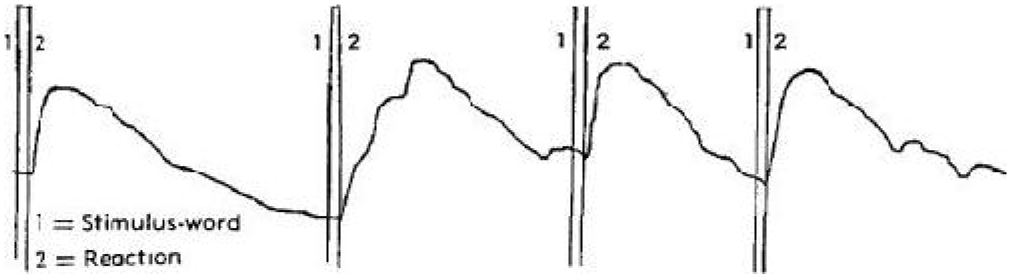
1021] In considering the reactions of this subject we find at first sight nothing remarkable. She has, with some few exceptions, relatively short reaction-times, and there are also a few incorrect reproductions. But on looking closer we discover that the reactions after *water, ship, lake, swim*, were followed by a rather long reaction-time; and at the same time we observe that with these reactions the following reproduction is incorrect.

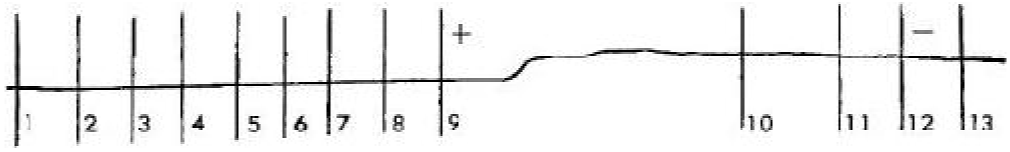
1022] So far as we know, we may suppose that the words *water, ship*, etc., awoke lively feelings that retarded the reaction. The incorrect reproduction of the reactions is also caused, as we can prove by experience, by the interference of lively feelings. The feelings causing such phenomena are generally of a disagreeable nature and we therefore venture to suppose that these stimulus-words gave rise to a complex of ideas having some relation to water and possessing great importance for the subject. The subject, cautiously questioned, tells us that a short while ago while living through most painful and exciting experiences she had seriously thought, in a moment of desperation, of *committing suicide by drowning herself*. But as the days began to look brighter her destiny did not bring her to such an untimely end.

1023] The complex of the intention to commit suicide, to which strong feelings are attached, betrayed itself by different psychological disturbances in the experiment. In the same or in similar fashion, all other complexes connected with the affections might naturally betray themselves. Hence the association experiment is a good means of fathoming and of analyzing the personality. According to the opinion of some German authors this method should be used to trace the guilt complexes of criminals who do not confess. At the present time many experiments are being carried out along these lines in Germany, experiments that have been of great scientific interest, but which have not, so far, produced results of undoubted practical value.[4]

1024] With this experiment, however, apparently so simple, there is one great difficulty—namely, the interpretation of the disturbances; or, to express it another way, what sort of complexes are they that cause these disturbances ("indicators of complexes")? In reply to this question we may say that it is the *routine* of the experiments that is the main thing; and, in view of this fact, we suggest that the interpretation is at present rather an art than a science. In the future, perhaps, laws will be found for the method of interpretation. He who has not mastered this routine may easily make a wrong suggestion and thus go astray. This reproach, and especially that of arbitrary interpretation, has been made concerning my analysis; and consequently every means that helps to define the complex and its feeling-tone is useful. The "galvano-psychophysical reflex" would seem to be such a means.

1025] By representing graphically the galvanic oscillations during the association experiment, we occasionally obtain curves of very great interest, of which I wish to give some few examples. (The vertical strokes indicate the moment at which the stimulus-word was given.) It can be seen that, shortly after the preceding reaction, the curve quickly rises and then slowly falls again. In this case every reaction is succeeded by a movement of the galvanometer. If by a special proceeding we diminish the sensibility of the apparatus, only the most intensive feeling-tones influence the current, so that occasionally we shall obtain very distinct curves that show the strong feeling-tone in a specially clear manner. The following is such an example:





In the beginning we see the curve making its way horizontally without any irregularity. In this phase come the following eight reactions:

1. hot	cold
2. hand	foot
3. apple	fruit
4. naughty	angry
5. mouth	teeth
6. wake	wake up
7. drink	eat
8. bed	sleep

These reactions show nothing of interest; their feeling-curve accordingly goes in a horizontal line.

9. pretty	not pretty
10. danger	no danger
11. to call on	not to call on
12. workman	workwoman

1026] These reactions are obvious:

1. The first three are uttered in two words, which is, as a rule, unusual with this subject.

2. There are obvious and for the most part contrasting associations that are not easily intelligible.

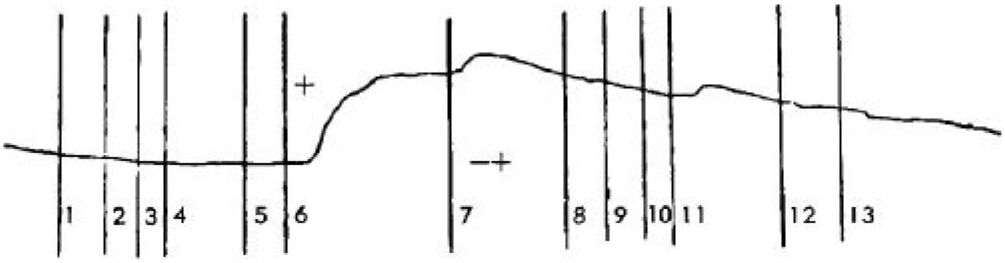
3. A striking perseveration in the linguistic form is to be seen, beginning with *not pretty. Workman / workwoman* is rather a superficial association.

1027] It is evident that this strange phase takes its origin in *pretty*. On the curve we can see, beginning with the reaction *not pretty*, the appearance of a strong feeling-tone that lasts for a long time and disappears only with the last reaction. The linguistic perseveration *(not pretty, no danger, not to call on)* is therefore connected with a feeling, lasting probably through the same period.

1028] I had suspected from the beginning that the young man had a sweetheart. He told me that he had been married the week before. Upon my asking him whether his wife were pretty, he very characteristically replied, “Other people do not find her very pretty, but for me she is quite pretty enough.” From this it is evident that the word *pretty* had hit upon a sore point.

1029] The next curve illustrates a very interesting case. The subject is a young, diligent, and gentle man, of whom I knew nothing, except the fact of his being an abstainer.

1030] In the beginning we note the curve falling slowly, then taking a rather horizontal course until the sixth stimulus-word, where a sudden steep rise sets in and maintains itself until the thirteenth reaction.



1031] The reactions are as follows:

1. pay	money

2. snake	animal
3. fine	beautiful
4. love	hatred
5. help	assist
6. *restaurant*	*non-alcoholic*

With the sixth reaction the rising of the curve begins. The reaction *non-alcoholic* indicates a very individual complex of ideas. And a very strong feeling seems to be attached to the fact that he is a teetotaler.

1032] The reaction next following is:

7. *polished*	*glass*

accompanied by a new rise of the curve. *Glass* might be another association of the *restaurant* complex. The next associations are:

8. soldier	military
9. write	letter
10. looking-glass	clear

which present nothing special and are also galvanically uninteresting.

11. *full*	*man*

(The German word *voll*, ‘full’, has also the occasional meaning ‘completely drunk’.) This association, which distinctly indicates the idea of being drunk, is again accompanied by a rising of the curve. The next association is:

12. intelligence	prudent

1033] As things present themselves we may be right in supposing that there is a complex with strong feelings that has some relation to *restaurant* and *drunkenness*. When asked, the man confesses that once, when drunk, he had committed the crime of a serious assault and had consequently been sentenced to a long term of imprisonment. Because of these occurrences he had become an abstainer as a means of preventing his again getting into a similar situation. (This confession was corroborated by others as being the truth.)

1034] As may easily be understood, this event left a serious and lasting impression, deepened by the fact that his former crime had become a great social hindrance to him.

1035] These examples may serve to show that the association experiment is, under certain conditions, a suitable way of demonstrating the feeling-tones that accompany the associations. I say “under certain conditions”—for not always will one succeed in obtaining such clear and distinct curves as those shown above. The experiment possesses numerous complications, to overcome which a great deal of time and work is required. There is moreover the difficulty that the physical and physiological part of the experiment is still obscure, notwithstanding the work of Tarchanoff, Sticker, Sommer, and Veraguth. At the present time, Binswanger in Zurich is occupied with these researches. I will not here anticipate his work, which he has already finished.[5]

PSYCHOPHYSICAL INVESTIGATIONS WITH THE GALVANOMETER AND PNEUMOGRAPH IN NORMAL AND INSANE INDIVIDUALS[1]

by Frederick Peterson and C. G. Jung

1036] These investigations were carried out in the laboratory of the Clinic for Psychiatry at Zurich, to the director of which, Professor E. Bleuler, we are under obligation for the use of apparatus and material for study. The purposes of our research were to ascertain the value of the so-called “psycho-physical galvanic reflex” as a recorder of psychical changes in connection with sensory and psychical stimuli; to determine its normal and pathological variations; to study the respiratory innervation curve in the same relations; and finally to compare the galvanometric and pneumographic curves taken simultaneously upon the kymograph, under the influence of various stimuli. In word-associations the reaction-time was also registered for further comparison.

I. APPARATUS EMPLOYED

1037] For the respiratory curve we used the Marey pneumograph made by Zimmerman, in Leipzig. The kymograph was made by Schüle, in Basel, and runs with a weight, making it both steady and noiseless. The stop-watch employed for reaction-time was manufactured by Billian, of Zurich.

1038] The use of the galvanometer in experimental psychology is so new and recent as to require a special description and a brief review of the scanty literature of the subject.

The first to discover the influence of mental conditions on the galvanometer was Professor Tarchanoff, who published a paper in *Pflüger’s Archiv für Physiologie*, 1890, entitled “Galvanic Phenomena in the Human Skin in Connection with Irritation of the Sensory Organs and with Various Forms of Psychic Activity.” He employed tubular unpolarizable clay electrodes, connected with the skin by means of hygroscopic cotton pads, 10 to 15 cm. long, saturated with saline solution. These are attached to a Meissner and Meyerstein galvanometer. Deviations of the mirror were noted through a telescope upon a scale three metres distant from the galvanometer. The scale was divided on each side of the zero point into 50 cm. and these again into mm. The galvanometer was so sensitive that a nerve-stream of a frog’s sciatic nerve deflected the mirror so much that all the divisions on the scale were passed over. The electrodes were applied at various times to different portions of the body, such as the hands and fingers, feet and toes, the face, the nose, the ears and the back. Experimenting thus, he obtained the following results:

1039] Light tickling of the face, ears, or soles of the feet, with a camel-hair brush or a feather, induced, after a latent period of from one to three seconds, a deflection in the galvanometer to the extent of the whole 50 cm. of the scale. The same results were obtained by stimulating the skin with the faradic brush, with hot and cold water, and by pricking with a needle. Stimulation in analogous ways of other sensory organs, the ear, the nose, the tongue and the eye, affected the galvanometer in a corresponding manner.

1040] The experimenter then ascertained that actual stimulation was not essential to these results, but the presentation of the proposed stimulus to the imagination also brought about similar deviations in the galvanometer. He stated, furthermore, that the recollection of some fear, fright, or joy, in general any kind of strong emotion, produced the same result. The next point of interest recorded by Tarchanoff was that ordinary abstract mental exercise, such as computation, does not affect the galvanometer unless the exercise be accompanied by exertion. He also noted that the motion of expectant attention or anticipation had a marked effect upon the galvanometer. Tarchanoff regarded the phenomena he observed as due to a secretory current of electricity associated with the sweat-glands. He was evidently unaware of the extraordinary value of the investigations he described in this brief paper. Like many discoveries of importance, his remarkable work lay buried in medical literature for years, and it was not until 1897 that any further contribution on this subject appeared. In that year, Sticker[2] records a repetition of the work of Tarchanoff. His conclusion was that the capillary system of blood-vessels was a factor in the perturbations of the galvanic current. He opposed Tarchanoff's idea of the centripetal excitation of a secretory current, because he found that the same deviations were noted when the electrodes were applied to anaesthetic and analgesic areas of skin (functional or organic).

1041] After a lapse of five years, Sommer[3] made some experiments with the galvanometer, but lost himself in technical and physical details, and failed completely to grasp the intrinsically valuable features of the instrument. He observed fluctuations which he attributed to alterations in resistance of the skin or to changes in contact between skin and electrodes. He thought any apparent psychic influence was due to involuntary muscular contractions induced by increased pressure on the electrodes, and concluded that, except for the reaction to tickling, no psychic influence on the galvanometer could be established with certainty. He therefore stumbled over, but missed, the one essential point.

1042] About two years ago E. K. Müller, an electrical engineer, of Zurich, read a paper before the Swiss Society of Natural Sciences (medical section) on “The Influence of Psychic and Physiological Phenomena upon the Electrical Conductivity of the Human Body.” Happening to make certain experiments upon himself in relation to the resistance of the human body in the alternating magnetic field, he rediscovered the deflectibility of the mirror-galvanometer under psychic and nervous stimulation as established by Tarchanoff.

1043] O. Veraguth, a neurologist, of Zurich, was then led by Müller to experiment in the same direction. He made use of the Deprez-d'Arsonval mirror-galvanometer, nickel-plated brass cylinders for electrodes, a feeble electrical current, a horizontal celluloid scale on which the light from the mirror registered its movements, and an apparatus for photographic delineation of the fluctuations. He published some results last August (1906) in the *Archives de psychologie* (Geneva), and he gave the name "psychophysical galvanic reflex" to the phenomenon.[4] Veraguth corroborates the findings of Tarchanoff. One or two of his experiments are especially striking. If the individual under observation is read to, deviation of the mirror is noted when passages associated with emotional tone are reached. Or, if a series of unrelated words is pronounced, a test suggested to him by one of the authors of this paper (Jung), words connected with some emotional complex produce an effect on the galvanometer, while indifferent words have no effect. He concludes from his studies that only such stimuli as are associated with sufficiently intense and actual emotional tone induce a deviation in the galvanometer. He states in his paper that he is not yet in a position to explain the phenomenon, but that if change in resistance were the cause then manifold contradictions are presented to our present conceptions of resistance in the human body. He did not think it due to alterations in the quantity of blood in the parts beneath the electrodes, for the phenomenon takes place whether the hands be emptied of blood by an Esmarch bandage or supercharged with blood by artificial venous stasis. Veraguth excludes the participation of the perspiration, for the results were similar in hands made dry by formalin.

1044] As far as we know the above review covers the scanty literature of the subject, but work has been carried on for about a year in this field in the laboratory of the Psychiatric Clinic at Zurich, the most of which has not yet been published. One of us (Jung) has published in the *Journal of Abnormal Psychology* (Boston), for February 1907, the results of association experiments in which the galvanometer was employed, and in this article is a drawing of the apparatus and a description of the order of research.[5] In the same laboratory, L. Binswanger, together with Jung, has investigated the physical and physiological problems presented by the phenomenon, the results of which will shortly be published in a separate paper,[6] though the material conclusions of their investigations are embodied in this paper.

1045] The apparatus employed by us is as follows: the mirror galvanometer of Deprez-d'Arsonval; a translucent celluloid scale divided into millimetres and centimetres with a lamp upon it (made by Zulauf & Co., of Zurich), the scale being placed one metre from the galvanometer; a moveable indicator sliding on the scale and connected by a device of Jung with a recording pen writing upon the kymograph; a rheostat to reduce the current when necessary; and one, sometimes two, Bunsen cells. The electrodes generally used are large copper plates, upon which the palms of the hands rest comfortably, or upon which the soles of the feet may be placed. We have also used jars of hot water for the contact, when, as with some instances of dementia praecox, the hands were congested and cold. Occasionally we have employed a plate of zinc for one electrode and a plate of carbon for the other (in which case no element was required, since the skin, sweat, and metal provided sufficient current).

II. THE PHYSICS AND PHYSIOLOGY OF THE "PSYCHOPHYSICAL GALVANIC REFLEX"

1046] So far as is known, it would seem that the sweat glands are the chief factor in the production of this electric phenomenon, on the one hand inducing under the influence of nervous stimulation a measurable current or, on the other hand, altering the conductivity of the current. Since water contact excludes changes induced by pressure on metal electrodes, and blanching of the fingers by the Esmarch bandage excludes changes in connection with the blood supply, both of these factors play but a small part in the deviations of the galvanometer. Change in resistance is brought about either by saturation of the epidermis with sweat, or by simple filling of the sweat-gland canals or perhaps also by intracellular stimulation; or all of these factors may be associated. The path for the centrifugal stimulation in the sweat-gland system would seem to lie in the sympathetic nervous system. These conclusions are based upon facts at present to hand and are by no means felt to be conclusive. On the contrary, there are features presented which are as yet quite inexplicable,[7] as, for instance, the gradual diminution of the current in long experiments to almost complete extinction, when our ordinary experience teaches that resistance should be much reduced and the passing current larger and stronger. This may possibly be due to gradual cooling of the skin in contact with the cold copper plates. This can be obviated by warm water contact or by resting the copper plates upon warm sand bags. Yet there is still an inviting field for investigation here.

1. *Fluctuations of the Galvanometer from Physical Causes*

1047] If the hands, placed upon the copper-plate electrodes, be pressed down firmly, there is a slowly-increasing deviation of the galvanometer, but only to a minor degree. If the area of contact be diminished by the raising of the fingers or by lifting of the palms, there is a sudden diminution in the amount of current, marked by sudden reduction of amplitude in the excursion of the light.

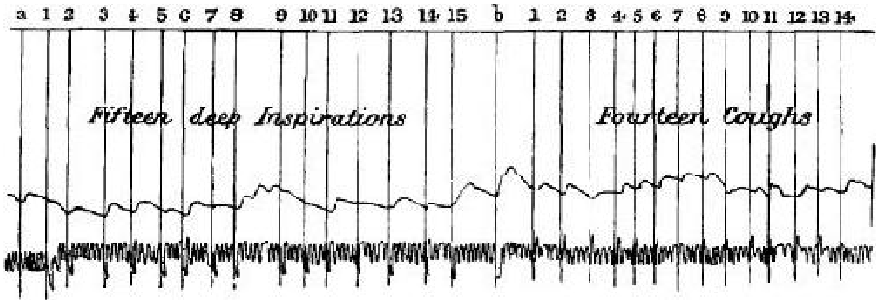

FIG. 1. Curve to show effects of deep inspirations and coughing upon the galvanometer

A deep inspiration alone, or a deep expiration, without alteration in the contact of the hands, increases the deflection of the galvanometer, while ordinary respiratory movements do not affect it. Coughing also causes a considerable rise in the galvanometric wave. We are inclined to think that this rise during inspiration, expiration, and coughing may also be of psychic, that is, emotional, origin. Certainly in the curve we observe exhaustion by repetition of the command to cough or breathe deeply, as in the case of other analogous stimuli. The deviations brought about by altered contact, by deep inspiration and expiration, and by coughing, are all readily recognized after some experience, and are readily differentiated from those depending wholly upon psychic influences. Warm hands naturally permit a larger current than cold hands. The level of the curve rises when the skin in contact grows warmer or moister, and descends with increase of coldness in the skin (see fig. 1).[8]

2. *Fluctuations of the Galvanometer from Psychic Causes in Normal Individuals*

1048] *Expectation*.—As soon as the galvanometric experiment begins, and the circuit through the subject is closed, there is a rather rapid rise with some fluctuation of a curve induced by expectant attention. Tarchanoff was much struck by this. Attention is, as Bleuler[9] has pointed out, nothing more than a special form of affectivity. Attention, interest, expectation, are all emotional expressions. The extent of this expectation curve rises in normal individuals, depending upon their varying degree of affectivity. Expectation is not only manifested at the beginning of an experiment in the galvanometer curve, but may also be observed throughout the experiment in connection with every stimulus, sensory or verbal. It is particularly strong in connection with the threat of pricking with the needle, or threat of letting fall a heavy weight. The influence of expectation on the curve becomes less with each repetition of the same series of stimuli, and seems to disappear wholly with indifferent stimuli; while, with the threat stimuli just referred to, which are more lively and actual, repetition may diminish the curve, or at times increase it if the test case is uncertain whether the threats in the repetition are to be a real prick of the needle or an actual fall of the weight. In beginning an experiment, we therefore wait until the first influence of the emotion of expectation has subsided.

1049] *Emotion*.—Excluding the affect of attention, we find that every stimulus accompanied by an emotion causes a rise in the electric curve directly proportional to the liveliness and actuality of the emotion aroused. The galvanometer is therefore a measurer of the amount of emotional tone, and becomes a new instrument of precision in psychological research.

1050] *Imagined emotion*.—The amount of deflection seems to stand in direct relation to the *actuality* of the emotion; but, as Tarchanoff pointed out, the presentation of an outlived emotion to the imagination deviates the galvanometer, such deviation depending naturally upon the facility of the subject in living over the old emotion in his imagination. The following experiment, tried upon one of the writers, is an illustration: The list of stimuli was placed before him, while the reader of the deviations called off at intervals Nos. 1—2—3—4—5—6, allowing time for concentration upon the idea, and for the rise and subsidence of the wave. Between the periods of concentration on the emotional images, the subject allowed his eyes to wander at random about the room, and his mind to run on indifferent objects that he saw.

An Experiment in the Deflection of the Galvanometer in Imagined Conditions

	Amount of deviation of galvanometer
(1) Expectant attention.	
(2) Imagined threat of prick with needle	4.3 cm.
(3) Imagined threat of fall of heavy weight	1.6 cm.
(4) Imagined grief	2.8 cm.
(5) Thought of an amusing story	1.8 cm.
(6) Thought of a painful illness in 1888	1.6 cm.

1051] *Series of stimuli used*.—A series of stimuli, sensory and verbal, strong and indifferent, intellectual and emotional, was arranged and tested upon numerous normal individuals, besides which word associations were used in connection with the galvanometer. In some of the experiments the subject was in an adjoining room, the electric connections and signals being easily adjusted for this purpose. The following is the series of stimuli:

(1) A loud whistle.
(2) Actual fall of a weight with a very loud noise.
(3) Multiply 4 by 5.
(4) Multiply 9 by 11.
(5) Multiply 8 by 12.
(6) Sudden call of subject by name.
(7) Where do you live?
(8) What is the capital of Switzerland?

(9) What is the capital of France?
(10) How old are you?
(11) Are you married?
(12) Were you engaged once before?
(13) Have you been long at your present employment?
(14) Threat of prick with needle after counting 1—2—3.
(15) Threat of allowing heavy weight to fall after counting 1—2—3
(16) What is your first name?
(17) What is the first name of your wife?
(18) Is she pretty?
(19) We have now finished.

1052] The verbal stimuli were varied to a slight degree with various individuals, to adapt them to different conditions and circumstances, but the general character of the stimuli was the same.

1053] These stimuli were ordinarily repeated three times for each individual, normal or pathological, and subsequently the series of word stimuli were given for the word associations, and these were also repeated once or twice. From seventy curves, fig. 2 (H., nurse, Series 3) is selected as a general illustration of the galvanometric curve. This man was emotional and in the third series here presented the curves are smaller and more rounded than in the first and second series. At the same time they serve to show the character of the emotional curve. Stimuli 3, 4, and 5, although they were but simple multiplication, induced an emotional curve, because H. was a nurse and was embarrassed at doing mental arithmetic before experimenters. Stimuli 8, 9, and 10 were practically exhausted in this third trial and show very little. Between 10 and 11 someone entered the room. The weight was let fall twice between 13 and 14 instead of at 2, and being unexpected produced a large and a smaller wave of alarm. The threatened prick of the needle at 14 and threat of fall of large leaden weight at 15 still produced large waves, and show how strongly actuality in an apprehension influences the curves. Again, at 18 the inquiry if his wife was pretty, she being far from it, induced a lively emotion and correspondingly high wave, for this question was here a surprise as well, not having been asked in the preceding series.

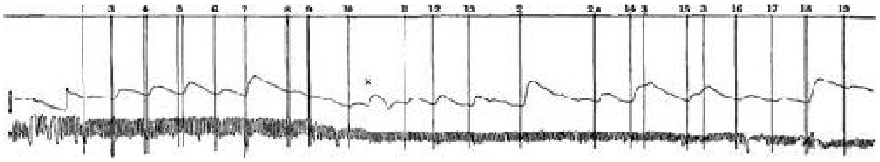

FIG. 2. Galvanometer and Pneumographic curves in a normal person (H., a nurse). The numbers at the top of each stimulus line correspond to the series of nineteen mixed stimuli printed in the text. 2 and 2a representing two falls of the weight occurred between 13 and 14 instead of between 1 and 2 in this curve, which was the second repetition of the series. Between 10 and 11 someone entered the laboratory

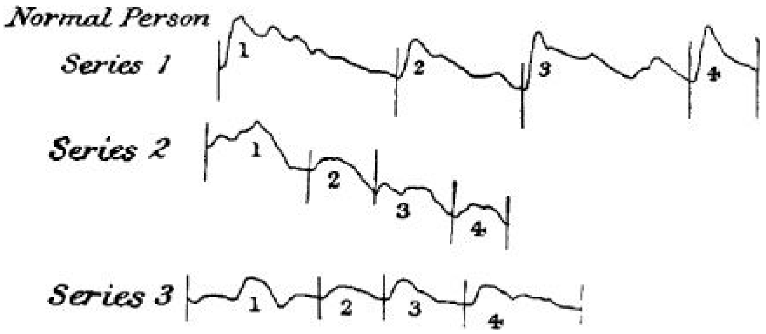

FIG. 3. Repetition of same stimulus questions in a normal person (H., a nurse) three successive times to show gradual exhaustion of emotional wave in the galvanometer curve. In 3rd series, question 1, someone entered the laboratory and caused an extra wave

1054] *Exhaustion of stimulus by repetition*.—When the first series of stimuli is recorded, the curves are usually characterized by abrupt ascent and descent with rather sharp summits. The curves diminish in size and the summits become more rounded in each repetition, showing a slower excitation and slower reaction of the emotion. This is well illustrated in fig. 3, where several curves induced by the same stimuli in the first, second, and third series in the same individual are reproduced. Wave No. 1 in Series 1 also exhibits in the descent the fluctuating character of an emotion which is slowly and waveringly passing off. This is even better shown in fig. 4, from Case G., who was asked questions calculated to produce a complex emotional state such as the galvanometer perfectly indicates. In quite a number of instances the heights of the waves of the three successive series were measured and the following two illustrations are selected as examples of the differences in height (in millimetres) of the curves of the stimuli in the three series. Waves were selected which had not been affected in any of the series by interruptions, change of contact, coughing, or deep inspirations.

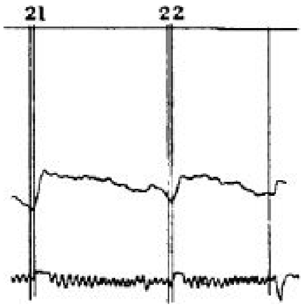

FIG. 4. Here G., a nurse, is asked about a quarrel with another nurse, H. The fluctuating galvanometer waves 21 and 22 represent the wavering emotions aroused

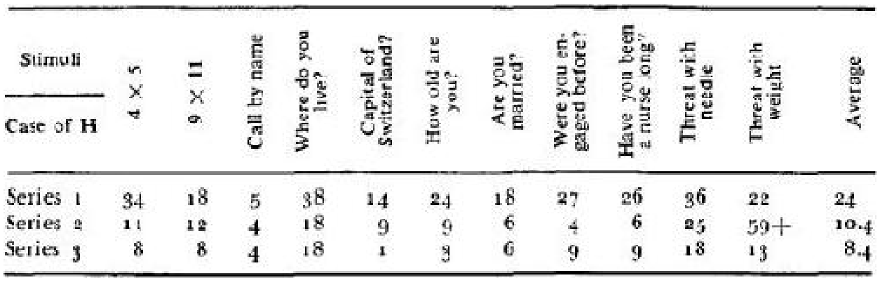
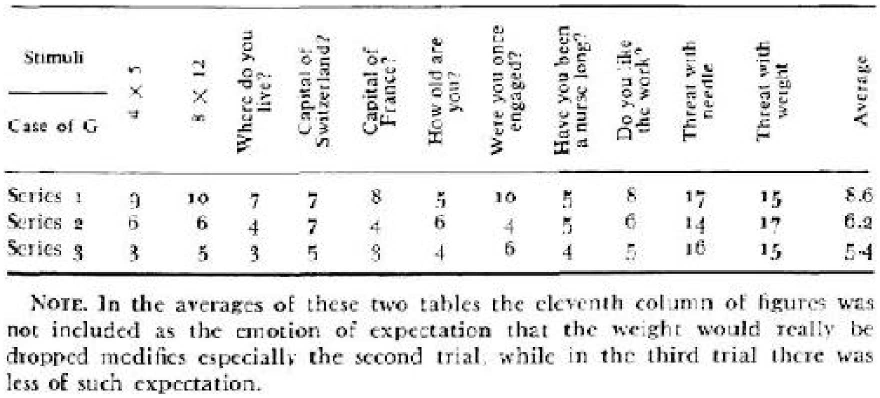
Table 1: Case of H. Diminishing Excursions of Galvanometer in Successive Stimulations



Stimuli Case of H	4 × 5	9 × 11	Call by name	Where do you live?	Capital of Switzerland?	How old are you?	Are you married?	Were you engaged before?	Have you been a nurse long?	Threat with needle	Threat with weight	Average
Series 1	34	18	5	38	14	24	18	27	26	36	22	24
Series 2	11	12	4	18	9	9	6	4	6	25	59+	10.4
Series 3	8	8	4	18	1	3	6	9	9	18	13	8.4

Table 2: Case of G. Diminishing Excursions of Galvanometer in Successive Stimulations



Stimuli Case of G	4 × 5	8 × 12	Where do you live?	Capital of Switzerland?	Capital of France?	How old are you?	Were you once engaged?	Have you been a nurse long?	Do you like the work?	Threat with needle	Threat with weight	Average
Series 1	9	10	7	7	8	5	10	5	8	17	15	8.6
Series 2	6	6	4	7	4	6	4	5	6	14	17	6.2
Series 3	3	5	3	5	3	4	6	4	5	16	15	5.4

Note. In the averages of these two tables the eleventh column of figures was not included as the emotion of expectation that the weight would really be dropped modifies especially the second trial, while in the third trial there was less of such expectation.

1055] In these tables the falling off of the height of the emotional curve is very well shown, and in both the livelier affects produced even in repetition by actual threats of the needle and weight are typical. In Series 2 of the first table the threat with the weight raised the curve to over fifty-nine because the subject thought that the weight would actually fall in this experiment, whereas before it was a threat only.

1056] *Latent time*.—It was noted by Tarchanoff that the galvanic wave began to rise from one to three seconds after a stimulus was given. We have verified this period of latent time in all normal conditions, but the latent time varies with different people and at different times. In the curves that we have thus far taken we could not well complicate the apparatus with a chronograph adjustment, and have estimated the space of latent time in a number of normal cases by measuring the distance of the curve from the moment of stimulation to the beginning of ascent of the emotional curve, taking the measurements in millimetres. The kymograph drum revolved slowly. The following results were obtained. Nurse B. with the series of mixed stimuli given above showed in the first series an average of 2.06 millimetres; the repetition of the second series averaged 2.55 millimetres; with Nurse G. and the same series of mixed stimuli in Series 1 the average was 1.85, in the second 1.76, and in the third or final series 2.32 millimetres. Dr. P. with the same series showed an average latent period in the first trial of 3.15, and in the repetition an average of 4.40. Dr. R. with the same series had an average period in the first trial of 4.05 millimetres, and in the second trial of 4.50 millimetres. In a series of word-associations Dr. R. showed at first an average period of 2.95 millimetres, and in the repetition immediately after the average was 4 millimetres. With word-associations Nurse H.

showed in the first series an average latent period of 2.26; in the repetition or second series the latent period was increased to 3.55, and with a third trial of the same words the latent period had become 4.14. These figures with regard to the latent period show therefore that with repetition there is an increase of the latent period of time simultaneously with the rounding off and diminishing amplitude of the curve, both corresponding with exhaustion of the power of the stimulus. We were unable to determine in this investigation that there was any marked difference in latent time in relation to the various forms of stimulation whether physical or psychic, and when psychic with or without answer to questions or words, though such differences will probably be discovered by further experiment directed to this end.[10]

1057] *Normal individual variations of galvanometer curve*.—We find considerable difference in the curves made by the galvanometer in normal persons. In some the waves are of rather small and even excursion, corresponding to the unemotional or phlegmatic nature of the subject. In other waves there is wide excursion, with fluctuating or bifurcated waves, rapid ascents and descents, expressing great emotional lability. These normal variations are illustrated in figs. 5 and 6.

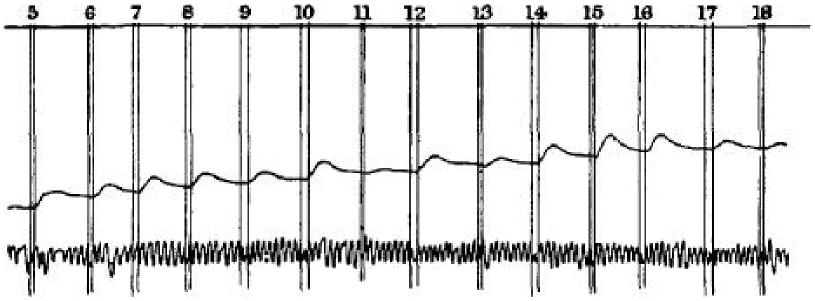


FIG. 5. Dr. R., normal curve with rather indifferent word-association stimuli. Unemotional type

III. The Pneumograph as an Indicator of Psychic Processes

1058] The relation of the respiratory innervation curve to psychic processes in both normal and pathological conditions has not yet been thoroughly investigated. Mosso was one of the earlier investigators (1879–1893) in the physiological application of the pneumograph and could reach no satisfactory conclusions from a study of the respiratory curve under sensory stimulation. Delabarre[11] states that respiration increases in frequency and depth with attention to sensory stimulation, and with mental processes increases in frequency and diminishes in depth. Lehmann[12] states that every pleasant impression increases the depth of breathing, and that strong unpleasant impressions are accompanied by several deep respiratory movements. Mentz[13] employed pleasant and unpleasant acoustic stimuli in a study of the pulse and breathing, and as regards respiration observed with strong stimulation first slowing and then shortening of the respiratory movements. He noted also a marked influence of attention on the results. Involuntary attention generally induced prolongation of breathing, while voluntary attention often caused abbreviation of the movements. Pursuing his studies further he investigated the action of pleasant and unpleasant stimuli and of the effects upon pulse and respiration. As regards the former, pleasant feelings lengthened the pulse curve and unpleasant ones shortened it, and he regards the respiratory curve as running a parallel course. With affects there was prolongation of the respiratory movements, and with increasing strength of the affects an increasing height or depth of the breathing curve. Zoneff and Meumann,[14] finding nothing sufficiently definite in literature in relation to the correspondence between respiration and circulation and psychic or emotional processes, have made an exhaustive research upon normal individuals, employing various stimuli, optic, acoustic, gustatory, cutaneous, and psychic (arithmetical problems and space conceptions), and studied at the same time the effects of voluntary attention and pleasant and unpleasant impressions upon the breathing and pulse. They found that as a rule attention produced acceleration of the breathing, especially at the end of the stimulation, and in addition to acceleration the breathing might become more shallow or be inhibited. This inhibition may appear as shallow and more rapid breathing, or there may be a partial or complete standstill of the respiration, which is greater in direct proportion to the degree of attention. Complete inhibition was found more often in attention to sensory than to intellectual stimulation. There were variations in the results in different individuals. There were fluctuations in the curves which they considered as being due to fluctuations in attention. In relation to pleasant and unpleasant stimuli, they concluded that all pleasant sensations cause shallowing and acceleration of the breathing, and all unpleasant sensations deepening and slowing of respiration, or, in other words, that the former diminish and the latter increase respiratory function. In experiments with diversion of the attention together with stimulation, they found that emotional effects upon breathing and pulse ceased. In experiments with concentration of attention on stimulus and sensation, attention strengthened the effects of both pleasant and unpleasant feelings upon the curves. While their work is the best that has yet appeared upon this subject, it must still be confessed that experiments of this nature carried out upon the trained assistants or students connected with the laboratory are more or less artificial, and this, together with the extremely simple character of the stimulation, would make their criteria for the more complex emotional phenomena with which we have to deal only relatively valuable.

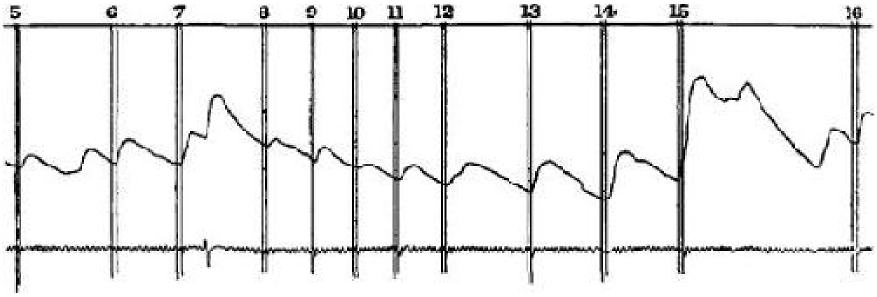

FIG. 6. H., an attendant, normal curves, very labile emotions. The numbers here correspond to the series of mixed stimuli; 15 is threat of weight

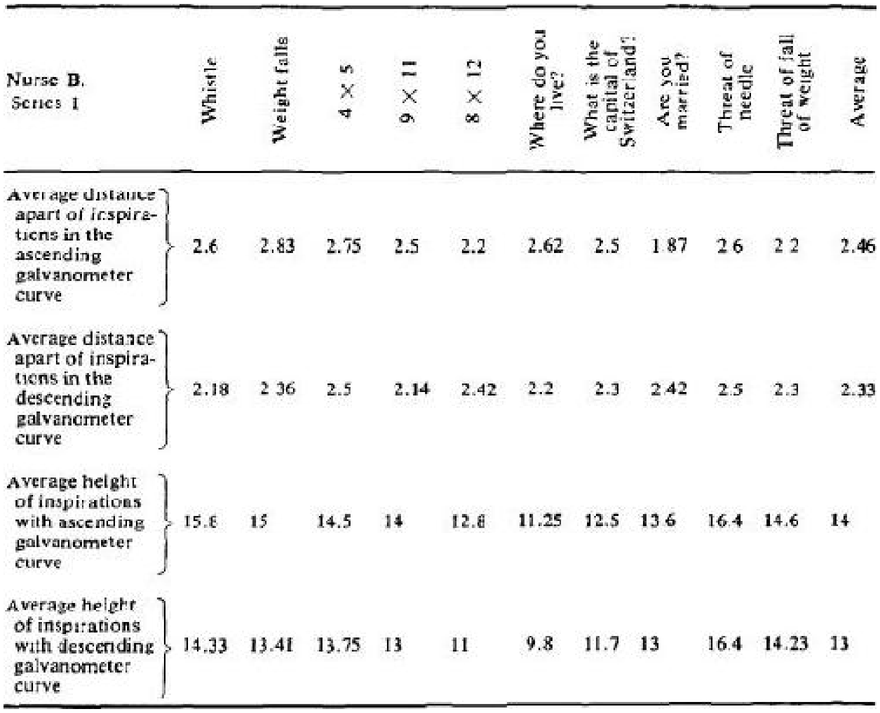
1059] Martius and Minnemann[15] in a thoroughly iconoclastic and yet excellent work point out many fallacies in the studies of Lehmann, Menz, and Zoneff and Meumann, artifacts of a mechanical nature, and wrong conclusions as to the relations between affects and pulse and breathing curves. They themselves find the normal respiratory curve inconstant, subject to variations due to age, temperament, perseveration of affect, reactions from the affect, embarrassment from the experiment, undue interest in the procedure, etc., and their chief conclusion is that the main changes in breathing in emotional conditions consist of quickened or lengthened tempo, with diminished height in either case.

1060] Believing that a study of the inspiratory curve would throw the most light upon the relation of respiratory innervation to psychic processes, we set before ourselves several problems for consideration, viz., the character of the usual respiratory curve, the character of the curve in stimulation without verbal reaction, the influence of verbal reaction with indifferent stimuli upon the curve, whether distinct emotional complexes affected uniformly the pneumographic curve, whether there were marked disturbances of the respiratory without corresponding changes in the galvanometric curve, and, finally, what influence attention has on both galvanometer and pneumograph. We have not been able as yet to reach satisfactory conclusions on all of these points, for the material already available is more than we have yet had opportunity to investigate thoroughly; but so far as they go the results obtained are of interest. The figures in the table for one of the cases given here show a regular, though not constant, relation between the galvanometric and the pneumographic curves.

1061] To obtain these relations it is necessary to select an experiment in which the galvanometric curve has not been influenced greatly by the several sources of error, and the simultaneous pneumographic curve has not been modified too much by verbal reaction, coughing, etc. Taking the typical curves of several such series, measurements were made to determine the relative number of inspirations synchronous with the ascending galvanometer curve, and also with the descending galvanometer curve. The amplitude of each inspiration was also measured and averaged for the same purpose, and the measurements are recorded in millimetres. It will be seen that the ascending portion of the galvanometer curve, which is the result of an emotional stimulus, is accompanied by fewer inspirations as well as by deeper ones. While this seemed to be a general rule in this instance, we find variations in different individuals with the same mixed series of stimuli, and in some cases the reverse. The stimuli in the tables were unpleasant rather than pleasant to the subject. But the determination of the quality of the emotional tone in any such experiment is very difficult. The forced and artificial situation of the subject in itself induces unpleasant feelings, and any pleasant stimulus must therefore simply bring about a certain relief or relaxation in a situation of unpleasant tension. The nervous tension during an experiment must naturally influence the breathing, and a pleasant stimulus is apt to produce only a temporary lessening of such tension. This is a criticism we would make of the Zoneff and Meumann experiments, and of experiments with the pneumograph in general. It is altogether probable that there are more inexplicable influences at work in relation to the pneumographic curve than we are at present able to comprehend. There are many respiratory fluctuations which have nothing to do with the emotions, but are the result of physical or intellectual processes, with the enforced quiet of body of the subject, with the disposition to speak, with tendencies to cough or to swallow, etc. Furthermore, there will be a difference in the curve if the stimulus occurs during an inspiration or an expiration, and there are individual variations dependent upon temperament or upon lability of the emotions.

Measurements to Show the Relation in Frequency and Amplitude of Inspirations to Ascending and Descending Portions of the Galvanometer Wave



Nurse B. Series I	Whistle	Weight falls	4 × 5	9 × 11	8 × 12	Where do you live?	What is the capital of Switzerland?	Are you married?	Threat of needle	Threat of fall of weight	Average
Average distance apart of inspirations in the ascending galvanometer curve	2.6	2.83	2.75	2.5	2.2	2.62	2.5	1.87	2.6	2.2	2.46
Average distance apart of inspirations in the descending galvanometer curve	2.18	2.36	2.5	2.14	2.42	2.2	2.3	2.42	2.5	2.3	2.33
Average height of inspirations with ascending galvanometer curve	15.6	15	14.5	14	12.8	11.25	12.5	13.6	16.4	14.6	14
Average height of inspirations with descending galvanometer curve	14.33	13.41	13.75	13	11	9.8	11.7	13	16.4	14.23	13

1062] We have, therefore, not been greatly impressed with the value of a possible relation between the galvanometric and pneumographic curves since this is not constant, and the more comparative study we have given to the two synchronous curves, the more we have been impressed with a surprising divergence between the influences at work upon them. We have studied hundreds of waves in every conceivable manner. For instance, we have taken series of galvanometric curves and carefully measured the length of each inspiration, and the intervals between inspirations, as related to the point of stimulus, to the latent space before the ascent of the galvanometer wave, to the ascending curve, to the crest, to the descending curve, and to the space next to the point of stimulus, without developing any regular and constant relationship of correspondence, though we think this may ultimately be shown to exist in some degree. On the contrary, we have found thus far that the influences at work upon the two curves reveal an astonishing regularity of difference. When the emotions are very labile, and show the most marked excursions in the galvanometer curve, the respiratory curve is often regular and even (fig. 7). On the other hand, in instances both normal and pathological, where the galvanometer curve is marked by little fluctuation, or even by none, as in some cases of catatonia, there will often be most decided variations in the pneumographic curve. We often note a change in character in the pneumographic curve, not so much with each separate stimulus, but during the whole course of a series of stimuli as if expectant attention and nervous tension diminished the inspirations during the early part of the series, and as if there were a relaxation during the later half with longer inspirations (fig. 8). There does not seem to be the intimate and deep relationship between the respiratory function and the unconscious emotions that exists between the sweat glandular system and these emotions. It is a matter of everyday experience that the respiration is influenced by our conscious emotions, especially when they are strong, as instanced in such expressions as “bated breath,” “breathless with astonishment,” etc. Such inhibitions of breathing are noticeable in many pneumographic curves, particularly in association with expectation and tension. But perhaps the emotions of the unconscious, roused up by questions or words that strike into the buried complexes of the soul, reveal themselves in the galvanometer curve, while the pneumographic curve is comparatively unaffected. Respiration is an instrument of consciousness. You can control it voluntarily while you cannot control the galvanometer curve. The respiratory innervation is closely associated with speech innervation, anatomically and functionally, and the physical connection in the brain is, perhaps, one of the closest and earliest. Let us take these remarkable curves of a case of acute catatonia (figs. 9A and 9B), which may be regarded as a psychological experiment in diverting both attention and ordinary emotion. Attention and all other emotions being practically diverted by the pathological process, the galvanometer curve is slight (indeed, in the *second* repetition it was a straight line), but the sudden call of the patient by name produced the extraordinary fluctuations in the respiratory curve, though nothing was apparent in his outward demeanour to show that he was conscious in any degree of the stimulus. He may have been conscious of the call, but we had no means of determining this. In the repetition the same fluctuations occurred, proving that they were not fortuitous. The only reasonable explanation of this phenomenon, in our opinion, is that the call of the name developed a disposition to speak, stimulated the hearing centre, and the closely-associated speech centre, the motor innervation from which acted upon the respiratory muscles. Ordinarily a sudden call by name, which is one of the strongest and deepest of stimuli, produces an answer. In this instance the call by name was a stimulus that acted as in a simple reflex process, and led to motor manifestations in the respiratory muscles connected with the motor speech centre, analogous to the contraction of the eyelids in response to a sudden flash of light. Fig. 10 is another instance of almost like character.

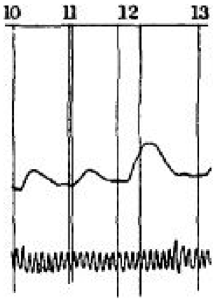


FIG. 7. Dr. P., normal good-sized galvanometer curves with fairly regular respiratory curve

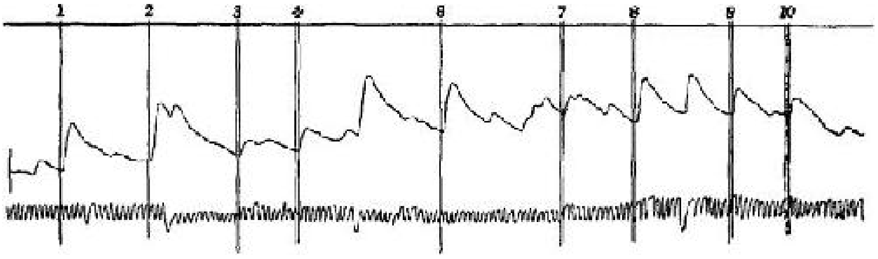

FIG. 8. Dr. S., a patient with paranoid dementia (Case No. 3). Extraordinarily labile emotions expressed in galvanometer curve. Considerable tension in pneumographic curve from stimulus 2 (fall of weight) on, with relaxation and deeper breathing beyond stimulus 7. An example of perseveration of tension for a long period in the pneumographic curve

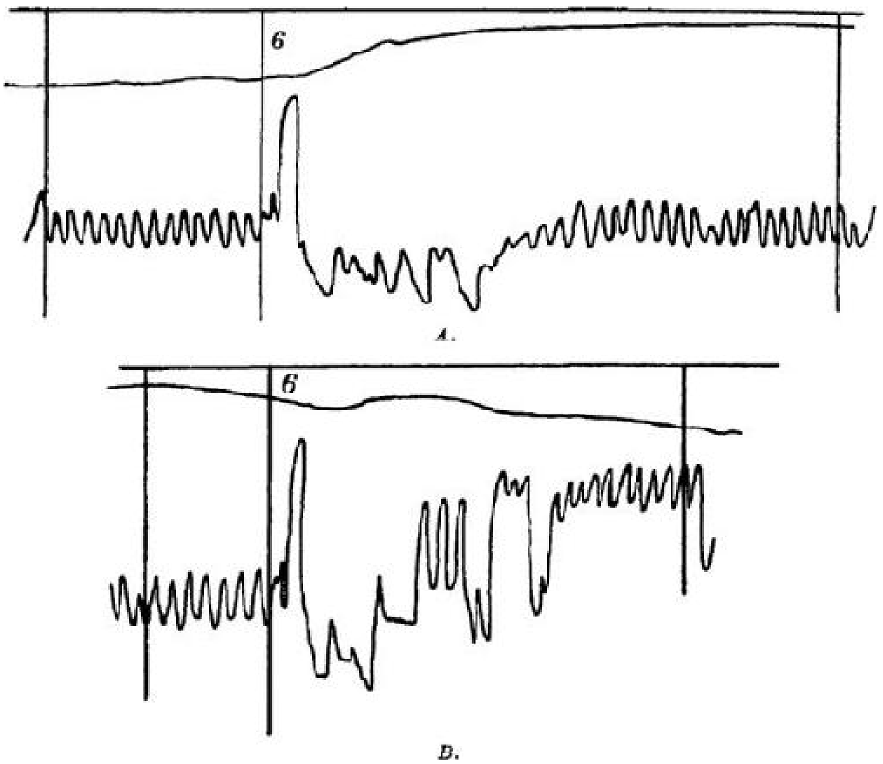

FIG. 9. J., acute catatonic stupor (Case No. 10). *A* is a wave selected from the series in which 6 is sudden call by name. The galvanometer curve is slight, but the change in the pneumographic curve is notable. *B* is the same stimulus in the repetition of the series. (Fig. 9 is reproduced actual size of the tracing)

1063] While inconstancy of emotional variations in the respiratory curve and in correspondence with the galvanometer curve has been the rule in our findings thus far, we have learned that inhibitions, when they occur as an expression of expectant attention or of other emotions, are almost always shown in the expiratory curve and not in the inspiratory, which would accord with our idea that active, intellectual, emotional or conscious innervation is chiefly associated with inspiration, whereas expiration is rather a physical process or relaxation, prone to be inhibited, but not otherwise affected by the active respiratory nerves.

1064] In reiterating our opinion that the galvanometer curve is probably more intimately connected than the pneumographic curve with the subconscious emotional complexes, we would add that there is a greater tendency also to persistence in the pneumographic curve when emotion is expressed in it, for the galvanometer curve subsides rather quickly with the fall of the emotion, while the pneumographic curve may show traces of conscious reminiscence of the emotional stimulus for a much longer time. The galvanometer is rather an index or measure of acute feeling-tone.

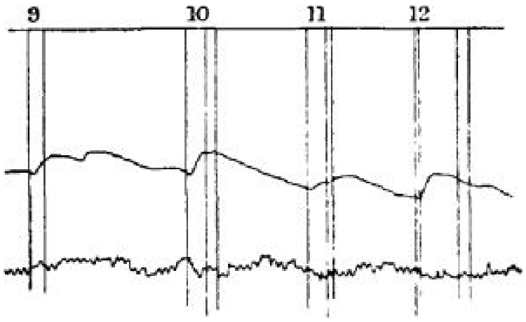

FIG. 10. Miss S., paranoid dementia (Case No. 2), stimuli 9, 10, 11, 12, correspond to numbers in the mixed series printed in the text. The noteworthy changes in the respiratory curve are due to her constant “disposition to speak.” She did not speak except in answer to the questions given, but she apparently whispered most of the time between audible answers. Sometimes there was slight movement of the lips, when real whispering was not apparent

1065] Thus far, for the purposes of this study of the curves under normal conditions, we had made some forty series of curves in eight normal individuals, educated and uneducated. After this we made some thirty series of curves in eleven cases of dementia praecox of different types, viz.: Dementia paranoides three, hebephrenia two, and catatonia six cases (three chronic and three acute), and to these tests we will now turn our attention.

IV. The Galvanometric and Pneumographic Curves in Dementia Praecox

1066] Before recording the results of our experiments in dementia praecox it is necessary to say something of the psychology of the disorder. The chief characteristic in the mental condition of these patients is a peculiar disturbance of the emotions. In chronic conditions we have, as Kraepelin has clearly shown, an “emotional atrophy.” In acute conditions there is a species of “inco-ordination” or “ataxia” between affectivity and concepts, well demonstrated by Stransky.[16] The emotional disturbance has also been called “inadequate emotional tone.” But these phrases represent rather the superficial impression that these patients make upon the physician. As soon as one examines the phenomena analytically and critically, the difficulty of attaining to a common point of view as regards all the morbid emotional symptoms is found to be extraordinary. We see at once that in most cases of dementia praecox none of the emotions is either changed or destroyed. We find, indeed, on closer analysis that many normal feelings are present. Cases with complete loss of emotion are exceptional. Elementary affects, such as fright, anxiety, pleasure, anger, embarrassment, shame, etc., are usually preserved. There is even at times an increased affectivity, or real nervous sensitiveness, present. Furthermore, in cases where one would expect more or less diminution of affectivity from their previous conduct and life, the elementary feelings are still maintained. The disorder is then shown in what Janet calls the *fonction du réel*[17] or the psychological adaptation to the environment. It is hardly to be expected that we should find characteristic disturbances in such patients by our experimental method (psychogalvanic), since they would lie in quantitative differences between the various feeling-tones. Even if there were qualitative changes, these would be too small for recognition.

1067] One of the chief factors in psychological adaptation to the environment is attention, which renders possible all the associations necessary to normal existence. In dementia praecox, especially the catatonic form, there are marked disorders of attention, which are shown by lack of power of voluntary concentration; or, otherwise expressed, objects do not excite in the diseased brain the affective reaction which alone permits an adequate selection of intellectual associations. This defective reaction to stimuli in the environment is the chief feature of dementia praecox. But this disorder is neither simple nor elementary; on the contrary, it is very complicated. What is its origin? There is in the psychology of dementia praecox still another characteristic that throws light upon the problem. By means of word associations and subsequent analysis we find in these cases, among other abnormal manifestations, certain thought-complexes associated with strong emotional tone, one or several of which are fundamental complexes for the individual and embody as a rule the emotions or experiences that immediately preceded the development of the mental disorder. In suitable cases it is possible without much trouble to discover that the symptoms (delusions, hallucinations, insane ideas) stand in close relation to these psychological antecedents. They in fact, as Freud has shown, determine the symptoms. Freud applied his method particularly to hysteria, in which he found conscious or unconscious constellations, with strong affective tone, that may dominate the individual for years, or even the whole life through, by the force they exert upon associations. Such a morbid complex plays the part of an independent being, or soul within a soul, comparable to the ambitious vassal who by intrigue finally grew mightier than the king. This complex acts in a particular way upon the psyche. Janet has described it in an excellent manner in his book.[18] The complex robs the ego of light and nourishment, just as a cancer robs the body of its vitality. The sequelae of the complex are briefly as follows: Diminution of the entire psychic energy, weakening of the will, loss of objective interest and of power of concentration and of self-control, and the rise of morbid hysterical symptoms. These results can also manifest themselves in associations, so that in hysteria we find clear manifestations of emotional constellations among their associations. But this is not the only analogy between dementia praecox and hysteria. There are numerous others, which we cannot describe here in detail. One may, however, call attention to the large number of undoubted catatonic processes which were formerly called “degenerative hysterical psychoses.” There are many cases, too, of dementia praecox which for years cannot be distinguished from hysteria. We call attention to the similarity of the two disorders here in order to show that our hypothesis of the relation between “psychological adaptation to environment” and an emotional complex is an established fact in the matter of hysteria. If we find in dementia praecox similar conditions, we are justified in assuming that here, too, the general disturbances of mind may have a close causal relationship with an underlying complex. The complex is naturally not the only cause of dementia praecox, as little as it is of hysteria. Disposition is also a chief agency, and it is possible that in the disposition to dementia praecox affectivity brings about certain irreparable organic disturbances, as for instance metabolic toxins.

1068] The difference between dementia praecox and hysteria lies in certain irreparable sequelae and the more marked psychic disturbances in the former disorder. Profound general disturbances (delirium, severe emotional crises, etc.), exceptional in hysteria, are usual in dementia praecox. Hysteria is a caricature of the normal, and therefore shows distinct reactions to the stimuli of the environment. In dementia praecox, on the other hand, there is always defective reaction to external stimuli. There are characteristic differences in relation to the complex. In hysteria the complex may with very little trouble be revealed by analysis, and with a good prospect of therapeutic advantage in the procedure. But with dementia praecox there is no possibility of its being thus influenced. Even if, as is sometimes possible, the complex may be forced to reproduction, there is as a rule no therapeutic result. In dementia praecox the complex is more independent and more strongly detached, and the patient more profoundly injured by the complex than is the case in hysteria. For this reason the skilled physician is able to affect by suggestion acute hysterical states, which are nothing but irradiations from an excited complex, while he fails in dementia praecox where the inner psychic excitement is so much stronger than the stimuli from the environment. This is also the reason why patients in the early stages of dementia possess neither power of critical correction nor insight, which never fail in hysteria even in the severest forms.[19]

1069] Convalescence in hysteria is characterized by gradual weakening of the complex till it vanishes entirely. The same is true in the remissions of dementia praecox, though here there is always some vestige of irreparable injury, which, even if unimportant, may still be revealed by study of the associations.

1070] It is often astonishing how even the severest symptoms of dementia praecox may suddenly vanish. This is readily understood from our assumption that the acute conditions of both hysteria and dementia praecox are the results of irradiations from the complex, which for the time conceal the normal functions that are still present. For example, some strong emotion may throw a hysterical person into a condition of apathy or delirium, which may disappear the next moment through the action of some psychological stimulus. In like manner stuporous conditions may come and go quite suddenly in dementia praecox. While such patients are under the spell of the excited complex, they are for the time completely cut off from the outside world, and neither perceive external stimuli nor react to them. When the excitement of the complex has subsided, the power of reaction to the environment gradually returns, first for elementary and later for more complicated psychological stimulation.

1071] Since, according to our hypothesis, dementia praecox can be localized in some dominating psychological complex, it is to be expected that all elementary emotional reactions will be fully preserved, so long as the patient is not completely in the control of the complex. We may, therefore, expect to find in all patients with dementia praecox who show psychological adaptation in elementary matters (eating, drinking, sleeping, dressing, speaking, mechanical occupation, etc.) the presence of some adequate emotional tone. But in all cases where such psychological adaptation fails, external stimuli will produce no reaction in the disordered brain, and even elementary emotional phenomena will fail to become manifest, because the entire psychic activity is bound up with the morbid complex. That this is an actual fact is shown in the results of our experiments.

1072] The following is a brief *résumé* in each case of the features that are of interest for us here:

(1) H., male, aged 43, teacher of languages. First insane ten years ago. Well educated and intelligent. Entered an asylum for a time in 1896. Passed through a light period of catatonia with refusal of food, bizarre demeanour, and auditory hallucinations. Later constant persecutory ideas. In August 1906, he murdered one of his supposed persecutors, and since then has been in this asylum. Very precise and correct in his dress and conduct, industrious, independent, but extremely suspicious. Hallucinations not discoverable. Diagnosis—*Dementia paranoides*.

(2) Miss S., aged 61, dressmaker. Became insane about 1885. Innumerable bizarre delusions, delusions of grandeur, hallucinations of all the senses, neologisms, motor and language stereotypy. Conduct orderly, neat, industrious, but rather querulous. Is on parole and shows considerable independent activity. Diagnosis—*Dementia paranoides.*[20]

(3) Dr. S., male, aged 35, chemist. Became insane about 1897. Very intelligent and reads numerous scientific books. Has many wants and makes many complaints. Extremely careful in dress, and is extraordinarily neat. Numerous grandiose ideas and hallucinations. No catatonic symptoms. Diagnosis—*Dementia paranoides*.

(4) Mrs. H. O., aged 44, farmer’s wife. Became insane in 1904 with an attack of hebephrenic depression. Since the end of 1906, in a second attack of similar character. Speaks only in whispers. Somewhat inhibited, anxious, and hears very unpleasant voices. Works industriously and spontaneously. Neat in dress and in care of her room. Diagnosis—*Hebephrenic depression*.

(5) Mrs. E. S., aged 43, merchant’s wife. Became insane in 1901. Occasionally light maniacal excitement, never confusion at first, but rapid dementia. Now greatly demented, inactive, and vexes other patients. Unemotional, indifferent, and untidy in

dress. Without interest in her husband or surroundings. Chatters a great deal, but quite superficially, and it is impossible in any way to arouse in her any of the deeper emotions. Diagnosis—*Hebephrenia*.

(6) A. V. D., male, aged 39. Entered the asylum in 1897. From the beginning quiet, unemotional, somewhat timid and anxious. Speech fragmentary and indistinct, and most of the time talks to himself. Makes meaningless gestures with the hands. Has to be cared for by the attendant in all matters. Cannot work. Shows neither homesickness nor desire for freedom. Automatism on command and at times catalepsy. Diagnosis—*Chronic catatonic stupor*.

(7) Sp., male, aged 62, factory worker. Became insane in 1865. In the early stages several attacks of catatonic excitement. Later chronic stupor with occasional raptus. In one attack of raptus tore out one of his testicles with his hand. At another time suddenly kissed the attendant. During a severe physical illness at one time he suddenly became quite clear and approachable. Speaks only spontaneously and at long intervals. Works only mechanically when he is led to it. Stereotyped gestures. Diagnosis—*Chronic catatonic stupor*.

(8) F., male, aged 50. Became insane in 1881. At first, for a long period, depressed inhibition. Later, mutism, with occasional outbursts of abusive language on account of voices and numerous hallucinations. At present constant hallucination, though he is quiet, speaking only when addressed, and then in a low, fragmentary manner. Occasionally outbreaks of abuse because of the voices. Works mechanically, and is stupid and docile. Diagnosis—*Chronic catatonia*.

(9) J. S., male, aged 21. Became insane in 1902. Stupid, stubborn, negativistic, speaks spontaneously not at all or very seldom, quite apathetic and without affectivity, sits the whole day in one place, wholly disorderly in dress. Once in a while demands release with some irritation. Diagnosis—*Mild catatonic stupor*.

(10) J., male, aged 21, student of philosophy and very intelligent. Became insane about 1901, when he had a short attack. The second attack came in December last (1906). At times excited, wholly confused, and strikes about him. Incessant hallucinations. Wholly wrapped up in his inner mental processes. In occasional intervals of some lucidity, the patient states quite spontaneously that he has no feeling at all, that he cannot be either glad or unhappy, that everything to him seems wholly indifferent. Diagnosis—*Acute catatonic stupor with raptus*.

(11) M., male, aged 26, merchant. Became insane in 1902. At first maniacal excitement. Later dull apathy and occasional exhibition. Then gradually increasing stupor, with complete detachment. Now mutacismus, and tears out his beard, but at other times rigid and cataleptic. Diagnosis—*Acute catatonic stupor*.

1073] The galvanometer curves in many of the tests with dementia praecox were extraordinary. As in normal individuals we found, where there was reaction at all, a gradual exhaustion of the power of the stimulus in repetitions of the same series, so that the waves became smaller in the second, and still smaller and more rounded in the third series. In some cases, where the waves were small in the first series, they disappeared altogether in the third. In fig. 8 we have a good example of a very labile galvanometer curve from a case of dementia paranoides, in which we have abrupt and high ascents, at times with large bifurcations. This was the second series of this patient, and the curves are smaller than in the first. They may be compared with the labile normal curve of fig. 6, which was the first series; and also with fig. 10, another case of paranoid dementia, but in which the galvanometer wave is rather unemotional, while the pneumographic curve shows in this instance such marked changes owing to the disposition to whisper. The type of galvanometer curve, shown in fig. 8, is also characteristic of curves we have taken in hysteria.

1074] In the hebephrenic type there is nothing especially noteworthy in the curve, either in respect of great lability or smallness of wave. In the catatonic forms of dementia praecox, especially in the acute forms, however, we observed extraordinary variations from the normal in the character of the curve. Not only is the latent time longer, but the waves are almost always of gradual ascent, and very small if present at all. Figs, 9A and 9B, from a case of acute catatonic stupor, present illustrations of curves brought about by the sudden calling of the name. The galvanometer curve is exceedingly slight, but the pneumographic curve shows the singular changes previously mentioned. In fig. 11 (p. 522) we show three galvanometer curves. The upper one is from a normal person, with the series printed in the text. The middle one is that of a case of chronic catatonic stupor (Sp.), which is characterized by almost no reaction to any stimuli until 14 is reached, when the threat of pricking with a needle (and the actual prick where the line crosses the up wave) produced a great rise in the curve. A slighter rise occurred at 15, the threat to let the weight fall. This is an example of reaction to an elementary emotion in a chronic case where some emotional tone is still present. The lowest line in fig. 11 represents the galvanometer curve of an acute case of catatonic stupor (J.), and here it is seen that the line is perfectly straight, that not one of the mixed series of stimuli printed in the text had the slightest effect; whistle, dropping of the weight with a loud noise, sudden loud call by name, actual hard pricks with the needle—nothing brought out a response in the galvanometer. The pneumograph could not be applied in this case. Our experience with the six cases of catatonia is that such curves are characteristic for the type, and bear out our idea of the psychology of the disease as recorded above.

1075] Another feature of importance in these cases is the matter of latent time. It will be remembered that latent time, before the rise of the galvanometer wave, was estimated by us to vary in normal persons between two and five seconds. In fact, the norm is three seconds for first series, and 3.77 seconds for subsequent series. In the following tables, one relating to latent space on the kymograph, and the other to latent time, only seven of the eleven cases of dementia praecox appear, for in the others the waves were so slightly marked or so uncertain that the facts could not be satisfactorily determined. One of these patients (Dr. S.) was tested with both the mixed series and a series of word associations.

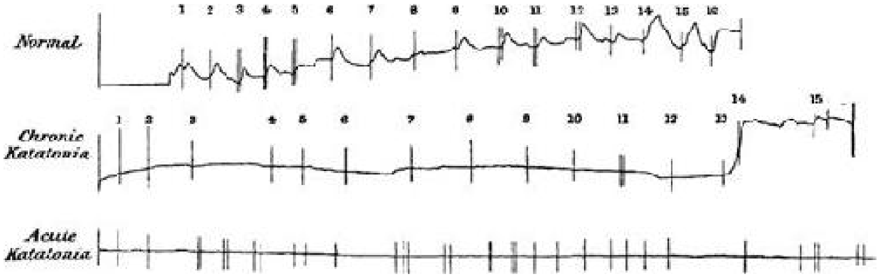

FIG. 11. Three galvanometer curves for contrast. The first curve is a normal one, with series of mixed stimuli (Miss B., a Canadian). The second curve is that of Sp. (Case No. 7), one of chronic catatonic stupor. Note presence of elementary emotion at stimulus 15. The third curve is that of J. (Case No. 10, acute catatonic stupor). No change whatever in the galvanometer curve to any of the mixed stimuli

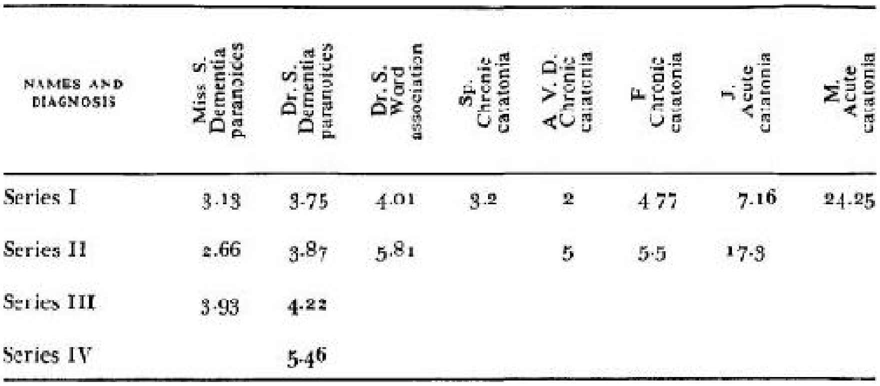
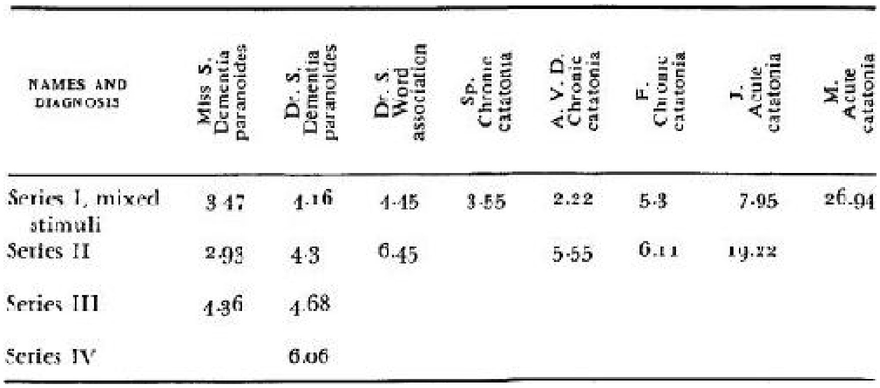
Latent Time in Millimetres of Distance from Stimulus to Beginning of Ascent of Galvanometer Emotional Wave in Cases of Insanity



NAMES AND DIAGNOSIS	Miss S. Dementia paranoides	Dr. S. Dementia paranoides	Dr. S. Word association	Sp. Chronic catatonia	A. V. D. Chronic catatonia	F. Chronic catatonia	J. Acute catatonia	M. Acute catatonia
Series I	3.13	3.75	4.01	3.2	2	4.77	7.16	24.25
Series II	2.66	3.87	5.81		5	5.5	17.3	
Series III	3.93	4.22						
Series IV		5.46						

Latent Time in the Same Cases of Insanity as Above Estimated in Seconds



NAMES AND DIAGNOSIS	Miss S. Dementia paranoides	Dr. S. Dementia paranoides	Dr. S. Word association	Sp. Chronic catatonia	A. V. D. Chronic catatonia	F. Chronic catatonia	J. Acute catatonia	M. Acute catatonia
Series I, mixed stimuli	3.47	4.16	4.45	3.55	2.22	5.3	7.95	26.94
Series II	2.93	4.3	6.45		5.55	6.11	19.22	
Series III	4.36	4.68						
Series IV		6.06						

1076] In the first case, a woman with dementia paranoides, the latent time is within normal limits. In the second case, also dementia paranoides, Dr. S., the normal was overstepped only in the fourth round of the same mixed series, but, with the same patient using word association, the latent time was excessive (6.45) in the first repetition of the same words. In the third case (Sp.), a case of chronic catatonia, the first series showed a latent time of 3.55 seconds, but there were no waves whatever in the repetitions. The four succeeding patients, all cases of catatonia, show increase of latent time, and the two acute cases of catatonia present an astonishing interval of space and time between the stimulus and the galvanometer wave.

1077] The following table will better show the differences in latent time between the normal and cases of dementia praecox, especially in the averages given at the end of the table.

Comparative Table Showing Latent Time in Galvanometer Curve of Normal Cases and of Dementia Praecox

										Average	Average of distribution
Normal	Series I	2.28	2.05	3.5	4.5	3.27	2.51			3.01	.73
	Series II and III	2.83	1.95	4.88	5	4.44	3.94	2.57	4.6	3.77	.99
Dementia Praecox	Series I	3.47	4.16	4.45	3.55	2.22	5.3	7.95	26.94	7.25	5.09
	Series II and III	2.93	4.3	6.45	5.55	6.11	19.22	4.36	4.68	6.70	3.13

1078] The average of distribution is obtained by subtracting the ordinary average from the larger numbers in the series, or the smaller numbers from the average. The sum of these differences is divided by the number of items, which gives what is called the average of distribution or the average of differences—a useful method of showing wide fluctuations in pathological conditions.

V. ASSOCIATION EXPERIMENTS

1079] Galton, Wundt, Kraepelin, Aschaffenburg, Sommer, and others have introduced into psychology a very simple experiment in which a word is called out to the subject, who must respond as quickly as possible with the first word that occurs to him. The reaction-time between the stimulus-word and the response can be measured with a one-fifth-second stop-watch. It was originally expected that this method would reveal certain intellectual differences in various individuals. But from the results of investigations carried out in the Psychiatric Clinic at Zurich, it has been found that it is not intellectual factors but the emotions that play the chief part in determining these associations. Two persons, of the same social class, one intelligent, the other unintelligent, even with differences in the character of their intellectual development, may still produce similar associations, because language itself has many general word connections which are familiar to all sorts of individuals belonging to the same circle of society.

1080] There are certain well-marked differences between the word associations of educated and uneducated persons. For instance, the uneducated prefer inner connections with deeper meaning, while the educated very often select simply superficial and linguistic associations. As has been ascertained at the Zurich Clinic, this difference depends upon the fact that the uneducated fix their attention more closely than the educated upon the actual meaning of the stimulus word. But attention, as has been shown by Bleuler, is nothing more than an emotional process. All affective processes are more or less clearly connected with physical manifestations, which are also to be observed in conjunction with attention. It is therefore to be expected that the attention roused by every association should have an influence upon the galvanometer curve, though this is but one of the affective factors represented in an association experiment.

1081] We observe, as a rule, considerable variation in reaction-time, even with quick and practised subjects. One is inclined to explain such irregularities, which are apparently accidental, by supposing that the stimulus-word is unusual and difficult or that the attention is momentarily relaxed for some reason or another. Such may at times be the case, but these reasons are not sufficient to explain the frequent repetition and long duration of certain reaction-times. There must be some constant and regular rule to account for them. This disturbing factor has been found at the Zurich Clinic to be in most cases some characteristic thought-complex of intrinsic importance for the personality of the subject. The following series will illustrate our meaning:

Stimulus-word	*Reaction-word*	*Reaction-time*
head	hair	1.4
green	meadow	1.6
water	*deep*	*5*
stick	knife	1.6
long	table	1.2
ship	*sink*	*3.4*
ask	answer	1.6
wool	knit	1.6
spiteful	friendly	1.4
lake	*water*	*4*
sick	well	1.8
ink	black	1.2
swim	*can swim*	*3.8*

1082] The four italicized numbers are abnormally long reaction-times. The stimulus-words are quite ordinary, are not difficult, and are such as commonly carry numerous current connections. By questioning the patient, we learn that recently, when greatly depressed, he had determined to commit suicide by drowning. *Water, lake, ship, swim* were words that excited this complex. The complex brought about lengthening of the reaction-time. This phenomenon is quite usual, and is to be observed constantly and everywhere in association studies. Lengthened reaction-time may therefore be regarded as a complex indicator, and be employed for the selection from a series of associations of such as have a personal significance to the individual. It is self-evident that associations of this kind are apt to be accompanied by lively emotional tone. The explanation would be simple if the subject were always conscious of the complex which had been excited. But it is extraordinarily common for the subject to be unconscious of the complex disturbed by the stimulus-word, and to be unable to answer questions relating to it. It is then necessary to employ the psychoanalytic method, which Freud uses for the investigation of dreams and hysteria. It would carry us too far to describe here the details of this method of analysis, and readers must be referred to Freud's *The Interpretation of Dreams*.

1083] The cause of the interference with the reaction must be sought for in the strong emotional tone of the complex. Individuals with good powers of introspection often affirm that they could not respond quickly, because of the sudden crowding into consciousness of a number of words among which they could find none suitable for the reaction. This is easily understood, for strong affects always collect numerous associations around them, and, on the other hand, an assemblage of associations is always accompanied by an intense emotional tone. In some cases we have an opposite condition from the above, and the subjects are not able to react because of a vacuum in consciousness, in which event the complex hinders reaction by simply not appearing in consciousness. Thus the underlying thought-complex sometimes carries too much into consciousness, and at other times too little, in either case disturbing the uniform flow of psychic functions. It acts like a peace-breaker in the psychic hierarchy. Such being the behaviour of the complex under normal conditions, it is easy to understand how it may play the chief part in abnormal mental states based upon disordered affectivity.

1084] Lengthened reaction-time is not the only index of a complex. If the stimulus-word causes a sudden embarrassment and brings out some striking and unusual reaction-word, it is certain that a complex has been struck, so that any reaction out of the ordinary may also be regarded as indicating the presence of an emotional thought-complex.

1085] It is not infrequent to observe a lengthened or disturbed reaction also in the second reaction after some critical stimulus-word, so that we have a persistence of the affect to the next following reaction, a fact which also may be taken to indicate the existence of a complex.

1086] And, finally, we have in the method of reproduction another excellent aid for the discovery of the complex. When the series of stimulus-words has been finished, the list is gone over again, and the subject is simply asked to repeat the word he had given before in response to the stimulus. We then notice that where stimulus-words touched upon a complex, the memory plays false and the subject tends to react with some other word than the one first given. This paradoxical phenomenon depends altogether upon the influence of a strong emotional tone. The complexes are often unpleasant and create a natural resistance in the individual; but they are not always unpleasant or painful, and even with such complexes as the subject would be perfectly willing to reveal, there is yet an inhibition present which shows itself in like manner. The cause of defective reproduction must lie in the general nature of the complex as already described, in a certain independence of the complex, which comes and goes according to factors peculiar to it, and not at the behest of consciousness, and which yields the selfgenerated associations, and not such as are sought by consciousness. We—that is, our conscious selves—are on the whole in a sense the resultants of competitions in the unconscious.

1087] It is thus that affective factors present themselves everywhere in our associations; and it is of interest to ascertain whether the psychogalvanic reflex runs a parallel course with the complex indices just described; whether it does so regularly or has a preference for certain constellations; whether differences exist when a complex is conscious or unconscious, etc.

1088] Wherever possible, we have employed the pneumograph at the same time with the galvanometer in these association studies to determine whether parallel disturbances were present.

1089] The association question is many-sided, and there are numerous methods by which to study it. We shall try in the following pages to present our method and to confine ourselves more especially to our method of investigation, rather than to bring forward too prominently results which, owing to the small number of individuals examined, are valuable as case material but cannot be looked upon as having general application.

1. *The Results Obtained with Association Tests*

1090] (1) When the experiment is ended we measure the heights of the galvanometric curves and arrange them in a table, with other results of the tests. As the table shows, we made one repetition of the experiment in this instance; in other cases two repetitions were made.

1091] (2) We then determine the arithmetical average of the galvanometric deviations, which in this instance is 4.9 mm. These figures are naturally only relative and, with our apparatus, correspond to only one-half of the actual movement of the mirror of the galvanometer. (The actual figure would be 9.8 mm.)

Case 1.—Uneducated man, aged 40, normal, two series of word associations, each twenty-four words (Nine words given as example)

	Series I			Series II			
No.	Height of galv. curve in mm.	Reaction-time one-fifth sec.	Association	Reproduction	Height of galv. curve in mm.	Reaction-time one-fifth sec.	Reaction
1	9	9	table/chair	ditto	7	7	ditto
2	4	9	sit/on a chair	ditto	3	15	ditto
3	4	11	garden/vegetable	ditto	3	6	ditto
4	3	14	red/apple	ditto	4	5	ditto
5	3	9	write/with pencil	ditto	4	7	ditto
6	6	40	full (no reaction)		2	6	cask
7	3	8	good/sugar		9	9	apple
8	6	6	forest/wood	ditto	4	5	ditto
9	5	10	tavern/drink	ditto	2	5	ditto

1092] (3) We then determine the probable average (Kraepelin) of the reaction-times in the following manner: The figures are arranged in a column in the order of their size, and the middle number is taken, which in this instance is 1.8 seconds. The probable is here preferred to the arithmetical average, because occasionally very high numbers occur in such tests, where the reaction-times are much more liable to increase than to diminish. An arithmetical average would be unduly influenced by the occasional presence of one or more large numbers, and would not give us the actual average of the reaction-time.

1093] (4) In the second series the average of the galvanometer deviations was 4.8 mm., and that of the reaction-times 1.2 seconds. We observe, therefore, a reduction in the average height of the galvanometer curve, which is clearly due to lessening of the power of the stimulus in the repetition. The same phenomenon is also seen in the average of the reaction-times, which is shortened. The fact that every reaction is accompanied by a galvanometer movement is due to the emotion of attention which accompanies each reaction and is great enough to produce notable physical changes.

1094] (5) We note that in the second series certain associations (the sixth and seventh) are repeated with a change of words. These defective or changed reproductions indicate that the psychological constellation for the respective associations had changed in the short time (a little over one-half hour) that had elapsed since the first series had been given. *We* know that associations which belong to certain complexes are those that may, because of inner conditions, suffer change within a short period of time. We may, therefore, expect that such false reproductions carry with them particular emotional phenomena; and this is actually the case here. The arithmetical average of the altered reproductions is 5.7 mm., while in the first series the average for the same associations was 4.5 mm. Furthermore, the altered reproductions in the second series show an excess of some 0.8 mm. over the average of the stimulation of the first series. The average of the reaction-times for the altered reproductions is 1.2 seconds, and for the correct reproduction 1 second, as would be expected. We learn from this that the supposition that the altered reproductions are affective phenomena would seem to be justified. We will not here enter into details in relation to the psychoanalysis of such manifestations, as we do not wish to forestall an especially careful study of this question now being made in this clinic by Binswanger.[21]

1095] (6) From the above consideration one would also expect that those associations which are changed in the repetition should also present some sort of affective signs in the first series; but, contrary to our expectation, we see in this case that the average height of the galvanometer deviation for the words subsequently changed in repetition is 4.8 mm., while the average for the unaltered reproductions is 5 mm. This difference is, of course, small, and no particular deduction could be drawn from one case. It is to be noted that the average reaction-time for the associations subsequently wrongly reproduced is 1.9 seconds, and for the words correctly reproduced 1.8 seconds. Perhaps there is here a slight indication of the phenomenon to which we refer.

1096] (7) In the preceding paragraphs we have frequently intimated that there is a certain connection between affectivity and the length of reaction-time, and this has been already carefully determined in the work of one of us.[22] One may expect to have, as a rule, large galvanometer curves with long reaction-times, always, however, with the limitation that only such lengthened reaction-times are considered as are connected with associations that directly excite complexes, and not the long reaction-times which may follow immediately after reactions that excite complexes. These latter are frequent and are examples of perseveration. In order to discover the actual complex-exciting association it is necessary to employ the psychoanalytic method, and for this purpose a more suitable material is needed than is at our disposition. We, therefore, content ourselves here with simply determining the average height of all galvanometer curves in relation to reaction-times which lie respectively above and below the probable average.

1097] In Series I, the average of galvanometer curves connected with long reaction-times is 4.5 mm., and with short reaction-times 6.1 mm.

1098] In Series II, the galvanometer curves with long reaction-times average 5.7 mm., and with short reaction-times 4.4 mm.

1099] The two results are contradictory. The cause of this lies in factors already alluded to and in other difficulties which must be the subject of later study.

1100] (8) The alteration of the psychological constellation of Series II already mentioned may be manifested in the galvanometer curve alone, without any change in the reproductions. This matter might be thus explained. In the first trial only certain meanings are attached to the stimulus-word by the subject; i.e., not all of the associations belonging to it are excited at the first trial, while at the second trial another series of new connections may be aroused. We very often meet this phenomenon in our psychoanalytic investigations.

1101] It is of the greatest importance for the study of intellectual processes in the individual to know how his associations are presented to consciousness, whether he has quick and complete command of all related associations. This point is of the utmost value for testing intelligence, since many persons may appear to be stupid during investigation because their associations are not at immediate command, and on the other hand stupid persons may seem to be relatively intelligent simply because they have good command of their associations. We may perhaps also expect to discover important differences between educated and uneducated intellects; the galvanometric experiments seem to open to us endless vistas.

1102] In this case 41.6 per cent of the associations in Series II show an increased galvanometric curve with an average plus difference of 2.3 mm. It is possible that later investigations may show us that this result has considerable psychological significance for the individual, because this subject was quite unintelligent.

1103] (9) After a marked galvanometric deviation we frequently observe that there is an inclination to successive large curves, if the succeeding stimuli are not too quickly given. This is not unexpected because it is a general psychological experience that strong affects induce great sensitiveness. If therefore we take the average of the curves which follow unusually strong galvanometer curves and compare them with the arithmetical average of all the curves, we find that after unusually high curves, the average height in Series I is 5 mm. and the reaction-time two seconds in contrast with the general averages of 4.9 mm. and 1.8 seconds. In Series II these figures are reversed, for here the average has a difference of plus 0.6 mm. while the average of the reaction-times shows a difference of minus 0.5 seconds. The relations are not quite definite.

1104] (10) The whole of Series I shows a rather uniform course, for the average of distribution amounts only to 1.6. The deviations are relatively not very high. The highest curve is 12 mm., and the association connected with it is *stupid / am I*, which was for this individual a clear egocentric stimulus which evidently struck a strong emotional complex.

1105] Fig. 12 is a portion of the curve in this case. In this, one notes the even course and uniform emotional value of each association. The accompanying pneumographic curve is undisturbed.

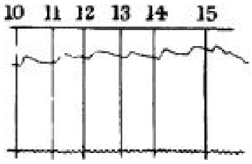


FIG. 12. Portion of curve in word association of a normal subject

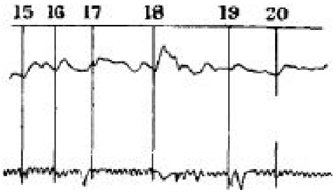

FIG. 13. Portion of curve corresponding to the association *stupid / am I*

1106] Fig. 13 shows the portion of the curve in which the association *stupid / am I* (reaction No. 18) occurred. This portion is marked by a very high many-pointed wave. The pneumographic curve is altered here, as it is also in reaction No. 19, though the latter has little emotional tone. But No. 19 has, however, a very long reaction-time (4.8 secs.), which is to be looked upon as a persisting intellectual disturbance from reaction No. 18. We observe here one of the numerous instances where the pneumographic curve and the reaction-time show evident disturbances, while the galvanic curve is unaffected. According to our hypothesis, this is owing to the fact that the galvanometer indicates only acute affective conditions, and not the more lasting intellectual after-effects, these latter being often well registered by reaction-time and pneumograph. The reaction-time shows how long the mind requires to detach itself from its conscious or unconscious preoccupation, and turn to the new stimulus. The respiration, because of its close relation to consciousness (susceptibility to voluntary influences), is also affected by intellectual processes, while the galvanometer seems to be influenced directly only by the unconscious.

Case 2.—Uneducated but rather intelligent man, aged 38

1107] (1) We have arranged in the following table the results of three series of associations of twenty-four words each:

Series I	Arithmetical average of galvanometer curves	5.6 mm.
Series II	Arithmetical average of galvanometer curves	7.2 mm.
Series III	Arithmetical average of galvanometer curves	5.9 mm.
Series I	Probable average of reaction-times	1.8 sec.
Series II	Probable average of reaction-times	1.3 sec.
Series III	Probable average of reaction-times	1.0 sec.

1108] The reaction-times are what we expect, but the galvanic curves show an unexpected increase in the second series. Our first supposition would be that this is owing to some physical change; for instance, better contact from increased warmth of the hands, or a change of posture of the body that increased the pressure of the hands upon the electrodes. Such conditions may not only interfere with the experiment, but also render comparison of results difficult. But it is also possible that the psychological constellation changed in the second series, causing thereby greater deviation of the galvanometer. If we take the first fifteen curves of Series II, we find the average to be 4.7 mm., which is much less than the average of Series I. But if we take the last nine curves of Series II, we find the average to be 11.3 mm., and that the cause of the great difference lies where the principle of loss of power in repeated stimulation does not seem to be effective. It is possible that after the fifteenth reaction there was a physical disturbance, which increased the height of the curves.

1109] We find that the probable average of the reaction-times of the first fifteen and last nine reactions both amount to 1.8 seconds, while the average of the galvanometer curves of the first fifteen reactions shows only a difference of minus 0.2 mm., as compared with the last nine curves. Now, if a physical change occurred toward the end of Series II, we might expect no change in the purely psychological reaction-times. This is, however, not the case. For the increased galvanic curves in the last nine reactions correspond to an increase of the reaction-times (1.4 seconds, as compared to 1 second of the first fifteen reactions). There is, therefore, a parallel between the galvanometer increase and the increased reaction-times, from which we may conclude that the increase depends upon an altered psychological constellation.

1110] We have already mentioned that a change in the constellation is due to the arousing of complexes. The reactions occur in this wise:

		SERIES I			SERIES II	
No.	Associations	Reaction-time	Gal. curve	Reproduction	Reaction-time	Gal. curve
1	money/round	1.8 sec.	3 mm.	ditto	1.2 sec.	12 mm.
2	high/tree	1.4 sec.	7 mm.	ditto	1.4 sec.	4 mm.
3	go out/morning	2.0 sec.	8 mm.	ditto	1.4 sec.	6 mm.
4	floor/dirty	1.8 sec.	5 mm.	ditto	1.8 sec.	9 mm.
5	wages/large	1.2 sec.	6 mm.	ditto	1.2 sec.	19 mm.
6	pay/debts	3.4 sec.	9 mm.	ditto	3.0 sec.	15 mm.
7	apple/red	2.4 sec.	5 mm.	ditto	1.4 sec.	27 mm.
8	nurses/many	1.6 sec.	4 mm.	ditto	1.8 sec.	5 mm.
9	five/small	1.8 sec.	5 mm.	ditto	1.2 sec.	5 mm.

1111] While as a rule the reaction-times are shortened in Series II, the galvanometer curves are higher. It seems as if the affects first really manifested themselves in Series II after having been inhibited in Series I. As is shown, the largest increases are connected with the associations *money / round*, *floor / dirty*, *wages / large* (the subject is an attendant or nurse and receives small wages), *pay / debts*, *apple / red*, and *nurses / many*. It is easy to understand that five of these associations might arouse strong sentiments. The strong reaction with *apple / red* is incomprehensible. But we have frequently noticed that quite indifferent associations following immediately upon strong emotional associations show in repetition sudden increase of galvanic reaction, as if the emotional tone were postponed. It is possible that we have such a phenomenon here, but we have no means of proving it. Affects are always inhibited if some other strong emotional complex displaces them. This was evidently the case here, because the unusual experiment excited the subject, so that he probably did not grasp the stimulus-words in all their personal relations. In Series II he was quieter and could comprehend better, in consequence of which emotional tones were more easily developed than before. This phenomenon is theoretically very important, since it indicates how affects are repressed in normal persons. Inhibition of affects plays a powerful role in psychopathology. (See the works of Freud, Bleuler, and Jung.)

1112] This experiment also illustrates well that reaction-time and galvanometer curve do not mean the same thing. We see here again how clearly the reaction-time reveals a greater intellectual freedom than in Series II, whereas the galvanometer curves are considerably higher than those of Series I.

	Galv. Curve	Reaction-time
(2) The altered reproductions of Series II average	6 mm.	1.7 sec.
The altered reproductions of Series III average	7 mm.	1.0 sec.
The unchanged reproductions of Series II average	7.3 mm.	1.3 sec.
The unchanged reproductions of Series III average	5.8 mm.	1.3 sec.

1113] Here, too, the relations are somewhat obscure, which may be owing to the occurrence of very few altered reproductions. Only half of the above numbers coincide with our expectations.

(3) Galvanometer curves with long reaction-times average in Series I	6.4 mm.
Galvanometer curves with short reaction-times average in Series I	6.4 mm.
Galvanometer curves with long reaction-times average in Series II	8.1 mm.
Galvanometer curves with short reaction-times average in Series II	4.2 mm.
Galvanometer curves with long reaction-times average in Series III	6.8 mm.
Galvanometer curves with short reaction-times average in Series III	4.1 mm.

1114] The first test is undecided, but the two following present figures which correspond with our expectation. (In Case 1 above recorded the first test also gave a contradictory result.)

1115] (4) In Series II, 41.6 per cent of the associations show an average difference of plus 3.2 mm. compared with Series I. In Series III, 45.8 per cent of the associations show a difference of plus 2.6 mm. as compared with Series II.

1116] These figures prove, as already mentioned, that Series II presents a considerably altered constellation. In Series III there are still more psychological constellations changed. It is to be regretted that there was not a much larger material at hand for the further investigation of matters so important for the psychology of the individual.

(5) Series I. Probable average of reaction-times in associations with unusually high galvanometer curves	2.2 sec.
Series I. Arithmetical average of the corresponding galvanometer curves	5.2 mm.
Series II. Probable average of reaction-times in associations with unusually high galvanometer curves	1.6 sec.
Series II. Arithmetical average of the corresponding galvanometer curves	12.0 mm.
Series III. Probable average of reaction-times in associations with unusually high galvanometer curves	0.8 sec.
Series III. Arithmetical average of corresponding galvanometer curves	7.0 mm.

1117] The curves in Series II and III do not, while those of Series I do, correspond to expectation. The reaction times in Series I and II are what we anticipate. Therefore, of six items, four coincide with our expectation.

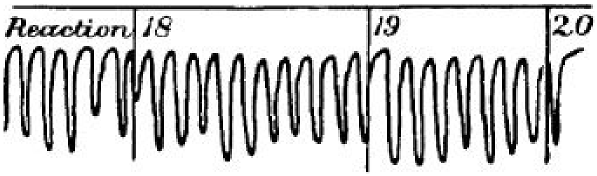

FIG. 14. Portion of Pneumographic curve in Case 2 (word association, normal individual)

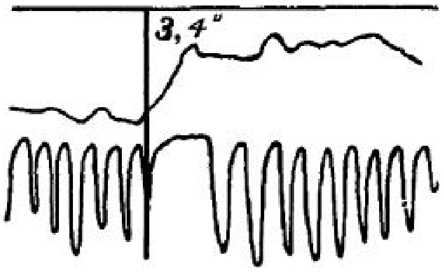

FIG. 15. Galvanic and pneumographic curve corresponding to the word association *pay / debts*. (Figs, 14 and 15 are reproduced the actual size of the tracing)

1118] *(6)* Series I. Presents in general a uniform character. The average of distribution is only 1.5 mm. The highest curve measures 9 mm., and this is connected with the association *pay / debts*, which, as we have seen, also preserves its high emotional value in Series II.

1119] Series II is much more irregular. The average of distribution is 3.8 mm., a very high figure, which well illustrates the general irregularity of the series. The highest curves of this series have already been described.

1120] Series III presents, on the other hand, another series with uniform character. The average of distribution is only 1.8 mm. The highest curve occurs with the association *wages / large*, and amounts to 11 mm., and in Series II it also had a high value. Such concord shows clearly that these figures are not accidental.

1121] The pneumographic curve presents no peculiarities. In Series I, with indifferent associations, this curve has the aspect shown in fig. 14.

1122] Fig. 15 is the galvanometric and pneumographic curve belonging to the association *pay / debts*. In this we observe a marked inhibition of respiration during and after the critical association.

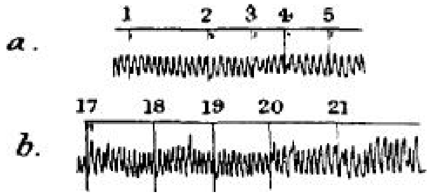

FIG. 16. (*a*) Respiratory curve, with word associations No. 1 to 5 in Case 2. *(b)* Curve, same case, associations No. 17 to 21

1123] The psychic excitation referred to previously in the last nine associations of Series II seems to manifest itself also in the pneumographic curve, as apparently evidenced in figs. 16*(a)* and 16(b).

1124] Fig. 16(*a*) is a portion of the respiratory curve during associations 1 to 5. Fig. 16(b) represents associations 17 to 21. The difference is marked. We can hardly be mistaken in supposing that the change in respiration is the expression of a certain excitation, which is in harmony with our previous assumptions.

Case 3.—*Uneducated man of moderate intelligence, aged 28, lively, excitable temperament. Normal. Three series of associations, each with twenty-three words*

1125]

(1) Series I. Arithmetical average of galvanometer curves	14.2 mm.
Series II. Arithmetical average of galvanometer curves	6.5 mm.
Series III. Arithmetical average of galvanometer curves	2.0 mm.
Series I. Probable average of reaction-times	2.4 sec.
Series II. Probable average of reaction-times	2.2 sec.
Series III. Probable average of reaction-times	2.0 sec.

The curves of Series I reach a considerable height, but the stimulus diminishes rapidly and intensely in power in the succeeding series. The reaction-times shorten uniformly, but are still in general somewhat long, as we observe not infrequently among emotional people.

1126]

	Galv.	Reaction time
(2) The altered reproductions of Series II average	7.9 mm.	2.0 sec.
The unchanged reproductions of Series II average	1.8 mm.	2.2 sec.
The altered reproductions of Series III average	3.5 mm.	2.2 sec.

The unchanged reproductions of Series III average	1.3 mm.	2.1 sec.

The galvanic curves correspond in both series to our expectation, but the reaction-times in Series II are contradictory, which, however, is changed if we do not employ the probable average (as is ordinarily done by us in all cases) but the arithmetical average, when the average time for altered reproduction is 2.8 sec., and for the unchanged only 2.4 sec.

1127]

(3) The galvanic curves with long reaction-times in Series I average	17.8 mm.
The galvanic curves with short reaction-times in Series I average	12.7 mm.
The galvanic curves with long reaction-times in Series II average	9.8 mm.
The galvanic curves short reaction-times in with Series II average	3.6 mm.
The galvanic curves with long reaction-times in Series III average	2.1 mm.
The galvanic curves with short reaction-times in Series III average	0.0 mm.

All of these figures are in perfect accord with our hypothesis.

1128] (4) In Series II, 17.3 per cent of the associations have an average difference of plus 5.8 mm. In Series III, 17.3 per cent of the associations have an average difference of plus 2.8 mm.

1129] These figures show that the constellation in the latter series is not very much changed, with the exception of a few associations. We may conclude that all the strong emotional relations of the stimulus-words were brought out in the first test. We should say here that Case No. 3 was well accustomed to this kind of experiment, while cases No. 1 and No. 2 were not.

1130]

(5) Series I. Probable average of reaction-times following associations with unusually high galvanic curves	2.8 sec.
Series I. Arithmetical average of the corresponding galvanic curves	22.3 mm.
Series II. Probable average of reaction-times following associations with unusually high galvanic curves	1.8 sec.
Series II. Arithmetical average of the corresponding galvanic curves	11.4 mm.
Series III. Probable average of reaction-times following associations with unusually high galvanic curves	1.2 sec.
Series III. Arithmetical average of the corresponding galvanic curves	1.7 mm.

The galvanic curves are what we would expect in Series I and II but not in Series III. The reaction-time is what we expect only in Series I.

1131]

	Galv.	Reaction-time

(6) Series I. Average of associations altered in subsequent reproduction	14.2 mm.	2.4 sec.
Series I. Average of association unchanged subsequently	13.5 mm.	2.0 sec.
Series II. Average of associations altered in subsequent reproduction	8.7 mm.	2.2 sec.
Series II. Average of associations unchanged subsequently	3.6 mm.	2.0 sec.

All of these figures coincide with what we expect.

1132] (7) The general course of Series I is very irregular. The average of distribution is 7.6, the highest number we have yet observed. In the tests with Cases 1 and 2 the various phases of stimulation were shown in strong, but much differentiated, emotions, but in this case with a lively temperament there was a continual and marked fluctuation of emotions, and hence the high average of distribution.

1133] Series II is more uniform, and the average of distribution is 5.4, and in Series III this average is only 2.3.

1134] The highest galvanic curve in Series I measures 51.5 mm. and is connected with the association *the sun / burns*. Why there should be here so strong a reflex innervation could not be understood without further examination. The subject himself could not explain why he had any particular emotion at this moment. But the connection was shown in the following associations. The other high curves (37, 21 and 18 mm.) occurred with the associations *floor / parquet, pay / write, warm / the stove*. These three associations showed constant and similar disturbances in all three series, as illustrated in this table:

	Series I			Series II			Series III	
	Galv.	Reaction-time	Reproduction	Galv.	Reaction-time	Reproduction	Galv.	Reaction-time
floor	37 mm.	3.0 sec.	ditto	13 mm.	3.2 sec.	ditto	2.5 mm.	3.0 sec.
warm	18 mm.	1.2 sec.	ditto	31 mm.	2.2 sec.	ditto	7.0 mm.	2.0 sec.
pay	21 mm.	2.0 sec.	ditto	4.5 mm.	0.8 sec.	ditto	7.5 mm.	2.2 sec.

1135] All the reproductions were altered. With one exception all of the galvanometer curves were considerably above the averages for each of the series. As to the nine reaction-times, four were above, and two coincided with the probable averages. It seemed justified from these observations to assume that a strong emotional complex lay behind them. But when questioned the subject answered that he had had no particular thoughts in connection with these reactions, and was evidently unconscious of any special complex. Yet even if a subject asserts that no complex is present, this is not conclusive in the face of so many indications pointing to interference by a complex. In this instance we distracted his attention from the matters in hand and asked what personal significance the word *floor* had for him, when suddenly he said with surprise and embarrassment that recently a *stove* in his dwelling had become defective and *burned* the *floor* to such an extent that he had not only to *pay* for a new stove, but also for an entire new floor which was a hardship for him. Besides this there had been great danger from fire. Thus all the disturbances above related were perfectly explained, including the strong emotional tone of the association *the sun / burns*.

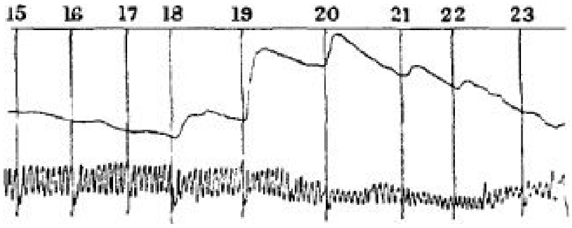

FIG. 17. Portion of a curve to show emotional effect of certain word associations

1136] We learn from this interesting episode that the galvanic phenomenon, like reaction-time and alteration of reproductions, may give evidence of the existence of an unconscious complex. We cannot go into further detail regarding this fact here, but the investigations of Binswanger already mentioned also throw much light on the subject.

1137] The group of associations described above gives an unusually fine picture in Series II of emotional effect upon the curves (fig. 17). At the beginning we have indifferent reactions. Reaction No. 18 is *floor*, 19 *warm*, 20 *wages / small*, and 21 *pay*.

1138] The respiratory curve also shows the reactions very clearly. In general, inspiration is increased, which is especially characteristic for this particular case in connection with expectant attention. The condition during the unconscious complex excitation seems therefore to have had a certain resemblance to the tension of expectation. An example of this tension of expectation in this case at the beginning of a test is shown in fig. 18.

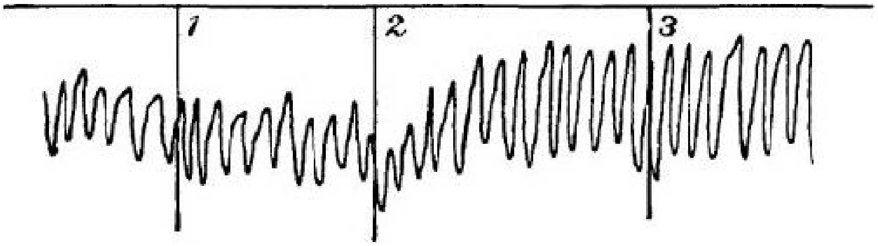

FIG. 18. Expectation curve in Case 3 (reproduced actual size of tracing)

Case 4.—*An educated woman, aged 25, used to these experiments. Three series of word associations, eighteen words in each*

1139]

(A) Series I. Arithmetical average of galvanic curves	6.8 mm.

Series II. Arithmetical average of galvanic curves	1.9 mm.
Series III. Arithmetical average of galvanic curves	0.9 mm.
Series I. Probable average of reaction-times	1.2 sec.
Series II. Probable average of reaction-times	1.0 sec.
Series III. Probable average of reaction-times	1.0 sec.

The galvanic curves show very rapid diminution, while the reaction-time is very short and the lowest limit is soon reached.

1140]

	Galv.	Reaction-time
(B) The altered reproductions of Series II average	7.5 mm.	1.6 sec.
The unchanged reproductions of Series II average	1.6 mm.	1.0 sec.
The altered reproductions of Series III average	0.0 mm.	1.0 sec.
The unchanged reproductions of Series III average	1.0 mm.	1.0 sec.

The result in Series II is what we expected, but this is not true of Series III, perhaps because only very few altered reproductions occur.

1141]

(C) The galvanic curves with long reaction-times in Series I average	11.6 mm.
The galvanic curves with short reaction-times in Series I average	5.2 mm.
The galvanic curves with long reaction-times in Series II average	5.4 mm.
The galvanic curves with short reaction-times in Series II average	0.8 mm.
The galvanic curves with long reaction-times in Series III average	1.0 mm.
The galvanic curves with short reaction-times in Series III average	1.5 mm.

The figures in Series I and II are what we expected, but not in Series III, perhaps because most of the curves had already sunk to zero.

1142]

(D) In Series II, 5.5 per cent of the associations show an average plus difference of	6.0 mm.
In Series III, 11.1 per cent of the associations show an average plus difference of	2.7 mm.

In this case also we note a great readiness of the association to appear fully on the first stimulus, so that the constellation does not change much later on.

1143]

(E) Series I. Probable average of reaction-times following associations with unusually high galvanometer curve	1.1 sec.
Series I. Arithmetical average of corresponding galvanometer curves	6.5 mm.
Series II. Probable average of reaction-times following associations with	1.0 sec.

unusually high galvanometer curves	
Series II. Arithmetical average of corresponding galvanometer curves	1.2 mm.

The figures in Series III are omitted, because most of the galvanic curves were reduced to zero. The figures given in the above two series do not accord with our expectation.

1144]

	Galv.	Reaction-time
(F) Series I. Average of associations altered in subsequent reproductions	4.3 mm.	4.0 sec.
Series I. Average of associations unchanged subsequently	4.4 mm.	1.2 sec.
Series II. Average of associations altered in subsequent reproductions	6 mm.	1.2 sec.
Series II. Average of associations unchanged subsequently	1.6 mm.	1.0 sec.

These figures are what we should expect.

1145]

(G) Average of distribution in Series I	5.5
Average of distribution in Series II	2.2
Average of distribution in Series III	1.6

1146] We find as usual the greatest variation in the figures in the first series. With lessening power of the stimulus in the repetitions, a levelling tendency is manifested as regards this variation in the power of the stimulus. The highest curves are found in the following associations:

	SERIES I			SERIES II			SERIES III	
	Galvanometer	Reaction-time	Reproduction	Galvanometer	Reaction-time	Reproduction	Galvanometer	Reaction-time
ball/dance	4.3 mm.	4.0 sec.	0	7.5 mm.	1.6 sec.	ditto	12 mm.	0.8 sec.
dress/red	9.0 mm.	1.8 sec.	ditto	2. mm.	0.6 sec.	ditto	0 mm.	0.8 sec.
pretty/ugly	7.5 mm.	1.4 sec.	ditto	3. mm.	0.8 sec.	ditto	3 mm.	1.2 sec.

1147] The galvanic curves are much higher than the average in all three series for the association *ball / dance*. The intensity of the affect here is shown by the fact that while fifteen out of eighteen reactions in the last series caused no deviations of the galvanometer, this particular association induced a deflection of 12 mm. In this instance the subject expected to go in a few days to a fancy dress ball, but despite much search had not yet found a suitable costume. She was, therefore, in a state of anxiety concerning it. The association *dress* and *pretty* are self-evident.

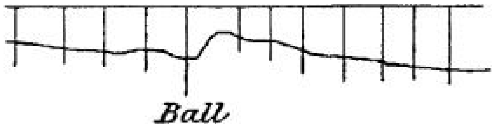

FIG. 19. Wood association *ball / dance* in Case 4

1148] The reaction-times were rapidly shortened in the repetitions, because of her natural aptitude in speech. It is evident that at times the galvanic phenomenon is more helpful than lengthened reaction-times in demonstrating emotional states.

1149] Fig. 19 is a curve from Series III in this case representing the well-marked association *ball / dance*. Repetition of the association test is to be recommended when one desires to bring out more clearly very strong emotional complexes.

2. *Resume of the Tests with Word Associations in Normal Individuals*

1150] Our limited material, consisting of the word associations in one educated woman and three uneducated men, leads us to bring forward with much reserve a *résumé* of our results. We know that they must be regarded as only preliminary, and as being of questionable value, but at the same time they foreshadow features of interest for future enquiry and investigation. Our intention in this work is chiefly to point out indications, and our presentation of results must be taken in this sense.

1151] (1) The average positive difference of a galvanic curve, produced by an association whose reaction-time exceeds that of the probable average of the same series, is 2.7 mm.

1152] Taking into consideration the above-mentioned limitations this figure seems to express that in certain cases there is a clear parallelism between the length of reaction-time and the height of the galvanometer curve. This method appears, therefore, to afford a psychophysical proof of the hypothesis of one of us (Jung), that very long reaction-times are affective phenomena.

1153] (2) Altered reproductions show an average difference of 2 mm. over unchanged reproductions.

1154] (3) Such associations as are changed in the reproductions of the following series present an average difference of plus 6.8 mm. over such as are reproduced subsequently unchanged.

1155] These two figures, especially the last, seem to offer a psychophysical confirmation of the hypothesis of one of us (Jung), that altered reproductions are affective phenomena.

1156] The remaining methods embodied in the text of our work have little right to a special summing up here, because of the scantiness of our material, and also because of some contradictions in our results.

3. *Word Associations in Dementia Praecox*

1157] There were but two of our cases of paranoid dementia that could be used for a test of word associations with the galvanometer.

Case 1.—*Male, aged. 36, very intelligent, academic education. Speech well preserved. Two series of associations, with twenty-four words each*

1158]

(A) Series I. Arithmetical average of heights of galvanometer curve	11.6 mm.
Series II. Arithmetical average of heights of galvanometer curve	4.6 mm.
Series I. Probable average of the reaction-times	6.6 sec.
Series II. Probable average of the reaction-times	4.8 sec.

The average height of the galvanometer curves falls in both series within normal limits, which is not the case with the reaction-times showing excess. Our four normal subjects presented the following average:

Series I. Galvanometer curves 7.8 mm.	Reaction-times 1.8 sec.
Series II. Galvanometer curves 5.1 mm.	Reaction-times 1.4 sec.

From these figures it is seen that the patient offers a strong contrast in the length of the reaction-times.

1159]

	Galv.	Reaction-time
(B) The altered reproductions in Series II average	4.7 mm.	6.0 sec.
The unchanged reproductions in Series II average	3.4 mm.	2.8 sec.

These figures coincide with the normal, and are what we should expect. But we note that the unchanged reproductions present a much lower value in the reaction-time than the altered reproductions.

1160]

(*C*) The galvanometer curves with long reaction-times in Series I average	13.1 mm.
The galvanometer curves with short reaction-times in Series I average	10.3 mm.
The galvanometer curves with long reaction-times in Series II average	3.8 mm.
The galvanometer curves with short reaction-times in Series II average	4.0 mm.

In this table the figures in Series I, but not those in Series II, are what we expect.

1161]

(*D*) In Series II, 12.5 per cent of the associations show an average plus difference of 4.5 mm.

1162]

(*E*) Series I. Probable average of reaction-times following associations with unusually high galvanic curves	4.0 sec.
Series I. Arithmetical average of the corresponding galvanic curves	10.0 mm.
Series II. Probable average of reaction-times following associations with unusually high galvanic curves	7.6 sec.
Series II. Arithmetical average of the corresponding galvanic curves	3.2 mm.

In this table, only the reaction-time of Series II is in accordance with our expectation.

1163]

	Galv.	Reaction-time
(F) Series I. The associations with altered reproductions in the following series average	9.8 mm.	6.6 sec.
Series I. The associations with unchanged reproductions in the following series average	13.5 mm.	5.4 sec.

Only the reaction-time here is what we expect.

1164] (G) The average of distribution in Series I was 5.8. The average of distribution in Series II was 3.4. These figures are similar to those of Case 4 among the normal.

1165] The highest galvanic curve occurred with the reaction *love / a psychic process* (30 mm.), and here was also the longest reaction-time (27.2 sec.). The next highest curve was connected with the reaction *wife / marriage-law* (29 mm.). The patient is single, and having had with *love* a strong emotional tone, it was not surprising that *wife* should also evince a similar intensity. Another high curve was found in the association *sick / at-heart* (26 mm.). The patient still had some insight into his condition, and knew that he was confined in the asylum because of his mental malady, hence the strong emotion connected therewith. The word *handsome* produced a curve of 25 mm. The patient is very vain, and pays extraordinary attention to his dress. The contents of the association present the symptoms of affectation, which is evident from his external appearance. Most of his associations showed a definition character which, in educated people, always indicates a certain amount of affectation. The following are examples:

write	activity
shoes	footwear
hat	an article of clothing
house	building construction
to sit	condition of rest
money	medium of exchange
proud	adjective

1166] The long reaction-times may be due to this affected manner of expression, though this can hardly be the only cause.

Case 2.—*Woman, single, aged 62, uneducated, medium intelligence. Speech mingled with neologisms. Three series of associations with twenty-five words each*

1167]

(A) Series I. Arithmetical average of the galvanic curves	7.9 mm.
Series II. Arithmetical average of the galvanic curves	3.6 mm.
Series III. Arithmetical average of the galvanic curves	2.5 mm.
Series I. Probable average of reaction-times	10.8 sec.
Series II. Probable average of reaction-times	6.4 sec.
Series III. Probable average of reaction-times	6.0 sec.

As in the former case, the galvanic deviations are of medium height, while the reaction-times are extraordinarily long.

1168]

	Galv.	Reaction-time
(B) The altered reproductions in Series II average	3.6 mm.	6.6 sec.
The unchanged reproductions in Series II average	3.6 mm.	5.2 sec.
The altered reproductions in Series III average	2.5 mm.	7.4 sec.
The unchanged reproductions in Series III average	2.4 mm.	4.6 sec.

The reaction-times accord with our expectation, as in the former case, much better than the galvanometer curves.

1169]

(*C*) The galvanometer curves with long reaction-times in Series I average	9.6 mm.
The galvanometer curves with short reaction-times in Series I average	6.0 mm.
The galvanometer curves with long reaction-times in Series II average	4.7 mm.
The galvanometer curves with short reaction-times in Series II average	2.6 mm.
The galvanometer curves with long reaction-times in Series III average	2.8 mm.
The galvanometer curves with short reaction-times in Series III average	2.5 mm.

The figures in all three series are what we expect.

1170]

(*D*) In Series II, 28.0 per cent of the associations show an average plus difference of 4.7 mm. In Series III, 24.0 per cent of the associations show an average plus difference of 4.8 mm.

1171]

(*E*) Series I. Probable average of reaction-times following associations with unusually high galvanic curves	11.6 sec.
Series I. Arithmetical average of corresponding galvanic curves	11.8 mm.
Series II. Probable average of reaction-times following associations with	5.8 sec.

unusually high galvanic curves	
Series II. Arithmetical average of corresponding galvanic curves	3.7 ram.
Series III. Probable average of reaction-times following associations with unusually high galvanic curves	8.0 sec.
Series III. Arithmetical average of corresponding galvanic curves	2.5 mm.

Twice the reaction-times are what we expected, the galvanic curves only once, and in Series III the arithmetical average is the same.

1172]

	Galv.	Reaction-time
(F) Series I. The associations with altered reproductions in the following series average	9.0 mm.	10.4 sec.
Series I. The associations with unchanged reproductions in the following series average	6.3 mm.	12.4 sec.
Series II. The associations with altered reproductions in the following series average	3.3 mm.	6.6 sec.
Series II. The associations with unchanged reproductions in the following series average	4.0 mm.	4.8 sec.

We find in this table that only the galvanic curves in Series I and the reaction-times in Series II are what we expected.

1173] (G) The average of distribution in Series I was 4.9.

The average of distribution in Series II was 2.8.

The average of distribution in Series III was 1.6.

1174] The highest galvanic curve (21 mm.) is found in the association *sun / sun-time*, and here the reaction-time is 14.0 seconds. It is difficult to explain this excessive deviation. The preceding association is *stout / constitution* (15 mm., and 14.8 seconds reaction-time). The patient is very stout, which she thinks due to supernatural influences. She complains much of this “forced” disfigurement. In Series II these two associations caused no deviations, but in Series III *stout / constitution* suddenly induced the largest deflection of the whole series, viz., 14.5 mm., whereas the average was only 2.5 mm. There was a curve of 20 mm. with the association *ugly / disfigured by great suffering*, and with this a reaction-time of 12.0 seconds. The contents of this association are concerned with the same theme as *stout / constitution*. Another high curve occurred with *high / highest action* (19 mm. and reaction-time 11.2 seconds). This association was subsequently altered twice in the reproductions. It is connected with the delusion of the patient that she had accomplished the “highest work.”

1175] The associations are typically affected and show a distinctly morbid character. The following are examples:

diligent	high esteem—payment
love	to be lovable—wedding
snake	to point out as extraordinary
high	highest action—highest distinction
ugly	disfigured by great suffering

1176] *Résumé:* In our tests with word associations in the two cases of dementia praecox the only striking fact has been the great lengthening of reaction-times. In the relations between the galvanometer curves and associations we have found nothing different from the normal. From the material of Jung, who has analyzed a large collection of association experiments in dementia praecox, we learn that in by far the greater proportion of these cases there is no particular lengthening of reaction-time. Therefore a long reaction-time cannot be considered as characteristic for all cases of dementia praecox. It is of value in some cases. It is only present when the patients suffer from certain hindrances to thought, which are often present in this disease.

1177] When we examine the associations of such patients we find that the hindrance to thought (lengthened reaction-time) is especially manifested where complexes constellate the association, which is also the case in normal individuals. This phenomenon first led Jung to think that the specific pathological factor in dementia praecox depends upon some complex. A complex in fact plays a great role in the associations of our two patients here described. The reaction-times are extraordinarily long where connected with a complex. The complex constellations are also very numerous, as well as the altered reproductions related to them. In our normal cases we found an average of 30 per cent of altered reproductions in Series I, while the patients had 51 per cent. Besides this, the character of the associations presents abnormalities almost constantly, especially around the complexes.

1178] From these indications we may conclude that little of a pathological nature can be found in the general and regular mechanisms of thought, but rather in the manner and method of reaction of the individual to his complexes. We find in both of these patients an increased influence of the complex upon association, which corroborates the results of innumerable analyses of dementia praecox by Jung. This phenomenon has an important and general clinical significance, because, when carefully analyzed, nearly all the symptoms are found to be determined by an individual complex, often manifested in a very convincing way. This is particularly true for delusions and hallucinations. A series of other symptoms is more often dependent upon indirect disturbance of association by the complex. This state of affairs explains why we do not discover any elementary disturbances, even in quite intense mental disorder; the dementia is shown only in the most delicate psychological relations. Therefore we shall look in vain, for the present and for a long time to come, among these patients for simple, elementary disturbances common to all cases.

1179] NOTE. —Since this article was put into type we have found that Féré,[23] carrying a current through a subject with various sensory stimuli, made the following observation: “Il se produit alors une déviation brusque de l’aiguille du galvanomètre…. La même déviation se produit encore sous l’influence d’émotions éthéniques; c’est à dire qu’elle se produit dans toutes les conditions où j’ai signalé précédemment une augmentation de volume des membres mise en évidence par le pléthysmograph.” This clearly shows that Féré made the discovery two years before Tarchanoff.

FURTHER INVESTIGATIONS ON THE GALVANIC PHENOMENON AND RESPIRATION IN NORMAL AND INSANE INDIVIDUALS[1]

by Charles Ricksher and C. G. Jung

1180] The changes produced by various causes in the electrical resistance of the human body have been studied for many years, but as yet no definite results have been reached. Charles Féré was the first to report on the changes produced by emotion. In a communication made to the Société de Biologie in 1888[2] he noted that there was a decrease in bodily resistance when various sensory stimuli were applied, and also that emotion produced a similar decrease. R. Vigouroux had been working on the problem of electrical resistance in the human body with patients from the Salpétrière and had reached the conclusion that the old view of resistance being caused by the epidermis was wrong and that the true cause was the condition of the superficial circulation. He thought that variations in resistance were caused by an increased or decreased superficial circulation. Féré accepted these conclusions and added that "l'étude de la résistance électrique peut trouver une application dans les recherches des psycho-physiologues."

1181] Nothing new was reported for several years. In 1890, A. Vigouroux published a report on the study of electrical resistance in melancholics but added nothing to our knowledge. Tarchanoff, Stricher, Sommer, and Veraguth have all summarized the work of the French investigators. The first person to do real psychological research using the galvanometer was Veraguth, who in 1906 worked with this instrument and with Jung's association experiments. In the same year work was begun in the Psychiatric Clinic in Zurich to try to determine the cause of electrical resistance of the body and the changes produced in the bodies of normal and insane individuals by different stimuli. The apparatus used consisted of a circuit containing a single low-voltage element, a Deprez-d'Arsonval galvanometer of high sensitivity, a shunt for lowering the oscillations of the mirror, and two brass plates upon which the subject of the test places his hands and thus closes the circuit. The galvanometer reflects a beam of light onto a celluloid scale to which is attached a movable slide with a visor, which, pushed by hand, follows the moving mirror-reflection. To the slide is attached a cord leading to what is called an ergograph writer, which marks the movements of the slide by means of a pen-point on a kymograph-drum fitted with endless paper. For measuring time a Jaquet chronograph was used and for the moment of stimulus an ordinary electrical marker.

1182] The problem of the cause of resistance was first approached; the results given are those obtained by Jung and Binswanger and are as yet unpublished. Resistance was found to vary greatly in different individuals with different conditions of the palmar epithelium. That the epidermis was the seat of resistance was proved by the fact that when the electrodes were placed under the skin resistance was enormously decreased. This was done by piercing the skin of each arm with a surgical needle and using the needles as electrodes.[3]

1183] The French investigators were unanimous in ascribing the changes in resistance to changes in the blood supply of an area, caused by dilation and contraction of the vessels, the greater the blood supply the lower the resistance and vice versa. That the blood supply was not a chief factor was proved by exsanguinating the area in contact with the plates with an Esmarch bandage, whereupon it was found that the galvanic phenomenon still appeared.

1184] That the changes in resistance are not due to changes in contact, such as pressure on the electrodes, is shown by the fact that when the hands are immersed in water, which acts as a connection to the electrodes, the changes in resistance still occur. Pressure and involuntary movements give a deflection entirely different from the usual result of an affective stimulus.

1185] The time that elapsed between a stimulus and the change in resistance, as shown by the galvanometer, suggested some change in the sympathetic nervous system or in some area controlled by it. The sweat-glands seemed to have most influence in the reduction of resistance. If the sweat-glands were stimulated there would be thousands of liquid connections between the electrodes and tissues, and resistance would be much lowered. Experiments were made by placing electrodes on different parts of the body, and it was found that the reduction in resistance was most marked in those places where most sweat-glands are located. It is well known that both emotion and sensory stimuli influence the various organs and glands, heart, lungs, sweat-glands, etc. Heat and cold also influence the phenomenon, heat causing a reduction and cold an increase in resistance. In view of these facts the action of the sweat-glands seems to be the most plausible explanation of the changes in resistance.

1186] The following experiments were made in the winter and spring of 1907, with a view to determining the effect on the galvanic phenomenon and respiration of a series of simple physical and mental stimuli in a number of normal and insane subjects. The galvanometric changes were noted by the apparatus described above. The respiration was recorded by means of a Marey pneumograph attached to the thorax and leading by means of a rubber tube to a Marey tambour, to which is attached a pen-point that writes on the kymograph-drum.

1187] The results of pneumographic experiments of various authors are very conflicting. Delabarre[4] found that attention to sensory impressions increased the frequency and depth of respiration. Mosso, in his work on the circulation in the brain, could come to no satisfactory conclusions. Mentz found that every noticeable acoustic stimulus caused a slowing of the respiration and pulse. Zoneff and

Meumann found that high grades of attention cause a very great or total inhibition of respiration, while relatively weaker attention generally produces an increase in the rate and a decrease in the amplitude of the respirations. Total arrest of respiration was found relatively more frequently in sensory than in intellectual attention. Martius notes great individual differences and comes to the conclusion that there is an affect type differing from the normal, shown by slowness of the pulse and respiration.

1188] The experiments of these authors were all made on a limited number of subjects, usually students. Our experiments with the pneumograph were generally made on uneducated men, attendants in the clinic, and our stimuli were quite different from those used by the other investigators. It is possible that the great difference in our results may in part depend on these facts.

1189] In our experiments care was taken to have the conditions as nearly equal as possible. It was found that different positions of the body, leaning forward or backward, for example, caused a change in the level of the respiratory curves. Slight movements of the body and of the limbs did not influence the curves. The tambour itself can cause changes in the recorded curves. The tambour must contain the same amount of air in every case, otherwise the curves will be different. The curve registered is not an exact one, owing to defects in the instruments. In deep inspirations the rubber covering becomes tense and, when the pressure in the chest changes, the elasticity of the rubber causes the respirations to be registered in a different way from that in which they really occur.

1190] It cannot be assumed that the respiratory curves represent ordinary normal respiration but only the kind of normal respiration to be expected under experimental conditions. No one can breathe naturally with a recording apparatus on his chest and with his attention more or less directed to it. The release from the tension of the experiment is seen at the end of the experiment when the respirations become deeper and the level of the curve changes. The pneumograph could not be used on women because of their clothing, nor could it be used with many of the insane subjects because of their excitability.

1191] The plethysmograph was not used because with it the sources of error are too numerous. Martius has shown that, even when the arm and instrument are encased in plaster of Paris, there occur involuntary movements that make correct interpretation of the results difficult.

1192] In the galvanic experiment many sources of error have to be considered. Chief among these is the deflection caused by movements of the hands. An increase or decrease in the pressure of the hands upon the electrodes causes an instantaneous change in the position of the reflection of the galvanic mirror. This change is sudden, and it is almost impossible to produce deliberately a change in the position of the reflection like one caused by an affective mental process. The natural change of position of the hands is shown by an almost vertical rise or fall of the galvanic curve as shown on the kymograph-drum. To prevent, as far as possible, involuntary changes of position, bags of sand were placed on the hands, thus preventing any but deliberate movements. It was found that quite extensive movements of the body could be made without influencing the galvanometric curve. Deep inspirations and sighs cause a greater or lesser rise in the curve. In the same curve a sigh occurring after an affective process seems to cause a more extensive rise than one occurring before. Deliberate long inspirations cause little or no disturbance. It must therefore be assumed that sighs are caused by some affective complex, or that they cause such a complex to come into consciousness or they produce an unconscious emotional condition.

1193] The subjects were physicians and attendants, as well as patients suffering from various mental diseases.

1194] The experiment may be divided into six parts: in each part a different stimulus or series of stimuli of the same kind, physical or psychological, was used. Before each stimulus or series of stimuli the subject was told in a general way what was going to happen. In many individuals, after a short period of waiting for a stimulus, there were changes in respiration and in the galvanic curve. These expectation-curves will be discussed later.

1195] The measurements of height are in each case the real, i.e., the vertical height. The respiratory rate is given as so many per centimetre, which is a purely comparative measurement. For the quiet periods we give the average rate per centimetre for ten centimetres at the beginning and end of each period.

1196] Part I of the experiment consists of a quiet period of four minutes. The subject was asked to sit as quietly as possible and was told that no stimulus was going to be applied. In Part II, the stimulus was a leaden weight allowed to fall about three feet onto the floor. In Part III, the subject was asked to say spontaneously, after a minute or so, a word or a short sentence, and then to remain quiet. Part IV consists of three physical stimuli: a low whistle, a weight dropped onto the floor, and a picture (picture post-card) shown to the subject. Part V consists of four sentences spoken by the investigator. The first two were usually some familiar proverb, such as “The pitcher goes often to the well but is broken at last”; the third and fourth were of a more critical nature as they referred directly to the subject himself or to his habits. In several cases single words, such as *eye* and *face*, were given. Part VI is again a quiet period of four minutes. The results of each part will be given here, and the normal subjects, fifteen in number, will be considered first.

NORMAL SUBJECTS

1197] *Part I*. The galvanometric curve is usually higher at the beginning than it becomes a short time later owing to feelings of expectation and tension caused by the unusual position and the strange experiment. As a rule the curve shows many irregularities caused by the subject's hand and body movements as he settles into a comfortable position; such movements are also the result of expectation, muscular tension (this is not, however, an important factor), and of various emotionally charged complexes. In the course of the quiet period there are seen oscillations of the galvanic mirror that cannot be accounted for by any movement of the hands or body, by any respiratory change, or any conscious thought or association. We have therefore attributed them to the indefinite *feeling* caused by some still unconscious complex. Everyone has experienced these vague feelings, sad or gay, that come without apparent cause, last only a short time, and are soon forgotten. Such a curve was clearly shown in the case of a well-educated physician, with a considerable power of self-analysis, who could not remember any affective thought that had occurred to him during the period.

1198] The inspirations at the beginning of the quiet period are usually deeper and more frequent than at the end. At the beginning they average 2.91 per cm. and at the end 2.79 per cm. The average height of the inspirations at the beginning is 12.41 mm., at the end 12.26 mm. In our cases the respiratory curve does not show any great or constant change of level.

1199] In *Part II* (stimulus a falling weight) the galvanometric curves show great individual differences. In one case, that of an attendant who was very nervous and frightened by the experiment, the galvanometric deflection was 54 mm. In another case, also of an attendant, but of a very phlegmatic disposition, the deflection was only 4.6 mm. The average deflection for fifteen subjects was 20.6 mm.

1200] The longest reaction-time, i.e., the time from the moment of stimulus to the beginning of the rise of the galvanic curve, varies from 1.5 to 5.5 seconds. This time, while showing individual variations, is usually shorter in cases showing the greatest galvanic reactions, and averages 2.87 seconds. The time required for the curve to reach its maximum height corresponds roughly to the height, a curve of 54 mm. requiring 11.5 seconds and one of 10 mm. requiring 2.5 seconds. The average time is 6.93 seconds.

1201] The inspirations show individual differences in rate and amplitude, and the respiratory rate does not vary as much as the height of the galvanometric curve, as the following table shows:

Height of Galv. Curve	*Inspir. before Stim.*	*Rise of Galv. Curve*	*Fall of Galv. Curve*
54. mm.	3.5 per cm.	3.86 per cm.	3.92 per cm.
18.8 mm.	3. per cm.	2.72 per cm.	2.5 per cm.
4.6 mm.	3. per cm.	2.5 per cm.	2.3 per cm.

1202] Thus the change in rate for a galvanic curve of 54 mm. is not as great as for a curve of 4.6 mm. Whether the respiration is slowed down or speeded up during the rise of the galvanic curve seems to depend on the individual. The majority, however, show a decrease of speed during the rise and an increase during the fall of the galvanic curve.

1203] The average number of inspirations before the stimulus is 3.05 per cm., during the rise of the galvanic curve 3.02 cm., and during the fall 3.09 per cm.

1204] The amplitude of the inspirations does not vary in proportion to the rate. Before the stimulus the average height of the inspirations is 11.75 mm., during the rise of the galvanic curve 10.73 mm., and during the fall of the curve 11.45 mm.

1205] *Part III* (spontaneous speaking). In this part the average height of the galvanic curve is lower than in the preceding part, being 17.9 mm. As a rule the curves of the different subjects show little variation in height. Some of the curves show irregularities before the moment of speaking, caused partly by indecision and partly by preparation for speaking. In normal subjects the galvanic curve begins to rise at the moment of speaking or even a little before.

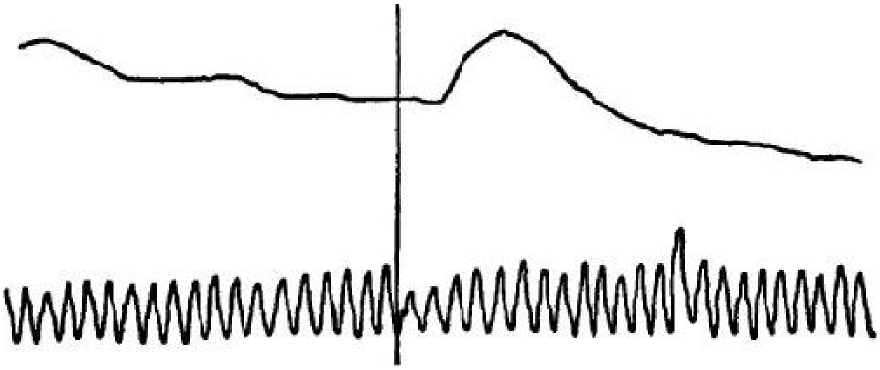

FIG. 1. *Stimulus a falling weight*. Resistance was very high at the beginning of the experiment and fell throughout the quiet period and up to the moment of stimulation, as shown by the vertical line. The latency time and the decrease in rate and amplitude of respirations are clearly shown

1206] *The* number of inspirations per centimetre decreases during the rise of the galvanic curve and continues to decrease as the curve falls. The average rate before speaking is 3.5 per cm., during the rise of the galvanic curve 3.15 per cm., and during the fall 3.04 per cm. The average height of the inspirations before speaking is 10.08 mm., during the rise of the curve 10.57 mm., and during the fall 11.75 mm. Thus the height increases as the rate decreases.

1207] In *Part IV* there are three stimuli: a falling weight, a whistle, and a picture. In each case the stimulus is not merely a sensory, visual, or auditory one, but has also a psychological component. Almost every stimulus, when perceived or received into consciousness, is associated with affective complexes. A low whistle is heard not only as a sound but also as a call, and is associated with many past experiences; a picture calls up many other associations. Naturally the personal equation comes into play here to a very great extent.

1208] The measurements are:

	Weight	*Whistle*	*Picture*
Height of curve	17.94 mm.	18.2 mm.	19.72 mm.
Latency time	2.55 sec.	2.82 sec.	3.03 sec.
Time to reach top of curve[5]	6.95 sec.	9.88 sec.	7.47 sec.

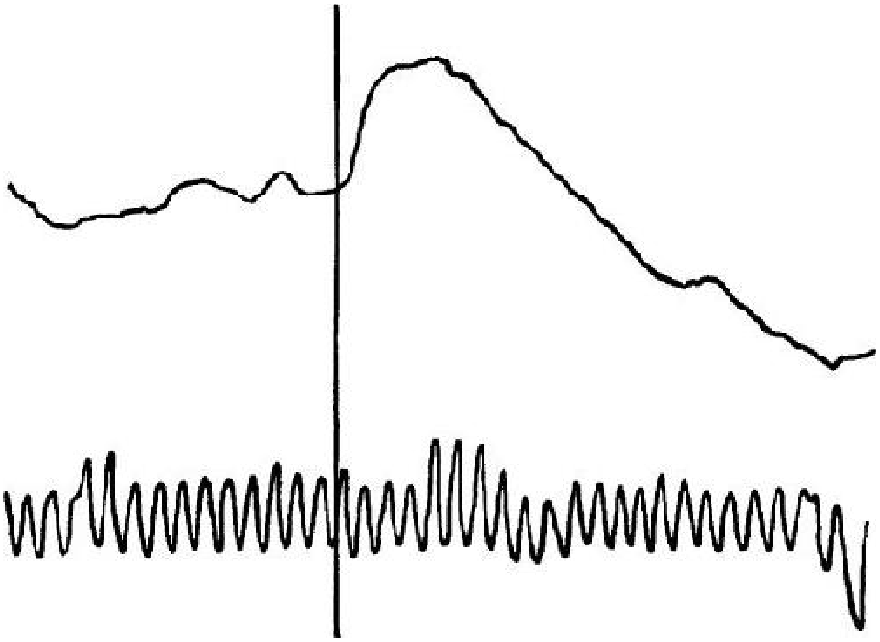

FIG. 2. *Spontaneous speaking*. The vertical line indicates the moment of speaking. The irregularities before speaking are clearly shown in the galvanometric curve. In the respiratory curve the decrease in amplitude during the rise of the galvanometric curve is clearly shown

In these cases the latency time increases with the height of the galvanometric curve. The time for the curve to reach its maximum varies in the different cases.

1209] In every case the respiratory rate increases during the rise of the galvanic curve; in one case it decreases and in two increases during the fall. The amplitude of the respirations varies in the same way, being lower during the rise and increasing in height as the affect passes off. Expressed in tabulated form, the measurements are:

	Inspirations per cm.			*Height in mm.*		
	Weight	*Whistle*	*Picture*	*Weight*	*Whistle*	*Picture*
Before stimulus	3.01	2.75	2.88	12.02	12.05	12.46
Rise of curve	3.33	2.77	3.02	10.56	11.35	10.90
Fall of curve[6]	2.76	3.06	3.09	12.32	12.13	11.33

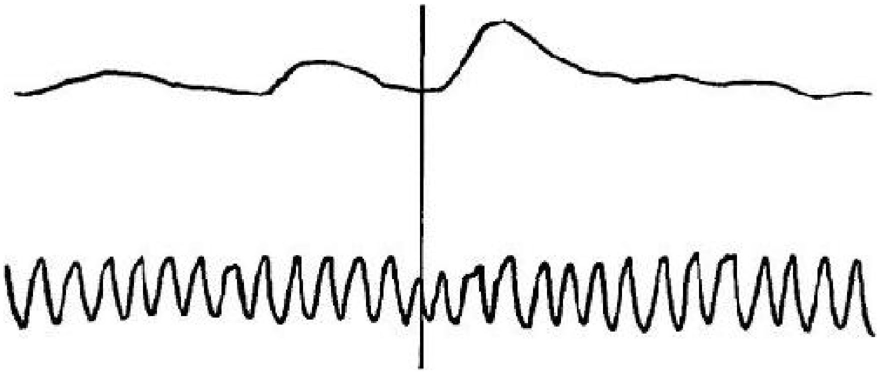

FIG. 3. *Stimulus a whistle*. A small expectation curve, before the movement of stimulus, is shown. The latency period, and the changes in the respiratory rate and amplitude, are clearly shown

1210] *Part V*. Four short sentences or words were used as stimuli. The sentences were spoken by the investigator, and time was allowed between each for the galvanic curve to return to its lowest level. The measurements are:

	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
Height	14.62 mm.	14.48 mm.	19.42 mm.	11.12 mm.
Latency	3.32 sec.	3.1 sec.	2.83 sec.	3.15 sec.
Time to top	8.13 sec.	5.82 sec.	7.67 sec.	5.95 sec.

As can be seen from the table, the height of the galvanic curve gradually decreases in the second and fourth sentences, while the curve of the third sentence is higher. The gradual decrease in the height of the galvanic curve is to be expected and can be explained by the gradual fading out of the affect. The first two sentences were trite, but the third usually referred to the subject or could be referred by him to himself, hence the stronger innervation and the increase in the height of the galvanic curve.

1211] The latency time and the time required for the curve to reach its maximum height bear no constant relation to the height of the galvanic curve.

1212] The respiratory curves vary greatly for the different sentences. In response to two sentences the respiratory rate decreases and in two it increases during the rise of the galvanic curve. The amplitude of the inspirations is always lower while the galvanic curve is rising and while the affect is acting, and slowly increases as the affect wears off, as the following table shows:

	Inspirations per cm.				*Height in mm.*			
	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*	*Sen. 1*	*Sen. 2*	*Sen. 3*	*Sen. 4*
Before	2.84	2.97	2.71	3.05	12.85	12.59	13.74	12.23
Rise	3.04	2.78	2.57	3.41	11.63	11.27	12.81	11.76
Fall	3.09	2.74	3.13	3.46	12.13	11.98	13.38	13.07

1213] *Part VI* is a second quiet period of four minutes. As a general rule this part shows fewer irregularities than the first, because the subject has become accustomed to the experiment and is comfortably settled in his place. One marked feature of this part is the change of level of the respiratory curve as soon as the subject is told that the experiment is over and he is released from the involuntary tension in which he has been held.

1214] The respiratory rate is slower than in the first quiet period. At the beginning the inspirations are 2.41 per cm. as compared to 2.91 per cm. in the first curve. At the end they are 2.71 per cm. as compared to 2.79 per cm. in the first curve. The height of the inspirations is 12.57 mm. at the beginning as compared to 12.41 in the first curve, and 12.17 mm. at the end as compared to 12.26 mm. in the first curve.

1215] What we have designated expectation curves are changes in the galvanic curve that occur while the subject is waiting for the stimulus. Naturally they vary according to the individual. Some of our subjects showed no trace of an expectation curve, whereas in others we found quite marked expectation curves. These curves are more frequent in the early part of the experiment and are especially marked in Part II while the subject is waiting for the fall of the weight. In height they vary with the reactions to the stimuli but are nearly always lower than these.

1216] The average height of expectation curves is 15.70 mm. This high average is due to the fact that a subject who has an intense galvanic reaction to a stimulus will have many and strong expectation curves. The time required for the curve to reach its maximum averages 10 seconds; to fall to the former level, 12 seconds.

1217] The inspirations from the beginning to the top of the curve average 3.06 per cm.; during the fall they average 3.3 per cm. The average respiratory amplitude during the rise is 10.18 mm.: during the fall, 10.56 mm.

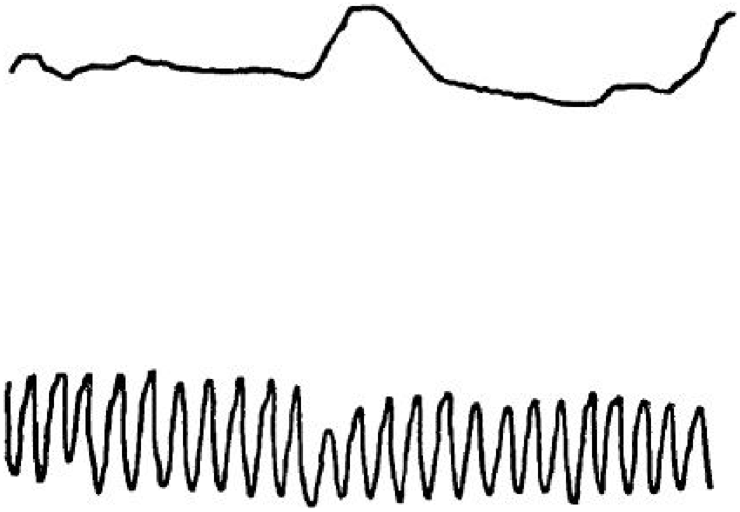

FIG. 4. *Expectation curve*. Showing changes in electrical resistance and respiration due to anticipatory attention

1218] That there are great individual differences in the galvanic reactions will be seen from the average of distribution of the various averages, expressed as a coefficient obtained by taking the average of the sum of the differences between each figure and the average of all the figures.

Part II:	weight	8.09
Part IV:	weight	8.71
	whistle	2.75
	picture	6.64
Part V:	sentence 1	4.7
	sentence 2	4.42
	sentence 3	7.63
	sentence 4	3.98

1219] This coefficient shows, when large, that there is a great diversity in the numbers of which an average is taken; when low, that the numbers are nearly equal. Two of our subjects had extremely high galvanic curves, and therefore the average and coefficient are greater than they would have been had these two cases been omitted. On this account, our averages are probably higher than those of other observers.

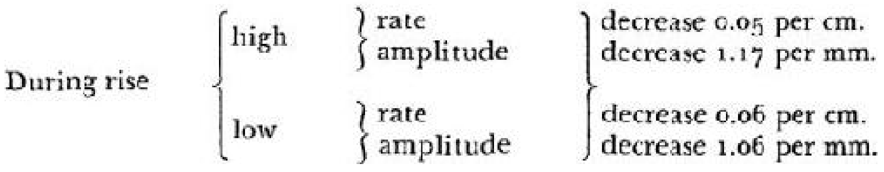
1220] The pneumographic results are interesting because they differ from those obtained by other investigators and because they show a different relation between the rate and amplitude from what one would expect.

1221] The following table shows the averages of all the averages of respiratory rate and amplitude and the average of distribution of each.

	Inspir. per cm.	*Coefficient*	*Height in mm.*	*Coefficient*
Before	2.94	0.16	12.19	0.62
Rise	2.97	0.19	11.28	0.50
Fall	3.11	0.13	12.19	0.47

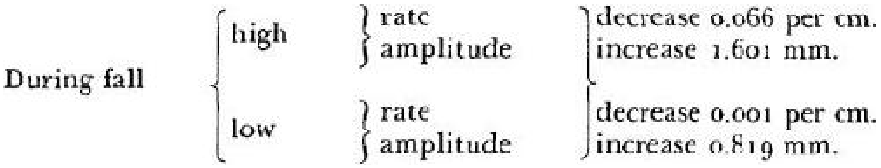
1222] It can be seen that the respiratory rate increases from the moment of stimulus while the amplitude decreases during the action of the affect and increases when it passes away. The coefficients in all cases are low and show that the numbers of which an average was taken are about equal.

1223] The relation between the respiratory rate and amplitude during the rise and fall of the galvanic curve and the high and low galvanic reactions is interesting. These relations were obtained by taking the averages of the sums of the respiratory rates and amplitudes of the high and low reactions of each individual before and after the stimulus. They are:



During rise	high	rate	decrease 0.05 per cm.
		amplitude	decrease 1.17 per mm.
	low	rate	decrease 0.06 per cm.
		amplitude	decrease 1.06 per mm.

1224] Thus during the rise the decrease in rate is practically the same in both high and low reactions but the decrease in amplitude is greater in the higher reactions.



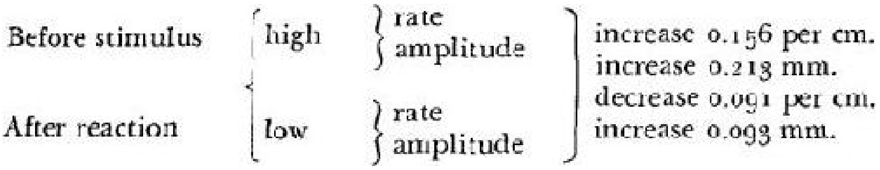
During fall	high	rate	decrease 0.066 per cm.
		amplitude	increase 1.601 mm.
	low	rate	decrease 0.001 per cm.
		amplitude	increase 0.819 mm.

1225] During the fall of the galvanic curve the rate decreases more in the greater than in the lesser reactions, while the amplitude also increases more in the greater than in the lesser reactions.

1226] During the rise of the curve it is probable that part of the bodily innervation is expended on the various affective muscular tensions, etc., and consequently the more the individual reacts with other innervations the less will be expended on the respiration. This would explain the decrease in rate and amplitude in the greater reactions. During the fall of the galvanic curve more innervation is probably concentrated again on the respiration but chiefly on the depth; the rate decreases in some of the greater reactions.

1227] The relations of the rate and amplitude before and after the reaction show that there is an increase in the rate and amplitude after high reactions and a decrease in the rate and increase in the amplitude after low reactions.

1228] The following table was obtained by comparing the rate and amplitude before stimulus with the rate and amplitude during the rise of the galvanic curve, and the rate and amplitude during the fall of the galvanic curve with those occurring during the rise of the galvanic curve.



Before stimulus	high	rate	increase 0.156 per cm.
		amplitude	increase 0.213 mm.
After reaction	low	rate	decrease 0.091 per cm.
		amplitude	increase 0.093 mm.

This table shows that the differences in respiratory changes are much greater in cases of higher galvanic reactions.

1229] So far as could be determined there was no regular relation between the height of the galvanic reactions and the individual bodily resistance at the beginning of the experiment.

ABNORMAL SUBJECTS

1230] These subjects were patients suffering from epilepsy, dementia praecox, general paralysis, chronic alcoholism, and alcoholic dementia and senile dementia.

1231] The conditions of the experiment were exactly the same as in the case of normal subjects except that in many cases the pneumograph could not be used.

Epilepsy

1232] There were nine subjects in this group, the majority being seriously demented. Among these were included one case of traumatic epilepsy with congenital imbecility and one case of epilepsy with hysteria. One subject was examined immediately after an attack of *petit mal*. In this case the reactions to ordinary stimuli were slight or nil, but when the patient was threatened with a needle there was a galvanometric deflection of 20 mm. This change was very slow and the curve remained high for several minutes. The threat of a prick of a needle is a very strong stimulus and causes reactions in nearly every case where dementia is not marked. In this case the whistle produced a fluctuation of 4 mm. and the weight one of 2.8 mm. The other stimuli were without effect. The latency time for the whistle was 5 seconds and for the needle 15 seconds. It required 21 seconds for the curve produced by the needle to reach its maximum.

1233] In this group the differences between the reactions to physical and to psychological stimuli are more marked than in normal subjects. In all cases the quiet period shows little change. Only one subject shows what could be considered an expectation curve.

1234] Five subjects reacted to the falling weight, Part II. The reactions vary from 3.2 mm. to 35.6 mm. The greatest reaction was in the case of epilepsy and hysteria. The three cases not reacting were severely demented. The averages for the cases reacting are:

Height	7.5 mm.
Latency	2.25 sec.
Time to top	6.00 sec.

1235] The pneumographic measurements are:

	Inspirations per cm.	*Average height in n*
Before	2.6	12.28
Rise	2.6	9.73
Fall	2.71	10.81

1236] The galvanometric reaction is only about one-third as high as the normal. The pneumographic measurements are almost the same as those of the normal cases.

1237] Spontaneous speaking (Part III) could only be tried in three cases. In these cases there was a latency time averaging 2 seconds, in contrast to the normal cases where the curve begins to rise at the moment of speaking. The measurements for the three cases are:

Height	14.66 mm.
Latency	2.0 sec.
Time to top	5.5 sec.

1238] These measurements are lower than in normal subjects. The pneumographic results are:

	Inspirations per cm.	*Average height in mm.*
Before	3.5	10.92
Rise	3.3	11.52
Fall	2.9	13.62

In normal cases the amplitude decreases from the moment of stimulus; here it increases.

1239] Part IV, three physical stimuli, weight, whistle, and picture, failed to cause any reaction in three demented cases.

1240] The measurements for five cases are:

	Weight	*Whistle*	*Picture*
Height	26.6 mm.	23.6 mm.	15.4 mm.
Latency	2.3 sec.	3.5 sec.	2.83 sec.
Time to top	6.6 sec.	6.75 sec.	5.3 sec.

1241] In the normal cases the greatest reaction was to the picture. The weight, the stimulus calling up the fewest associations, caused the smallest reaction. The pneumographic measurements in three cases are as follows:

	Inspirations per cm.			*Average height in mm.*		
	Weight	*Whistle*	*Picture*	*Weight*	*Whistle*	*Picture*
Before	2.8	3.0	2.7	8.05	8.23	8.34
Rise	2.5	2.96	3.6	7.1	9.37	6.51
Fall	3.11	3.1	2.9	6.74	8.38	8.03

1242] In the normal cases the height is always less during the rise of the galvanic curve, here it varies very much.

1243] Part V, sentences, caused comparatively slight reactions in all cases. In four demented cases there were no reactions. The measurements for four cases are:

	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
Height	13.4 mm.	7.8 mm.	4.5 mm.	4.5 mm
Latency	3.0 sec.	3.3 sec.	5.0 sec.	3.0 sec.
Time to top	3.6 sec.	5.0 sec.	5.0 sec.	2.0 sec.

1244] The reactions decrease in intensity from the first to the third sentence. The pneumographic curves give the following measurements:

Inspirations per cm.

	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
Before	3.5	3.0	3.0	4.0
Rise	4.0	3.0	3.0	3.0
Fall	3.1	3.3	3.3	2.5

Average height in mm.

	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
Before	7.2	6.7	5.6	7.0
Rise	6.1	7.5	6.0	5.5
Fall	6.8	6.0	6.6	5.5

1245] Part VI, the second quiet period, shows nothing.

1246] In all these cases of varying degrees of dementia the galvanic fluctuations were in direct relation to the degree of mental dullness, seriously demented cases having little or no reaction. In such seriously demented cases the reactions are similar to those of the subject cited above, tested after an attack of *petit mal:* only those stimuli tending to cause pain are reacted to. The problem of this phenomenon is entirely a question of lack of associations.

Dementia Praecox

1247] The cases in this group were in various stages of the disease. The reactions therefore vary considerably. Each form of the disease will be discussed separately.

Catatonia

1248] There were eleven cases of catatonia varying from those in complete stupor to those in a convalescent condition. Our results are high because one convalescent gave reactions that were those of a normal person. Cases in a condition of stupor give practically no reaction to ordinary stimuli; for cases in a depressive state the reaction is also less marked.

1249] The curve for the quiet period varies according to the condition of the subject. In patients who are actively hallucinated it is very often quite irregular; in patients in a stuporous condition it is very nearly a straight line.

1250] The pneumograph was not used.

1251] Part II (falling weight) caused a reaction in almost every case, the reaction varying from 1.8 mm. in a very depressed patient to 6 mm. in a patient with active hallucinations and 43.2 mm. in a convalescent. The average deflection for eleven cases was 6.8 mm.

1252] Part III (spontaneous speaking) was not possible with these subjects.

1253] Part IV (three physical stimuli) caused various reactions, as in normal cases. In five cases of patients in a stuporous, depressed condition, the whistle caused no reaction.

1254] The weight caused a deflection of 6.3 mm., the whistle 2.4 mm., and the picture 3.9 mm. As in the groups of epileptics the weight caused the greatest reactions.

1255] Part IV (four sentences) in every case gave smaller reactions than the physical stimuli. The subject who reacted to the weight with 43.2 mm. reacted to the sentences with a deflection of from 6 to 14 mm. The averages for the four sentences are:

Sentence 1	2.01 mm.
Sentence 2	2.3 mm.
Sentence 3	2.6 mm.
Sentence 4	1.9 mm.

1256] The second quiet period curve shows nothing.

Hebephrenia

1257] There were eleven subjects suffering from this form of the disease. The measurements, while not markedly different from those of the former group, are quite different from the normal.

1258] As in the former group, the quiet curve is irregular whenever the patient has marked hallucinations.

1259] The weight (Part II) caused a weaker reaction than in the former group, the average deflection being 5 mm.

1260] Spontaneous speaking (Part III) in four cases gave an average deflection of 2.6 mm.

1261] The three physical stimuli (Part IV) caused the following reactions: weight, 6.8 mm.; whistle, 3.5 mm.; picture, 4.4 mm. As in the former groups, the weight caused the greatest reaction.

1262] Part V (sentences) caused a greater reaction here than in the former group but a much smaller average reaction than the physical stimuli. The measurements are:

Sentence 1	2.6 mm.
Sentence 2	1.3 mm.
Sentence 3	3.8 mm.
Sentence 4	4.2 mm.

Paranoid Group

1263] There are four subjects in this group, one in an early stage, two somewhat demented, and one seriously demented. The latter reacted to none of the stimuli. The pneumograph was used in two cases.

1264] The quiet period is almost that of a normal subject.

1265] Part II (falling weight) called forth weaker reactions than those in the two preceding groups, the average being 4.8 mm. The latency time averages 3 sec. and the time required for the curve to reach its maximum 7 sec. The rise and fall of these curves is much slower than in the normal cases. The pneumographic measurements of two cases are:

	Inspirations per cm.	*Average height in mm.*
Before	2.5	13.1
Rise	2.94	8.1
Fall	2.63	11.8

These are very close to the measurements obtained in the normal cases.

1266] Part III (spontaneous speaking) was tried in two cases, giving an average deflection of 4.6 mm. The pneumographic measurements are those of the normal cases:

	Inspirations per cm.	*Average height in mm*
Before	3.2	11.78
Rise	2.92	9.2
Fall	2.52	10.76

1267] Part IV (three physical stimuli) gives measurements similar to those of the normal subjects in that the reaction to the picture is the greatest. The measurements are:

	Weight	*Whistle*	*Picture*
Height	5.8 mm.	5.4 mm.	7.0 mm.
Latency	2.5 sec.	2.0 sec.	2.0 sec.
Time to top	6.0 sec.	6.0 sec.	5.5 sec.

1268] The pneumographic measurements for the depth of inspirations are about those of a normal subject. The rate varies in every case, apparently quite freely.

	Inspirations per cm.			*Average height in mm.*		
	Weight	*Whistle*	*Picture*	*Weight*	*Whistle*	*Picture*
Before	3.0	2.7	3.0	11.90	11.61	16.91
Rise	2.78	3.2	4.0	9.32	9.50	11.25
Fall	2.95	3.16	2.91	12.54	11.53	11.31

1269] Part V. The reactions to the sentences are but little higher than those in the other forms of dementia praecox. The measurements are:

	Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
Height	5.2 mm.	3.2 mm.	2.6 mm.	3.0 mm
Latency	3.0 sec.	5.0 sec.	3.0 sec.	3.0 sec.
Time to top	4.5 sec.	5.0 sec.	2.0 sec.	1.0 sec.

The pneumographic curves for the first two sentences only are given, those of the other two being unusable.

	Inspirations per cm.		*Average height in mm.*	
	Sen. 1	*Sen. 2*	*Sen. 1*	*Sen. 2*
Before	3.2	3.0	12.52	13.58
Rise	3.16	2.99	12.16	12.1
Fall	2.5	2.48	13.0	12.22

1270] The second quiet curve is regular in all cases.

Chronic Alcoholism

1271] There are three cases in this group, confirmed alcoholics, but showing no dementia. The galvanometric measurements only are given. The subjects reacted fairly rapidly, and most of them responded more intensely than normal subjects to all stimuli.

1272] The first quiet period shows nothing.

1273] Part II (falling weight) caused a deflection of 23.3 mm., greater than in any of the other groups.

1274] Part III (spontaneous speaking) caused a deflection of 18.6 mm.

1275] Part IV (three physical stimuli, weight, whistle, and picture) caused the following deflections: weight, 24 mm.; whistle, 24 mm.; picture, 28 mm. These reactions are greater than those of the normal subjects. The relation of the reactions to the various stimuli in these and in normal subjects is almost the same in all cases, that to the picture being the greatest and those to the weight and whistle being very nearly the same.

1276] Part V (the four sentences) caused reactions generally greater than in the normal cases, being: Sen. 1, 8.6 mm.; Sen. 2, 16 mm.; Sen. 3, 20 mm.; Sen. 4, 14 mm.

Alcoholic Dementia

1277] There were three cases of alcoholic dementia, which may be contrasted with the last group. In this group the reactions are all weaker than in the cases without dementia, and the smaller reactions to psychological stimuli are especially striking.

1278] The weight caused a deflection of 9.06 mm., as compared to 23.3 mm. for the last group.

1279] Spontaneous speaking caused a reaction of 6.8 mm.

1280] The reactions to the three physical stimuli, weight, whistle, and picture, are very interesting. The picture caused a deflection of only 7.6 mm., as compared to the weight, 16 mm., and the whistle, 13 mm. The reactions are directly proportional to the physical nature of the stimuli. The picture, which in normal cases caused the greatest number of associations and the greatest affects, here caused the fewest associations and the slightest reactions.

1281] The reduction of the reactions to mental stimuli is again seen in the sentences, where they are slight.

Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
3.3 mm.	1.3 mm.	5.6 mm.	2.5 mm.

The reduction here is proportionally much greater than in any of the other groups.

General Paralysis

1282] Nine cases of general paralysis were examined. Two were in a condition of euphoria and one in a period of remission. The other six cases were in a condition of dementia and apathy and gave hardly any reactions to the various stimuli.

1283] The quiet period shows nothing at all for the cases of dementia; in the other cases a few irregularities can be seen.

1284] Part II (the falling weight) caused strong reactions in the two euphoric cases and the case in remission, but no reaction at all in the demented cases.

Height	21.1 mm.
Latency	2.2 sec.
Time to top	6.6 sec.

1285] The pneumographic measurements in these cases are nearly normal.

	Inspirations per cm.	*Average heig*
Before	3.25	8.7
Rise	3.1	7.2
Fall	3.4	9.6

1286] The pneumographic measurements for two cases giving no galvanic reactions are:

	Inspirations per cm.	*Average heig*

Before stimulus	2.5	21.37
After stimulus	3.0	22.3

1287] Spontaneous speaking could not be attempted.

1288] Part IV (three physical stimuli) in the three cases caused the following reactions:

	Weight	*Whistle*	*Picture*
Height	9.4 mm.	25.8 mm.	15.05 mm.
Latency	2.5 sec.	2.3 sec.	2.6 sec.
Time to top	4.0 sec.	7.0 sec.	4.1 sec.

1289] The high average reaction to the whistle is due to the reaction of the patient in a period of remission whose reaction was 70 mm. It will be observed that the weight in these cases caused the smallest reaction. The pneumographic measurements for the three cases are:

	Inspirations per cm.			*Average height in mm.*		
	Weight	*Whistle*	*Picture*	*Weight*	*Whistle*	*Picture*
Before	3.0	3.0	3.65	5.5	5.5	7.9
Rise	3.0	3.0	3.2	4.5	9.1	7.9
Fall	3.0	2.9	3.5	4.8	8.8	7.8

1290] In the case of two patients giving no galvanic reaction the pneumographic measurements are:

	Inspirations per cm.			*Average height in mm.*		
	Weight	*Whistle*	*Picture*	*Weight*	*Whistle*	*Picture*
Before	2.0	3.0	2.0	20.5	20.45	18.5
After	2.0	2.5	2.0	21.12	20.50	19.0

1291] Part V. The results for three sentences are given. Four subjects reacted to these stimuli.

	Sen. 1	*Sen. 2*	*Sen. 3*
Height	16 mm.	9.58 mm.	18 mm.
Latency	4 sec.	2.5 sec.	1.5 sec.
Time to top	5 sec.	4.7 sec.	5.5 sec.

1292] These reactions are nearly the same as those of the normal subjects. The pneumographic measurements for these cases are:

		Inspirations per cm.			*Average height in mm.*	
Before	3.5	3.0	3.0	7.4	7.1	10.
Rise	4.0	3.3	3.3	10.0	8.6	9.0
Fall	4.0	4.6	4.5	11.0	8.1	9.2

1293] The pneumographic measurements of two cases giving no galvanic reaction are:

	Inspirations per cm.		*Average height in mm.*	
	Sen. 1	*Sen. 2*	*Sen. 1*	*Sen. 2*
Before	2.75	3.0	20.75	20.40
After	2.75	2.75	21.30	21.50

1294] Paretics in a condition of euphoria and in a stage of remission, when dementia is not pronounced, react well to the various stimuli. They take a very active interest in the experiment and this may account for the fairly large galvanic reaction. Paretics in a demented condition give no reactions to simple stimuli and correspond to other cases of dementia.

Senile Dementia

1295] There were eleven cases of senile dementia. Most of these cases did not react to the stimuli. In some cases even the prick of a needle caused no galvanic fluctuation.

1296] The weight caused a reaction in three cases. The average deviation for the three cases was 5 mm.

1297] Spontaneous speaking (Part III of the experiment) could not be attempted on account of the dementia.

1298] The three stimuli (Part IV) gave smaller measurements than those obtained in any other disease, the weight causing an average deflection of 1 mm., the whistle 1.8 mm., and the picture 4 mm. The relatively high reaction caused by the picture is interesting.

1299] The mental stimuli, sentences (Part V), caused very little reaction.

Sen. 1	*Sen. 2*	*Sen. 3*	*Sen. 4*
0.6 mm.	0.6 mm.	0.2 mm.	0.8 mm.

1300] The following table gives a survey of the galvanic measurements in mm. of all the subjects:

	Weight	*Spont.*	*Weight*	*Whistle*	*Picture*	*Sentences*			
						1	*2*	*3*	*4*
Normal	20.6	17.9	17.94	18.2	19.72	14.62	14.48	19.42	11.12
Epilepsy	7.5	14.66	26.6	23.6	15.4	13.4	7.8	4.5	4.5
Catatonia	6.8	—	6.3	2.4	3.9	2.01	2.3	2.6	1.9
Hebephrenia	5.0	2.6	6.8	3.5	4.4	2.6	1.3	3.8	4.2
Paranoid D. P.	4.8	4.6	5.8	5.4	7.0	5.2	3.2	2.6	3.0
Chronic alcoholism	23.3	13.6	24.0	24.0	28.0	8.6	16.0	20.0	14.0
Alcoholic dementia	9.06	6.8	16.0	13.0	7.6	3.3	1.3	5.6	2.5
General paralysis: euphoria and remission	21.1	—	9.4	25.8	15.05	16.0	9.58	18.0	—
General paralysis: dementia	—	—	—	—	—	—	—	—	—
Senile dementia	5.0	—	1.0	1.8	4.0	0.6	0.6	0.2	0.8

1301] This table shows that in every case the physical stimuli cause a smaller galvanic fluctuation than the psychological ones, but in the cases where intellectual deterioration is marked the reduction is proportionally greater than in the other cases.

1302] The intensity of the reaction seems to depend partly on the attention paid by the subject to the experiment. In cases of dementia praecox, where internal complexes dominate the affectivity and attention, the reactions are slight; in alcoholism and in general paralysis, euphoric state, where excitability is very great, the reactions are correspondingly greater. In organic dementia, where all associative power is lost, the reactions are almost nil. In dementia senilis, where dementia was very marked, even the prick of a needle failed to cause any response.

1303] The pneumographic measurements in these cases are nearly the same as those found in normal cases. There is evidently no rule for the rate but the amplitude usually decreases while the galvanic phenomenon persists.

1304] That the galvanic fluctuation is caused by the psychological[7] and not the physical factor of a stimulus is shown by the following facts:

1305] The reaction is greatest when the stimulus is such as to call up a large number of associations, e.g., the picture.

1306] A stimulus causing doubt and perplexity is accompanied by a marked galvanic fluctuation, e.g., where the stimulus is a simple word.

1307] In cases of dementia, where associations are few, the reactions are correspondingly weaker.

1308] The physical intensity of a stimulus does not bear any regular relation to the force of the galvanic reaction.

1309] The strength of the reaction changes exclusively according to psychological constellations. This is beautifully shown in one normal case where an ordinary whistle caused only a slight reaction, but the whistle-call of a society to which the subject had belonged as a schoolboy caused a very great fluctuation.

1310] If the attention is not directed to the stimulus the reaction is small or nil. We therefore have no reactions in cases where attention is seriously disturbed. This can be proved by letting the subject count or draw lines on a paper at the beat of a metronome. In this case the reactions are almost nil.

SUMMARY

1311] From the above experiments we conclude that:

(1) The galvanic reaction depends on attention to the stimulus and the ability to associate it with other previous occurrences. This association may be conscious but is usually unconscious.[8]

(2) In our experiments greater galvanic fluctuations are caused, as a rule, by physical than by psychological stimuli. This may be due to the fact that they occurred before the psychological stimuli, early stimuli nearly always causing greater reactions than later ones.

(3) While normal reactions vary greatly in different individuals, they are nearly always greater than pathological reactions.

(4) In depression and stupor, galvanic reactions are low because attention is poor and associations are inhibited.

(5) In alcoholism and in the euphoric stage of general paralysis, reactions are high because of greater excitability.

(6) In dementia, reactions are practically nil because of the lack of associations.

(7) Reactions show great individual variation and within certain rather wide limits are entirely independent of the original bodily resistance.

The pneumographic measurements may be summarized as follows:

(1) The inspiratory rate varies according to the individual and no general rule can be given.

(2) The amplitude of the inspirations generally decreases during the rise of the galvanic curve.

(3) This decrease in amplitude, however, has no relation to the height of the galvanic curve but varies according to individuals.

(4) In cases of dementia where there is no galvanic reaction, changes of respiration exist but are very slight.

APPENDIX

1

STATISTICAL DETAILS OF ENLISTMENT[1]

[1312] As a member of a medical board I had the opportunity last autumn to make a few observations that may be of interest to some of my colleagues and stimulate them to make similar investigations.

[1313] The enlistment at which I was present took place in Lucerne and its environs. The first day of the enlistment produced much strikingly inferior human material. At least, that is how it struck me—it was the first time I had taken part in an enlistment. If I remember rightly, not even half of the recruits were fit. Later on it became even worse. There are places where not even 30 per cent of the male population are fit; it must be emphasized that these places are not industrial towns, but villages in rich and fertile country. The impression that the first day of enlistment made on me, namely the fact that so many mentally inferior men came for examination, induced me to note how many manifestly imbecile men had presented themselves. Since a somewhat too biassed judgment regarding the diagnosis of mental deficiency is attributed to the psychiatrist, I noted only those cases that had also immediately struck the psychiatric layman as idiots. I omitted a number of cases where, after a short examination,[2] I was convinced that I was faced with mental deficiency, in which, however, imbecility was not immediately apparent to the layman. The material under examination consisted of 506 men, of whom 47 (that is, as much as 9.2 per cent) were patently imbecile! 211 men from the town presented themselves; of these 5.6 per cent were imbecile. 232[3] men came from the country; of these 13 per cent were imbecile. The big difference between town and country might be explained by the fact that it is mainly the intelligent and enterprising people who converge on the towns, while the unintelligent and torpid remain in the country. The difference between town and country probably does not mean more than a symptom of the present tendency to migrate into the towns. The imbecility of my cases was so obvious that, where there had been any question of criminal offences, the psychiatrist present had stated that the accused were not responsible for their actions. Should my figures be confirmed throughout, then approximately 9 per cent of Swiss adolescents would not be responsible for their actions! This is a terrifyingly high figure which casts a curious light on the level of intelligence of our people, particularly of the rural population. The even higher figures for physical unfitness raise the question of whether there has always been an inferiority of this kind or whether we are faced with degeneration. In any case, an investigation of this problem in connection with enlistment would, for various theoretical and economic reasons, be worthwhile.

[1314] In this connection one should consider the fact that, in the enlistment district about which I am reporting, the farmers are alleged to have the curious custom of delivering all their milk to the cheese-factories and of feeding their children on coffee and brandy (a similar custom is reported from the canton of Bern).

[1315] When examining those conscripts who reported some ailment to the Commission, I was struck by the large number of alcoholics. To avoid misunderstandings, I noted only those cases that also impressed my colleagues as alcoholics. I therefore included only the cases that revealed themselves as chronic alcoholics through tremor, heart or liver symptoms, and perhaps through signs of polyneuritis. My material comprises 78 men, nearly all of them between the ages of 20 and 30. Of these, 10 (that is 12.9 per cent) had to be discharged as unfit for military service owing to chronic alcoholism. No statistical survey, however, reports this figure because these people are not classified under the heading of alcoholism; they are entered under the more decent title of the alcoholic sequela—for instance, dilatation of the heart or hypertrophy of the heart, chronic gastric catarrh, chronic nephritis, etc. One refers to these alcoholics with a kind of euphemism that certainly often originates in commendable personal consideration but which ultimately leads to a highly detrimental obscuring of the fact that our army annually loses a disproportionately large number of strong men because of alcoholism. What makes matters even worse is the fact that it is the most vigorous age-group that is in question and not the older age-groups. One wonders what conditions are like in the militia if we get such figures for the regular recruits!

2

NEW ASPECTS OF CRIMINAL PSYCHOLOGY[1]

Contribution to the Method Used for the Psychological Diagnosis of Evidence (Tatbestandsdiagnose)[2]

[1316] The very simple experiment designed to induce an individual to respond to a given stimulus-word with the first word that crosses his mind has become the point of departure of a long series of psychological problems that are of interest not only to the psychologist but also to the jurist and the psychiatrist.

[1317] It is not my intention to give here a review of all association experiments; I only wish to indicate one of the possible applications of these experiments, which may interest practical psychologists and criminologists. This is the so-called “diagnosis of evidence” (*Tatbestandsdiagnose*), i.e., the psychological diagnosis of a crime.[3] This term is somewhat pretentious; in practice, those in favour of the method content themselves with more modest results than the infallible diagnosis of a crime. Notwithstanding this limitation, there are some, and they are not a few, who deny any value to the use of the experiment and who maintain that it is without any interest: but as so often, this exaggeration only shows how one falls from one extreme into the other. On the one hand, workers in this field dare not hope that they can arrive at a psychological procedure that will permit them to make a sure diagnosis after only a few preliminary investigations. Medicine, however, possesses quite a number of such methods that have won acceptance only after a laborious struggle. In the field of psychology progress cannot be made any more easily. On the other hand, one must recognize the facile opposition that is based on initial failure of the method; some, like Heilbronner, deny that any application of the experiment can be of value. So the opposition degenerates into a scepticism that arises not from knowledge and serious criticism, but from a deplorably superficial judgment.[4]

[1318] The problem of the diagnosis of evidence is at present of the greatest importance to psychologists; to criminologists it is only of academic interest, since we are still far from its practical application in court: this must be the honest and fair appreciation of the experiments we are going to report.

[1319] The technique is very simple. Let us take an example: a bag containing jewellery, such as a gold bracelet with blue stones, a diamond brooch in the shape of a butterfly, a ring shaped like a snake, and a brooch in the form of a lizard with emerald eyes, was stolen from a hotel. There were also a green leather wallet containing a cheque drawn on the Banca Commerciale Italiana and three banknotes of fifty lire each, and a bottle of Odol.

[1320] The hotel porter and two other employees were suspected of the theft and arrested. Apart from the hotel proprietor, only the culprit could have known the contents of the bag. Such a state of affairs lends itself admirably to the association experiment. Here are examples of the words chosen for it: *gold, fifty, three, bracelet, blue, bank, snake, stone, diamond, lizard, green, leather, butterfly, wallet, cheque, banknote, Odol*, etc. These were distributed among approximately twice the number of other words, chosen for having the smallest possible reference to the evidence. This was done because we wanted to demonstrate how words derived from the evidence, which is known in its minutest particulars only to the culprit, affect people subjected to the experiment.

[1321] How then, generally speaking, do the stimulus-words "act"?

[1322] Needless to say, the subject must consent to the experiment and must obey the instructions. Without his co-operation one cannot, of course, achieve anything. The instruction usually given is this: "You must say, as quickly as possible, the first word that the stimulus-word suggests to you." It is possible for the subject to cheat by not saying the first word that comes to his mind, but in order to reveal the deception, we measure the reaction-time with a stop-watch. If the subject does not say the first word that occurs to him, it is tantamount to rejecting it and he has to look for another; this needs a certain time, which is measurable. A long reaction-time should therefore not mislead the experimenter. The subject of the experiment may well go to the trouble of prolonging his other reaction-times nearly to the same extent, whether they belong to critical words or to others without special meaning. But this deception is as a rule easily seen through since it is known that the reaction-time in educated people is about 1.5 seconds and in uneducated people 2.0 seconds; on the other hand, as the subject deliberately influences the reaction-times, these are as a rule unduly prolonged because it is difficult consciously to judge the lapse of time. Apart from these possible deceptions, every other effect of the critical stimulus-words will result from a disturbance of *attention*. This disturbance arises from the fact that the critical stimulus-word brings back to the mind a content with a strong feeling-tone; this attracts the attention and captivates it for a moment, producing a slowing down of the reaction if a familiar word does not at once present itself. The reproduction method[5] also brings into relief another fact, namely, that reactions to critical words (i.e., those words that revive contents of consciousness with a strong feeling-tone) are more easily forgotten than reactions to words without special meaning. Reactions that immediately follow critical reactions are also often forgotten (perseveration of the disturbance of attention). Why they are so easily forgotten has not yet been sufficiently explored; nor do I wish to enter into any theoretical speculations.

[1323] It often happens that the subject is startled by the critical stimulus-word. This is another disturbing factor, which first affects the reaction-time and then the verbal form of the reaction itself: the subject believes that he has not properly understood or has really misunderstood, or he mechanically repeats the stimulus-word. As, in his embarrassment, he cannot find a word of no special significance, he replaces it with a phrase (and this is against the rules) and then, in uttering this phrase, makes a mistake. In these short moments, which are of immense intrinsic value, he produces many blunders that betray him, such as we all, in our daily lives, also commit for the same reasons, even though as a rule unconsciously. In one case, a student who took part in the experiment, and who was usually very much in command of himself, betrayed himself by making at each critical word a certain small gesture of the hand which he omitted when the word had no special meaning for him.

[1324] All these small disturbing elements in the experiment I have termed "complex-characteristics" (*Complexmerkmale);* this means that they are pointers revealing the influence of a complex of ideas with a particular feeling-tone.[6] These are the complex-characteristics in question:

1. Prolonged reaction-time[7] in the critical reaction or in the one immediately following.

2. Reaction with two or more words, although the subject usually reacts with one word only, according to the instructions.

3. Repetition of the stimulus-word.

4. The stimulus-word (especially the one following the critical word) is misunderstood.

5. Failure to react (i.e., where the subject does not know how to react).

6. *Lapsus linguae* when pronouncing the reaction-word.

7. Translation of the stimulus-word, or of the reaction, into a foreign language.

8. Reaction in the form of an unusual expression.

9. The reaction has a singular content or may be meaningless.

10. Perseveration of the reaction-word in respect of content and of form.

11. Interpolation of "yes" or of other interjections before or after the reaction-word.

[1325] Characteristics 8, 9, and 10 are somewhat arbitrary and can therefore be omitted in an exact computation.

[1326] It may be objected that these deviations cannot with certainty be reduced to psychological disturbances determined by ideas with a special feeling-tone (complexes). This does not in fact appear when the association experiment is used specifically for what we have called the diagnosis of evidence, whereas it becomes quite clear in the case of the accurate analytical examination of the experiments made without a diagnostic purpose. These findings receive considerable support from measuring oscillations of body-resistance to the galvanic current during the association experiment.[8]

[1327] Now, given that these deviations are caused by critical stimulus-words, we may justifiably admit that we are faced with a disturbing inner factor, i.e., an idea with a strong feeling-tone. If, then, with a particular subject these deviations occur mainly in connection with critical reactions—i.e., in response to stimulus-words derived from actuality—then we can confidently assume that with the word that influences the subject a complex is operative that refers to actual facts. This complex may embrace simply the subject’s general knowledge about a particular crime; should stimulus-words refer to this crime then a certain emotion is bound to arise in response to every one of these stimulus-words. But it may also turn out that the disturbing complex is one that points to a feeling of guilt in the subject.

[1328] An innocent suspect, as well as a guilty one, will of course show a certain emotion in response to critical stimulus-words. We do not yet know whether this emotion exerts the same perturbing influence over each of them, or whether the reaction of the innocent can be qualitatively distinguished from that of the guilty; only further experience can decide this question.

[1329] In the case of our hypothetical crime only the guilty party knows the details of the facts, whereas innocent suspects hardly know the general outline. From the experiment it appears that all the critical stimulus-words have a disturbing effect on the porter, whereas in the other two employees most of the critical reactions are quite normal. From this we may conclude that suspicion must very probably fall on the porter and that his guilt appears to be established; moreover, the complex-characteristics are, significantly enough, recognized through those stimulus-words the importance of which cannot by any means be known to the innocent.

[1330] We have no absolute proof of guilt, but it is clear that in such cases the experiment may provide valuable pointers for further investigation. This will happen especially when there is a large number of suspects and when the elements of suspicion about some of them lack a solid basis; in such a case we can, with the help of the experiment, eventually succeed in tracing those on whom graver suspicion must fall. Let us, however, repeat that the results of the experiment will not provide absolute proof of guilt but, at best, merely a valuable addition to the circumstantial evidence. If one has to do with only one suspect and if there are no facts with which to confront this person, then the results are unquestionably most unreliable.

[1331] Some two years ago I published a case from my practice, in which a thief confessed his crime as a result of strong evidence arising from the association experiment.[9] A short time ago I was concerned with another case of theft that from the technical point of view lent itself very well to the experiment; like the first case, it was entirely successful.[10]

. . . .

Critique and Qualitative Analysis

[1332] Faced with these results, the reader who is without a thorough knowledge of the method is bound to ask himself this question: Is it not possible that one of the three suspects who was not the subject of this research would, on examination, present an even greater number of signs of guilt? This is of course *a priori* possible, but in practice one always begins with the subject to whom the evidence points most clearly; in our case this was definitely the nurse A. From this reasoning my concept of the experiment clearly emerges: it should only, in the first place, show us which of the subjects presents the maximum number of complex-disturbances. Then we have the suspect who shows himself most disturbed, either because he is really the culprit or because the fear of appearing guilty causes great agitation. Nurse B appeared very agitated during the experiment and this prejudiced me against her, even though she did not show distinct signs of a guilt-complex. Nurse C was relatively calm but nevertheless the complex-characteristics were more numerous. This discrepancy needs to be examined further. Why do the innocent usually show signs of a guilt-complex? The answer to this question presents no difficulties. Nurse B knew all the particulars of the case and during the experiment Nurse C had an inkling of its importance. It is therefore easy to understand why words like *theft, to steal,* and *police* created in them an unpleasant feeling that in its turn produced the characteristic disturbance of the experiment. Here we have the explanation of why even the innocent can show a not inconsiderable number of signs of guilt-complex. What distinguishes them from the guilty are not (at least as far as we know at present) qualitative differences but mainly quantitative ones.

[1333] It is nevertheless surprising that Nurse B, who had been given exact information about the circumstances of the theft and who was evidently affected by strong emotion, showed fewer signs of guilt-complex than Nurse C, who was the calmer of the two. Only psychoanalysis, applied to each association, can throw light on this question.

[1334] In Nurse C the words *watch, chain, silver*, produced evident complex-disturbances; now, by an unfortunate coincidence, both the watch and the chain had been broken a few days before. The word *to hide* also has a disturbing influence; Nurse C had a short time before taken away her evening meal and hidden it, something that was absolutely forbidden in the hospital. *Fear, to discover, innocent, suspect, to lie* are all disturbing words: it was known that through negligence she had mislaid or lost a garment belonging to one of the patients. It suddenly occurred to her during the experiment that this incident was being enquired into, since nothing had so far been discovered about it; and that was why signs of guilt-complex appeared in response to these words.

[1335] The interference of other individual complexes seriously compromised the results of the investigation but this was unavoidable. One of the few measures that could be taken to this end would be to use a long series of stimulus-words (100—200) of which as many as possible would refer to definite details of the case and would be of similar categories since, if they were, they would produce disturbances owing to the intellectual work involved. *A priori* one would regard as most suitable words that are apparently of no special significance and that yet have a special significance in relation to the case (the so-called "exchange" [German, *Wechsel*], according to Freud's apt expression[11]).

[1336] Let us therefore try to assess the importance of words that have a direct reference to the case as compared with those that have only a general connection with the theft.

[1337] First we shall again calculate the probable mean of the reaction-times; we shall, however, reduce the numbers of B and C as if the reaction-times of these subjects had the same general probable mean as those shown by A (11.0).

Probable Mean of Reaction-times
(reduced to the level of that of the culprit)

	A	B	C
Special stimulus-words	15	15.1	12.2
General stimulus-words	18	11.0	14.6

[1338] We can see that the general stimulus-words have a very strong influence on the guilty nurse A. The special stimulus-words have the same effect on the guilty A and on the innocent B, whereas on B the general stimulus-words show very little effect. In this case the expected confirmation was not forthcoming.

[1339] Let us now investigate the same question from the point of view of complex-characteristics.

Average Number of Complex-characteristics per Reaction

	A	B	C
Special stimulus-words	1.2	0.9	1.0
General stimulus-words	1.5	0.7	1.1

[1340] We find here in essence a state of affairs similar to that in the reaction-times, i.e., [in the case of A and C][12] the general stimulus-words exercise a stronger influence.

[1341] Let us now examine the disturbances of reproduction from the same point of view.

Incorrect Reproductions

	A	B	C
Special stimulus-words	0.4	0.2	0.2
General stimulus-words	0.6	0.2	0.3

[1342] This shows that the figures for disturbances of reproduction are larger for the general stimulus-words [for A and C].

[1343] Little can be expected, for the time being, from the study of such associations as follow immediately upon critical associations; this is because we do not know when, in what individuals, or in what complexes a particularly strong perseveration may exert a disturbing influence on the experiment. One could presume that perseveration would appear mainly after very intense emotion, but it is not at all certain that this would be shown by the experiment. Should it prove to be true, it could turn out to be one of the origins of disturbance associated with perseveration. Another cause may be found in the fact that quite often the total range of the preceding stimulus-word is not readily understood, so that soon enough other ideas suddenly appear, not infrequently carrying strong feeling-tone. But all these contingencies demand very accurate investigations. Until these are completed, we shall not be able to benefit from whatever emerges from the research—according to which, words referring in a special way to the evidence leave in their train more disturbances in the post-critical associations than general stimulus-words do.

[1344] The most intense after-effect was produced in the culprit by the following stimulus-words; I give the reactions with the ordinary reactions that follow them.

Stimulus-word		*Reaction*	*Reaction-time*	*Reproduction*[13]
(1) banknote		money	15	–
mountain	r	to climb	26	–
to play		to sing	15	–
(2) suspect (noun)		nobody	43	+
bottle		water	17	–
fire		wood	9	–
(3) to hide		to lose, to look for	18	–
sofa		seat	17	–
night		day	6	+
(4) chain		round the neck	19	–
(5) silver		gold	10	+
(6) money	r	centime	34	–
wine		beer	8	+

(7) open	r	free	6	+
(8) key		keyhole	19	+
house		courtyard	13	–
lamp		light	8	+

[1345] Just as we have found that it is *on the whole* the general stimulus-words that work with the utmost intensity, so we now see that the strongest single impact is made by those stimulus-words that refer particularly to the evidence. This shows that the general stimulus-words usually have a strong effect, whereas the special stimulus-words sometimes have an intense effect and sometimes a weak one.

[1346] The only way in which we can do full justice to these results is to apply them as much as possible to practical cases since, for reasons not far to seek, laboratory investigations are always rather incomplete.

[1347] I am confident that with this work I have awakened a certain interest in experiments of this kind and have encouraged others to follow in this direction. It is only by the work of many, directed always towards the examination of practical cases, that we can hope to make the diagnosis of a particular case a matter of greater certainty.

3 THE PSYCHOLOGICAL METHODS OF INVESTIGATION USED IN THE PSYCHIATRIC CLINIC OF THE UNIVERSITY OF ZURICH[1]

[1348] 1. Rapidity of apperception: short exposure of simple pictures.

2. Working through psychological material and fidelity of reproduction: retelling of three fables. The first fable contains two similar simple situations which, however, differ from each other by one important nuance. The second fable is similar but more complicated. The third fable is in principle similar, but contains a whole series of similar situations.

3. Fatiguability of the will: Kraepelin’s method of reckoning.

4. Emotionally charged contents (“complexes”): Jung’s association method.

5. Psychogenic mechanism and symptom-determination: Freud’s psychoanalytic method.

4 ON THE DOCTRINE OF COMPLEXES[1]

[1349] It is difficult to express in a short summary the doctrines laid down in my two books, “Diagnostic Association Studies” and “The Psychology of Dementia Praecox.” What I state here must necessarily be incomplete and superficial.

[1350] My theoretical views on the neuroses and certain psychoses—especially dementia praecox—are founded upon the psychological outcome of the *association experiment*. These experiments are used for the demonstration of certain intellectual types, but I must here mention that an important point was formerly disregarded, namely, the disturbing influence of the experiment on the subject. Thus, in my practice of using a series of *stimulus-words*, and allowing the subject to react to them, that is to give answers to each word, the reactions often do not come with equal smoothness, but very irregularly, or with lengthened intervals; or there appear other disturbances such as repetitions of the stimulus-word, slips of the tongue, several reaction-words instead of one, etc. These irregularities were formerly regarded as mere faults of the experiment, and not taken into further consideration. In collaboration with Riklin, however, I have now given special attention to these disturbances. Noting at which stimulus-words they occur, we find that it is principally where a stimulus-word refers to a personal matter, which, as a rule, is of a distressing nature. Often the relation between the two is not clear at first glance, but is rather of a “symbolic” character, it is in fact an “allusion.” Usually there are only a few personal matters to which the disturbances of the experiment refer. Riklin and myself have introduced for this “personal matter” the term *complex*, because such a “personal matter” is always a collection of various ideas, held together by an emotional tone common to all. With practice and experience one may easily attain the faculty of collecting those stimulus-words which will most likely be accompanied by disturbances, then of combining their meanings and deducing therefrom the intimate affairs of the subject. It is obvious that this procedure is of special importance in a psychological examination of patients. (It is important also to note the use of the procedure in criminology; I, myself, have detected by its means two cases of theft.) Here I must mention that nearly all the German authorities have pronounced against the method, but its use is generally recognized in Switzerland and in the United States of America. French and English psychiatrists are as yet unfamiliar with the method.

[1351] The experiment, which I perform usually with a hundred specially selected and collocated stimulus-words, serves as an indication of the psychic contents of a patient and his mode of reaction. This is of special importance with regard to the neuroses, the psychic origin of which present-day observers no longer doubt. Somatic states are never the real, but only the predisposing causes of the neuroses. The neurosis itself is of psychic origin, and emanates from "special psychic contents," which we call a *complex*. It has been discovered that the complexes revealed by association experiment are either pathogenic conflicts or at least nearly such, so that by association experiment the pathogenic complex is easily located. If one wishes to penetrate still further into the psychological connections of a neurosis, one must have knowledge of Freud's psychoanalytic method. But for a superficial grasp of the psychic contents of a neurosis the association experiment is quite sufficient. It is interesting to find that the experiment discloses thought-complexes, which were not mentioned at all in the history of the case. The obvious reason for this is the distressing character of the complexes. At the outset, patients do not talk to the doctor quite frankly about more private matters, and it is precisely these matters which have the most important bearing on the genesis of the neurosis. That these painful private matters are mostly conflicts of a distinctly psychosexual nature is to the unprejudiced judge of human nature a matter of course. Occasionally the psychosexual conflict is very deeply hidden, and can be discovered only by psychoanalysis. In many cases the aroused complex is by no means approved by the patient, who even tries in every way to deny, or at least to weaken, the existence of the complex. Since it is therapeutically important to induce the patient to self-recognition, i.e., to a recognition of his "repressed" complexes, one must take this fact into careful consideration, and proceed with corresponding care and tact.

[1352] The association experiment provides the means of studying experimentally the behaviour of the complex. Experience teaches us the close relation between complex and neurosis. We must assume that the complex is a thought material, which stands under special psychological conditions, because it can exert a pathogenic influence. In the association experiment we first observe that it is the intention of the subject to react quickly and correctly. This intention is disturbed by the interference of the complex, so that the association, contrary to expectation, is either turned from the sense of the complex or replaced by fragmentary allusions, or is in general so disturbed as to render the subject altogether unable to produce a reaction, although he may be unaware that the complex is independent of his intentions. The same observation is confirmed by applying the so-called *reproduction method*. If after the finished association experiment we let the subject repeat all the reactions to the different stimulus-words, we find the uncertainty of recollection (the so-called faulty reproduction) usually at those places where the complexes have interfered (though we must not lose sight of the perseveration factor of the complex). Therefore, the "faulty reproduction" is also to be regarded as a sign of the complex, and this is theoretically interesting because it shows that even the moods associated with a complex are subject to certain exceptional conditions, that is, they are inclined to be quickly forgotten or replaced. The uncertainty of the subject towards the complex-associations is characteristic; they are to the individual either of an obsession-like stability, or they disappear totally from the memory, and may even cause false memories—as may be well observed *in nuce* during the experiment. This points also to the complex and its association material having a remarkable independence in the hierarchy of the psyche, so that one may compare the complex to revolting vassals in an empire. Researches have shown that this independence is based upon an intense emotional tone, that is upon the value of the affective elements of the complex, because the "affect" occupies in the constitution of the psyche a very independent place, and may easily break through the self-control and self-intention of the individual. The "affect-intensity" of the complex can be easily proven psychophysically. For this property of the complex I have introduced the term *autonomy*. I conceive the complex to be a collection of imaginings, which, in consequence of this autonomy, is relatively independent of the central control of the consciousness, and at any moment liable to bend or cross the intentions of the individual. In so far as the meaning of the ego is psychologically nothing but a complex of imaginings held together and fixed by the coenesthetic impressions, also since its intentions or innervations are *eo ipso* stronger than those of the secondary complex (for they are disturbed by them), the complex of the ego may well be set parallel with and compared to the secondary autonomous complex. This comparison shows the existence of a certain psychological similarity, because the emotional tone of the secondary complexes is also based upon coenesthetic impressions, and, further, both the ego and secondary complex may be temporarily split up or repressed, a phenomenon which may be observed with particular clearness in hysterical delirium and other "cleavages" of personality. Especially in those states where the complex temporarily replaces the ego, we see that a strong complex possesses all the characteristics of a separate personality. We are, therefore, justified in regarding a complex as somewhat like a small secondary mind, which deliberately (though unknown to consciousness) drives at certain intentions which are contrary to the conscious intentions of the individual. Hysterical symptoms are the products of those counter-endeavours; they originate from the complex, and are all the more intense and obstinate the greater the autonomy of the complex is. I may say here that the superstition held by all races that hysterical and insane persons are "possessed" by demons is right in conception. These patients have, in fact, autonomous complexes, which at times completely destroy the self-control. The superstition is therefore justified, inasmuch as it denotes "possession," because the complexes behave quite independently of the ego, and force upon it a quasi-foreign will.

[1353] By means of the association experiment, aided by Freud's psychoanalytic method, I have succeeded in proving that all neuroses contain autonomous complexes, whose disturbing influences have a disease-producing effect. Amongst the psychoses, Kraepelin's dementia praecox has undoubtedly proved itself a "complex disease," at least in its initial stages. (I regard the noted but still unconfirmed anatomical alterations as secondary.) In this disease the autonomy of the complexes may sometimes be observed with surprising distinctness; for instance, the overpowering force of "voices," the obsessions arising from catatonic impulses, etc.

[1354] The objection that neuroses and dementia praecox are totally different affections, and cannot possibly be founded upon the same disturbances, I can only meet here with the suggestion that more or less autonomous complexes occur everywhere, even in so-called normals. The question is, to what extent are the complexes really autonomous, and in what form does the reaction take place? The researches of Freud and his school have shown how hysteria reactively deals with the complexes, while the work of the Zurich school has shown a characteristic and different behaviour of dementia praecox; with this, however, I cannot deal here at length. I may say only that certainly in both the neuroses and dementia praecox the symptoms—whether of a somatic or of a psychic nature—originate from the complex as has been described in detail by the school of Freud. While in hysteria there occurs usually a continuous accommodation to the surroundings, in consequence of which the complexes are subjected to continual alterations, in dementia praecox on the contrary the complexes are fixed, so that they usually arrest the progress of the general personality; this we call dementia. In estimating the extent of this dementia some authors have gone much too far in assuming that the repulsive and degenerate exterior of the patient is the result of an equally great interior decay. This is quite incorrect, because the patients still possess a very vivid life of fantasy, of which, however, they are able only in exceptional cases to give utterance. In these fantasies, of which in some instances the patients are quite unconscious, they deal with the fixed complex in a way which is intensely interesting to the observer. In fact, this is the workshop where delusions, hallucinations, etc., are produced from really sensible connections. The direction of thought is, however, entirely turned away from reality, and prefers thought-forms and material no longer of interest to modern man; hence many of these fantasies appear in a purely mythological garb. Owing to the loss of the recent biological train of suitable thought, there is apparently substituted an antiquated form. (I may refer here to a similar conception of the hysterical symptom by Claparède and Janet.)

[1355] In this short summary I have been forced to restrict myself entirely to indications and assertions. Proofs have not been offered, because the subject has already reached the extent of a special science, a science which may be called "Analytical Psychology,"[2] or after Bleuler, "Deep Psychology" ("Tiefenpsychologie").

[1356] In conclusion, I would draw attention to the following publications. An account of all works on association methods will be found in:

Jung. *Diagnostische Associationsstudien*. Band I and II. J. A. Barth, Leipzig.[3]

A summary of these methods in the English language appeared in *Lectures and Addresses delivered before the Departments of Psychology and Pedagogy*, in celebration of the 20th anniversary of the opening of Clark University, Sept., 1909, Worcester, Mass., 1910.[4]

These lectures contain an account of the practical application of the experiments in a case of theft.

Further details may be found in:[5]

Jung. *Die psychologische Diagnose des Tatbestandes*.

5 ON THE PSYCHOLOGICAL DIAGNOSIS OF EVIDENCE[1]

The Evidence-Experiment in the Näf Trial

The method of investigating crime called "psychological diagnosis of evidence" was thought out and first published thirty years ago in the *Archiv für Kriminologie*, vol. XV, pp. 72–113.

In that paper, entitled "Psychological Diagnosis of Evidence: ideas on psychological experimental methods of ascertaining whether or not a person had taken part in a particular crime," all that is essential in the method and its technique was described and can be referred to there.[2]

[1357] In a letter of October 31, 1934, the Criminal Court of Canton Zurich, in the case of Hans Näf, dental technician of Mogelsberg, asked for an opinion on the following question: "Would the interrogation of the accused by me reveal anything that would be of considerable significance for the judge who has to decide on the guilt or innocence of the accused?"

[1358] For my information, copies of the following documents were handed to me:

1. A graphological opinion given by Dr. Pulver on March 21, 1934.
2. Psychiatric opinion of the director of the Canton Asylum, Burghölzli, of August 10, 1934.
3. The act of indictment from the Police Court, Zurich.

[1359] A further basis for my opinion was the result of a so-called "evidence-experiment."

I. THE EXPERIMENT

[1360] Since the expert opinion of the psychiatrist had already established the mental state and the character of the subject, I was concerned only with a psychological examination of the accused with regard to a possible guilt- or innocence-complex. Such an examination is called the evidence-experiment. In principle it consists in an association experiment distinguished from the usual form, in which stimulus-words are used without any ulterior motive, in that so-called critical stimulus-words taken from the evidence are interspersed with the others. In the case under consideration a list of 407 stimulus-words was used. (The experiment took more than three hours.) Of these 407 words, 271 were neutral, 96 referred to the evidence, and 40 were of an emotional nature and referred to the history and conditions of life of the subject.

[1361] Examples of evidence-words: *murder, death, to die, gas, suicide, rubber tubing, morphia, advantage, fraud, to rub out, letter, table, floor, accident, to marry, bottle, syringe, beer, ampoule,* etc.

[1362] Examples of emotional stimulus-words: *theft, Stolp,*[3] *girl, to despise, to despair, peace, anxiety, unjust,* etc.

[1363] Experience has shown that stimulus-words referring to very emotionally charged contents of consciousness cause considerable disturbances in reaction; i.e., the subject cannot comply with the instruction to respond as quickly as possible to the stimulus-word with the word that immediately comes to his mind. The usual disturbances, which in technical language are called complex-characteristics, are these:

1. A reaction-time longer than the average (measured with a stop-watch).

2. Repetition of the stimulus-word by the subject (as if he had not heard it properly).

3. Mishearing of the stimulus-word.

4. Expressive movements (laughing, twitching of the face, etc.).

5. Reaction with more than one word.

6. Strikingly superficial reaction (purely mechanical, according to sound, etc.).

7. Meaningless reaction.

8. “Failure” (failing to give a reaction).

9. Perseveration, i.e., a disturbing influence on subsequent reactions.

10. Defective reproduction (i.e., after the experiment we try to find out whether the subject remembers the reactions he gave the first time).

11. Slips of the tongue (stammering, etc.).

[1364] To this list should be added the use of foreign words; this happens in 27 out of 34 cases (i.e., approximately 80 per cent of the cases) with critical words. In the case under observation we very often observed a slight movement of the left index-finger; this happened with 81 per cent of the critical stimulus-words and is therefore regarded as a complex-characteristic.

[1365] The exact observation, measurement, and recording of the complex-characteristics thus served the purpose of ascertaining emotionally charged contents as well as of establishing their character.

II. THE RESULTS OF THE EXPERIMENT

1. *The Reaction-time*

[1366] Stimulus-words that had no personal meaning, excluding those that immediately followed a critical stimulus-word and therefore were disturbed through perseveration of the affect, resulted in a mean reaction-time of 2.4 seconds.

[1367] Stimulus-words referring to the evidence had to be divided into two groups according to their reaction-time; namely, those with a long and those with a short reaction-time. In the latter group we usually found a perseveration-phenomenon which made itself noticeable by a prolonged reaction-time of the association immediately following. When the reaction-time of a critical association was long, then the reaction-time of the following association without personal meaning was short; i.e., it equalled the mean of the reactions without personal meaning. When the reaction-time of the critical association was short, then the following one was long. This resulted in the following picture:

Reaction-time after critical stimulus-word:

First group: long 3.2 secs.
short 2.5 ”
Second group: short 2.4 secs.
long 3.3 ”

[1368] Expressed in words: the evidence-words produce, either directly or indirectly, a reaction-time the mean prolongation of which is 0.8 and 0.9 seconds.

2. *The Complex-characteristics*

[1369] The experiment reveals the following distribution of the complex-characteristics described above:

Associations without personal meaning contain 0.6 complex-characteristics

Evidence stimulus-words contain 2.2 complex-characteristics

Emotional stimulus-words contain 2.0 complex-characteristics

[1370] Stimulus-words that are taken from the evidence produce, it appears, almost four times as many disturbing elements as stimulus-words without personal meaning; the disturbing influence of the former surpasses that of the emotional stimulus-words by 0.2.

3. *Incorrect Reproductions*

[1371] The incorrect reproductions were numbered together with the complex-characteristics. In 31.7 per cent of all reactions the memory failed. No less than 77 per cent of these mistakes occurred in the critical reactions and in those immediately following them (disturbed by perseveration). The memory fails:

In 32.5% of the emotional associations

In 36.0% of the evidence-associations

In 20.5% of the associations without personal meaning (outside the range of perseveration).

Expressed in words: the critical stimulus-words that are taken from the evidence had the greatest disturbing influence on the memory.

4. *Maximally Disturbed Associations*

[1372] Among the 407 associations of the total experiment there are 36 that are maximally disturbed, i.e., that are characterized by four complex-characteristics, or by a particularly long reaction-time, or by strong perseveration. Of these, 29 belong to the evidence stimulus-words and 7 to the emotional stimulus-words. Computed in percentages of the total number (96) of the evidence stimulus-words, there were 30.2 per cent; of the emotional stimulus-words (40), 17.5 per cent. This means that the evidence stimulus-words produced 30.2 per cent maximal disturbances and the emotional stimulus-words only 17.5 per cent. Such stimulus-words as were recognizable beforehand as without personal meaning did not produce any maximal disturbances at all.

[1373] Since the disturbances of the normal experiment always indicated the presence of affective contents (apart from accidental external influences which, however, were absent in this experiment), this rule applies, of course, in great measure to maximal disturbances.

[1374] The following were the maximally disturbed associations:

Stimulus-word	Repetition, Interjection, or Misunderstanding	R.T.[34]	Reaction	Finger-movements	Reproduction	Number of C.C.'s in the critical & post-critical reactions
1. suicide	(yes)	5.0	to make-death	–	–	5/1
2. to die	(sigh)	8.8	death	+	–	5/3
3. stupid	–	6.0	not intelligent	–	–	4/2
4. to scorn	+	9.4	not to love	–	–	4/2
5. smell	–	3.0	notice nothing[4]	+	–	5/3
6. gas	–	3.2	poison methane	+	–	5/5
7. cow	++	6.8	mammal	+	–	5/5
8. drunk	+	5.2	intoxication	–	–	4/2
9. hose	–	2.0	rubber	–	+	1/4
10. month	+	5.8	s'Munots-glöckli,[4] part of the year	–	–	5/1
11. to marry	–	2.6	dear—yes	–	–	4/2
12. truth	–	3.6	is best—yes	–	–	4/2
13. beer	–	6.0	I like it, I dare say[4]	+	–	6/2
14. bottle	–	1.8	wine, beer	–	+	2/6
15. ampoule	–	4.0	adrenalin	+	–	5/2
16. to inherit	–	4.0	disinherited	+	+	5/1
17. intoxication	–	3.0	silly feeling	–	–	4/1
18. inheritance	–	4.0	without—	+	–	5/3
19. marriage	–	10.0	married	–	–	3

20. picture postcard	–	5.2	for sending	+	+	4/2
21. ground	–	3.2	air etc.	–	–	4/2
22. twenty-two	–	3.0	February	–	+	4/2
23. peace	–	3.0	unpeaceful	+	–	4/1
24. brush	+	4.0	to clean	–	+	3/5
25. soap	–	4.0	fatty	–	+	2/4
26. tap	–	2.8	brass	+	+	3/3
27. to despair	+	8.8	don't know	+	–	5
28. *heimlich* (cozy, secret)	–	2.8	*nicht-unheimlich* (not-uncanny)	+	–	4
29. illustrated	–	10.0	don't know what it's called	–	–	5/2
30. anxiety	+	3.6	to press	+	–	4/1
31. calf	+	4.8	cow	+	–	4/1
32. success	–	4.0	unsuccessful	–	–	4/1
33. to kill	–	3.6	how can I express myself?—unpleasant—to suffer	++	+	3/4
34. periodical	+	2.8	subscription	–	+	3/4
35. syringe	–	2.4	for injecting	+	–	4/3
36. injecting	–	3.6	injection	+	–	5/1

[1375] As we have already mentioned, of the 36 stimulus-words 29 are taken from the evidence. Of these, 18 are designations of definite concrete phenomena, namely: *smell*, *gas*, *drink*, *hose*, *beer*, *bottle*, *ampoule*, *intoxication*, *picture postcard*, *ground*, *brush*, *soap*, *tap*, *illustrated*, *to kill*, *periodical*, *syringe*, and *injecting*. These constitute 62.0 per cent of the maximally disturbed evidence-reactions. In the total experiment 96 evidence stimulus-words occur and of these 53.1 per cent designate concrete phenomena. Thus the maximally disturbed reactions occur mainly in response to concrete evidence stimulus-words, and this exceeds the normal expectation by 9 per cent. In other words: it is precisely the concrete details of the evidence that prevail over the more general aspects of the evidence.

[1376] To summarize:

1. The evidence stimulus-words prevail over the emotional stimulus-words by 12.7%.

[3a] [R.T. = reaction-time; C.C. = complex-characteristics.]

[4] [Original in Swiss dialect.]

[5] ["Little Bell-Tower of Munot," Swiss dialect song.]

2. Among the evidence stimulus-words, those prevail that refer to concrete or otherwise distinctive details of the evidence by 9%

5. *The Minimally Disturbed Critical Associations*

[1377] 25 per cent of the evidence stimulus-words and the same percentage of emotional stimulus-words are minimally affected, i.e., less than 2 complex-characteristics. Among them there are stimulus-words of which one would under normal conditions have expected a certain effect; for instance, the wife's Christian name and the following words: *woman, to abort, cocaine, to do in, death, murder, morphia, to rub out, accident, money, poisonous, last will and testament, gaol, punishment, loss, judgment*, etc. To the stimulus-word *total*, the subject reacted with *to kill* after only 2.8 seconds.

[1378] Among the evidence stimulus-words with minimal effect there are 37.5 per cent stimulus-words that refer to concrete content of the evidence, while there are 62.0 per cent among the maximally disturbed ones. This shows that the evidence stimulus-words are distinguished from the other categories by their appreciably stronger effect.

THE EXPERT OPINION

[1379] It must be stated, in the first place, that an association experiment will, under these conditions, result as a rule in appreciably higher degrees of disturbance with critical reactions. The reason is that the critical stimulus-words invariably stir up already-existing affects which in their turn disturb the associations. The general picture of disturbance will therefore not necessarily mean a great deal. It would, however, be a most aggravating piece of circumstantial evidence in the case of a defendant who at the preliminary inquiry had not been made acquainted with the evidence and therefore could not possibly know the details. In our case every detail of the evidence is known, even the incriminating details. Therefore the disturbance of the critical reaction is not relevant in evaluating the psychological situation. So only a consideration of small variations can promise some success. Consequently I devised the experiment in a certain way: I selected general stimulus-words that are assumed to be affectively potent, in order to obtain a yardstick for the general emotional make-up of the subject; then I selected general and special stimulus-words obtained from the evidence, in order to determine whether the general emotional situation or the special concrete evidence is in the foreground of the affective interest.

[1380] Experience has shown that a defendant who is sure of his innocence will concentrate more on the general fact of the injustice of being suspected than on any particular detail of the evidence, which is for him irrelevant. For him it is not the particular concrete details that carry a guilty and therefore confusing affective charge but the stimulus-words referring to the indignation roused by his sense of justice and to his fear of possible conviction. As our findings demonstrate beyond doubt, one subject is much less affected by the general emotional stimulus-words than by those referring to the evidence; among these, the particular concrete details prevail that carry weight for the judicial proof of guilt.

[1381] The reaction to the stimulus-word *brush* was: "I pronounce the word *brush*"; the subject is startled and repeats *brush* as if he had not properly understood the word. Then he hesitates for 4 seconds until he can say *cleaning*. The next stimulus-word, *to force*, which follows immediately, finds him unprepared because his attention is still disturbed by *brush*. So he also repeats this stimulus-word; the reaction takes as much as 6.2 seconds. Contrary to the instructions, which he usually follows, he lapses into dialect.[5] The stimulus-word *soap*, which would in itself be harmless, produces such an after-effect that the subject cannot find any reaction at all to the stimulus-word *important* that follows, although he has a considerable vocabulary and is quite able to react quickly according to his educational standard.

[1382] Such processes are responsible for the disturbances in 62 per cent of the concrete evidence-reactions. From this fact it must be concluded that it is mainly the subject's ideas referring to the concrete details of the evidence that carry the strongest affects, and that other affects recede into the background.

[1383] That this diagnosis is not incorrect is proved by the fact that the subject himself spontaneously states, with every sign of affect, that the maximally disturbed associations to *suicide* and *to die* have touched on his suicidal ideas. Just as his ideas revolve round the theme of suicide, so they move round the concrete details of the evidence. This is statistically corroborated by our findings.

[1384] It must be emphasized that, apart from the suicide-complex, out of four stimulus-words referring to stupidity (*stupid, sheep, cow, calf*) no less than three are maximally disturbed. This fact can only be understood as meaning that the subject experiences a very strong inner conflict because of a piece of stupid behaviour.

[1385] The maximal disturbance at *to marry* and *marriage* indicates complications that can only be interpreted as meaning that his married life was no simple matter but of a problematical character.

[1386] Likewise, the stimulus-words *to inherit* and *inheritance* elicit a maximal disturbance, which proves that these words too point to a background full of conflict and complication.

[1387] The stimulus-words *clandestine* and *truth*, with maximal disturbance, indicate that the subject was not prepared to respond to these ideas.

[1388] To summarize, and in reply to the original question, it must therefore be stated that the subject's psychological situation, as revealed by the experiment, in no way corresponds to what one would empirically expect in an innocent person. To assess the signs of a guilty conscience, however, must be left to the discretion of the judge.

THE COLLECTED WORKS OF

C. G. JUNG

THE PUBLICATION of the first complete edition, in English, of the works of C. G. Jung was undertaken by Routledge and Kegan Paul, Ltd., in England and by Bollingen Foundation in the United States. The American edition is number XX in Bollingen Series, which since 1967 has been published by Princeton University Press. The edition contains revised versions of works previously published, such as *Psychology of the Unconscious*, which is now entitled *Symbols of Transformation;* works originally written in English, such as *Psychology and Religion;* works not previously translated, such as *Aion;* and, in general, new translations of virtually all of Professor Jung's writings. Prior to his death, in 1961, the author supervised the textual revision, which in some cases is extensive. Sir Herbert Read (d. 1968), Dr. Michael Fordham, and Dr. Gerhard Adler compose the Editorial Committee; the translator is R. F. C. Hull (except for Volume 2) and William McGuire is executive editor.

The price of the volumes varies according to size; they are sold separately, and may also be obtained on standing order. Several of the volumes are extensively illustrated. Each volume contains an index and in most a bibliography; the final volume will contain a complete bibliography of Professor Jung's writings and a general index to the entire edition.

In the following list, dates of original publication are given in parentheses (of original composition, in brackets). Multiple dates indicate revisions.

*1. PSYCHIATRIC STUDIES

On the Psychology and Pathology of So-Called Occult Phenomena (1902)

On Hysterical Misreading (1904)

Cryptomnesia (1905)

On Manic Mood Disorder (1903)

A Case of Hysterical Stupor in a Prisoner in Detention (1902)

On Simulated Insanity (1903)

A Medical Opinion on a Case of Simulated Insanity (1904)

A Third and Final Opinion on Two Contradictory Psychiatric Diagnoses (1906)

On the Psychological Diagnosis of Facts (1905)

†2. EXPERIMENTAL RESEARCHES

Translated by Leopold Stein in collaboration with Diana Riviere

STUDIES IN WORD ASSOCIATION (1904–7, 1910)

The Associations of Normal Subjects (by Jung and F. Riklin)

An Analysis of the Associations of an Epileptic

The Reaction-Time Ratio in the Association Experiment

Experimental Observations on the Faculty of Memory

Psychoanalysis and Association Experiments

The Psychological Diagnosis of Evidence

Association, Dream, and Hysterical Symptom

The Psychopathological Significance of the Association Experiment

Disturbances in Reproduction in the Association Experiment

The Association Method

The Family Constellation

PSYCHOPHYSICAL RESEARCHES (1907–8)

On the Psychophysical Relations of the Association Experiment

Psychophysical Investigations with the Galvanometer and Pneumograph in Normal and Insane Individuals (by F. Peterson and Jung)

Further Investigations on the Galvanic Phenomenon and Respiration in Normal and Insane Individuals (by C. Ricksher and Jung)

Appendix: Statistical Details of Enlistment (1906); New Aspects of Criminal Psychology (1908); The Psychological Methods of Investigation Used in the Psychiatric Clinic of the University of Zurich (1910); On the Doctrine of Complexes ([1911] 1913); On the Psychological Diagnosis of Evidence (1937)

*3. THE PSYCHOGENESIS OF MENTAL DISEASE

The Psychology of Dementia Praecox (1907)

The Content of the Psychoses (1908/1914)

On Psychological Understanding (1914)

A Criticism of Bleuler's Theory of Schizophrenic Negativism (1911)

On the Importance of the Unconscious in Psychopathology (1914)

On the Problem of Psychogenesis in Mental Disease (1919)

Mental Disease and the Psyche (1928)

On the Psychogenesis of Schizophrenia (1939)

Recent Thoughts on Schizophrenia (1957)

Schizophrenia (1958)

†4. FREUD AND PSYCHOANALYSIS

Freud's Theory of Hysteria: A Reply to Aschaffenburg (1906)

The Freudian Theory of Hysteria (1908)

The Analysis of Dreams (1909)

A Contribution to the Psychology of Rumour (1910-11)

On the Significance of Number Dreams (1910-11)

Morton Prince, "The Mechanism and Interpretation of Dreams": A Critical Review (1911)

On the Criticism of Psychoanalysis (1910)

Concerning Psychoanalysis (1912)

The Theory of Psychoanalysis (1913)

General Aspects of Psychoanalysis (1913)

Psychoanalysis and Neurosis (1916)

Some Crucial Points in Psychoanalysis: A Correspondence between Dr. Jung and Dr. Loÿ (1914)

Prefaces to “Collected Papers on Analytical Psychology” (1916, 1917)

The Significance of the Father in the Destiny of the Individual (1909/1949)

Introduction to Kranefeldt’s “Secret Ways of the Mind” (1930)

Freud and Jung: Contrasts (1929)

†5. SYMBOLS OF TRANSFORMATION (1911–12/1952)

PART I

Introduction

Two Kinds of Thinking

The Miller Fantasies: Anamnesis

The Hymn of Creation

The Song of the Moth

PART II

Introduction

The Concept of Libido

The Transformation of Libido

The Origin of the Hero

Symbols of the Mother and of Rebirth

The Battle for Deliverance from the Mother

The Dual Mother

The Sacrifice

Epilogue

Appendix: The Miller Fantasies

*6. PSYCHOLOGICAL TYPES (1921)

Introduction

The Problem of Types in the History of Classical and Medieval Thought

Schiller’s Ideas on the Type Problem

The Apollinian and the Dionysian

The Type Problem in Human Character

The Type Problem in Poetry

The Type Problem in Psychopathology

The Type Problem in Aesthetics

The Type Problem in Modern Philosophy

The Type Problem in Biography

General Description of the Types

Definitions

Epilogue

Four Papers on Psychological Typology (1913, 1925, 1931, 1936)

†7. TWO ESSAYS ON ANALYTICAL PSYCHOLOGY

On the Psychology of the Unconscious (1917/1926/1943)

The Relations between the Ego and the Unconscious (1928)

Appendix: New Paths in Psychology (1912); The Structure of the Unconscious (1916) (new versions, with variants, 1966)

‡8. THE STRUCTURE AND DYNAMICS OF THE PSYCHE

On Psychic Energy (1928)

The Transcendent Function ([1916]/1957)

A Review of the Complex Theory (1934)

The Significance of Constitution and Heredity in Psychology (1929)

Psychological Factors Determining Human Behavior (1937)

Instinct and the Unconscious (1919)

The Structure of the Psyche (1927/1931)

On the Nature of the Psyche (1947/1954)

General Aspects of Dream Psychology (1916/1948)
On the Nature of Dreams (1945/1948)
The Psychological Foundations of Belief in Spirits (1920/1948)
Spirit and Life (1926)
Basic Postulates of Analytical Psychology (1931)
Analytical Psychology and *Weltanschauung* (1928/1931)
The Real and the Surreal (1933)
The Stages of Life (1930–1931)
The Soul and Death (1934)
Synchronicity: An Acausal Connecting Principle (1952)
Appendix: On Synchronicity (1951)

*9. PART I. THE ARCHETYPES AND THE COLLECTIVE UNCONSCIOUS

Archetypes of the Collective Unconscious (1934/1954)
The Concept of the Collective Unconscious (1936)
Concerning the Archetypes, with Special Reference to the Anima Concept (1936/1954)
Psychological Aspects of the Mother Archetype (1938/1954)
Concerning Rebirth (1940/1950)
The Psychology of the Child Archetype (1940)
The Psychological Aspects of the Kore (1941)
The Phenomenology of the Spirit in Fairytales (1945/1948)
On the Psychology of the Trickster-Figure (1954)
Conscious, Unconscious, and Individuation (1939)
A Study in the Process of Individuation (1934/1950)
Concerning Mandala Symbolism (1950)
Appendix: Mandalas (1955)

*9. PART II. AION (1951)

RESEARCHES INTO THE PHENOMENOLOGY OF THE SELF

*10. CIVILIZATION IN TRANSITION

Flying Saucers: A Modern Myth (1958)
A Psychological View of Conscience (1958)
Good and Evil in Analytical Psychology (1959)
Introduction to Wolff's "Studies in Jungian Psychology" (1959)
The Swiss Line in the European Spectrum (1928)
Reviews of Keyserling's "America Set Free" (1930) and "La Révolution Mondiale" (1934)
The Complications of American Psychology (1930)
The Dreamlike World of India (1939)
What India Can Teach Us (1939)
Appendix: Documents (1933–1938)

†11. PSYCHOLOGY AND RELIGION: WEST AND EAST

WESTERN RELIGION

Psychology and Religion (The Terry Lectures) (1938/1940)
A Psychological Approach to the Dogma of the Trinity (1942/1948)
Transformation Symbolism in the Mass (1942/1954)
Forewords to White's "God and the Unconscious" and Werblowsky's "Lucifer and Prometheus" (1952)
Brother Klaus (1933)
Psychotherapists or the Clergy (1932)
Psychoanalysis and the Cure of Souls (1928)
Answer to Job (1952)

EASTERN RELIGION

Psychological Commentaries on "The Tibetan Book of the Great Liberation" (1939/1954) and "The Tibetan Book of the Dead" (1935/1953)
Yoga and the West (1936)
Foreword to Suzuki's "Introduction to Zen Buddhism" (1939)
The Psychology of Eastern Meditation (1943)

The Holy Men of India: Introduction to Zimmer's "Der Weg zum Selbst" (1944)

Foreword to the "I Ching" (1950)

*12. PSYCHOLOGY AND ALCHEMY (1944)

Prefatory note to the English Edition ([1951?] added 1967)

Introduction to the Religious and Psychological Problems of Alchemy

Individual Dream Symbolism in Relation to Alchemy (1936)

Religious Ideas in Alchemy (1937)

Epilogue

†13. ALCHEMICAL STUDIES

Commentary on "The Secret of the Golden Flower" (1929)

The Visions of Zosimos (1938/1954)

Paracelsus as a Spiritual Phenomenon (1942)

The Spirit Mercurius (1943/1948)

The Philosophical Tree (1945/1954)

‡14. MYSTERIUM CONIUNCTIONIS (1955–56)

AN INQUIRY INTO THE SEPARATION AND SYNTHESIS OF PSYCHIC OPPOSITES IN ALCHEMY

The Components of the Coniunctio

The Paradoxa

The Personification of the Opposites

Rex and Regina

Adam and Eve

The Conjunction

*15. THE SPIRIT IN MAN, ART, AND LITERATURE

Paracelsus (1929)

Paracelsus the Physician (1941)
Sigmund Freud in His Historical Setting (1932)
In Memory of Sigmund Freud (1939)
Richard Wilhelm: In Memoriam (1930)
On the Relation of Analytical Psychology to Poetry (1922)
Psychology and Literature (1930/1950)
“Ulysses”: A Monologue (1932)
Picasso (1932)

†16. THE PRACTICE OF PSYCHOTHERAPY

GENERAL PROBLEMS OF PSYCHOTHERAPY

Principles of Practical Psychotherapy (1935)
What Is Psychotherapy? (1935)
Some Aspects of Modern Psychotherapy (1930)
The Aims of Psychotherapy (1931)
Problems of Modern Psychotherapy (1929)
Psychotherapy and a Philosophy of Life (1943)
Medicine and Psychotherapy (1945)
Psychotherapy Today (1945)
Fundamental Questions of Psychotherapy (1951)

SPECIFIC PROBLEMS OF PSYCHOTHERAPY

The Therapeutic Value of Abreaction (1921/1928)
The Practical Use of Dream-Analysis (1934)
The Psychology of the Transference (1946)
Appendix: The Realities of Practical Psychotherapy ([1937] added, 1966)

‡17. THE DEVELOPMENT OF PERSONALITY

Psychic Conflicts in a Child (1910/1946)
Introduction to Wickes’s “Analyses der Kinderseele” (1927/1931)

Child Development and Education (1928)
Analytical Psychology and Education: Three Lectures (1926/1946)
The Gifted Child (1943)
The Significance of the Unconscious in Individual Education (1928)
The Development of Personality (1934)
Marriage as a Psychological Relationship (1925)

*18. THE SYMBOLIC LIFE

Miscellaneous Writings

†19. GENERAL BIBLIOGRAPHY OF C. G. JUNG'S WRITINGS

†20. GENERAL INDEX TO THE COLLECTED WORKS

See also:

C. G. JUNG: LETTERS

Selected and edited by Gerhard Adler, in collaboration with Aniela Jaffé Translations from the German by R.F.C. Hull.

VOL. 1: 1906–1950
VOL. 2: 1951–1961

THE FREUD/JUNG LETTERS
Edited by William McGuire, translated by
Ralph Manheim and R.F.C. Hull

C. G. JUNG SPEAKING: Interviews and Encounters
Edited by William McGuire and R.F.C. Hull

C. G. JUNG: Word and Image
Edited by Aniela Jaffé

[1] C. A. Mace, “On the Eightieth Birthday of C. G. Jung,” *Journal of Analytical Psychology*, I:2 (1956).

[2] First published 1968 as *Analytical Psychology: Its Theory and Practice*.

[3] See the bibliography under their respective names. Jung published two abstracts of the Studies: (1) At the request of the French psychologist Alfred Binet, an “analyse bibliographique” of Vol. I of the *Studien* in Binet’s journal, *L’Année psychologique* (Paris), XIV (1908), 453–55; (2) Summaries of both volumes of the *Studien*, in “Referate über psychologische Arbeiten schweizerischer Autoren (bis Ende 1909),” compiled by Jung, in the *Jahrbuch fur psychoanalytische und psychopathologische Forschungen* (Leipzig and Vienna), II (1910),366–74; see Volume 18 of the Collected Works.

[1] [First published as “Experimentelle Untersuchung über Assoziationen Gesunder,” *Journal für Psychologie und Neurologie* (Leipzig), III (1904), 55–83, 145–64, 193–214, 238–308, and IV (1905), 24–67. 109–23. Republished in *Diagnostische Assoziationsstudien: Beiträge zur experimentellen Psychopathologie*, edited by C. G. Jung, Vol. I (Leipzig, 1906; 2nd edn., 1911; 3rd edn., 1915). pp. 7–145 (I. Beitrag). Translated by M. D. Eder in *Studies in Word-Association* (London, 1918; New York, 1919).

[Franz Riklin (1878–1938) was assistant physician on the staff of the Burghölzli at this time. From 1907 to 1913, he and Jung were active in the International Psycho-Analytical Association. For his principal publications, see the Bibliography.]

[2] A later paper will report on time-measurements. The times were not measured in all subjects. [See below, “The Reaction-time Ratio in the Association Experiment.”]

[3] Cordes, “Experimentelle Untersuchung über Assoziationen” (1899), p. 30.

[4] Ibid., p. 33.

[5] Ranschburg states that in uneducated subjects inner associations predominate. With Balint, “Über quantitative und qualitative Veränderungen geistiger Vorgange im hohen Greisenalter” (1900).

[6] Aschaffenburg, too, is cautious about this and confines himself entirely to the relation between stimulus and reaction as it is reflected in speech. He insists on this, since the linguistic reaction does not by any means always tally with the simultaneous inner associations. (“Experimentelle Studien über Assoziation” (1896), p. 220.)

[7] Trautschold says: “First and foremost in this respect is practice or habit, which facilitates certain associations so much that in the end they occur quite mechanically, and there can be no question of other reactions” (“Experimentelle Untersuchungen über die Assoziation der Vorstellungen” (1883), p. 221).

[8] Claparède, *L’Association des idées* (1903), p. 218.

[9] [No such publication has been traced.]

[10] Ziehen *(Introduction to Physiological Psychology* (orig. 1891). p. 205), arguing against internal association, gives as examples the following: *guest/chest, pain/rain*, and remarks that these so-called internal associations are purely external and are almost completely limited to the acoustic image of words that have similar sounds. One can readily agree with Ziehen, for surely no one will want to call these examples of inner association.

We consider, with Wundt, that associative affinity is the principle of internal association and practice the principle of external association (or similarity = internal association, contiguity = outer association).

[19] Experimentelle Untersuchungen über die Assoziation der Vorstellungen," p. 213.

[20] [In German, *Grunad/und Boden* (bottom/and ground), an expression referring to the hospital grounds.]

[21] [In German, *Kind/Kegel* (child/bastard); *Kind und Kegel* is a folk expression for "the whole family."]

[22] [Goethe's dying words.]

[23] [*Matte/Hänge* = *Hängematte*, 'hammock,' originally a hanging mat. Some of these compounds are untranslatable.]

[24] [Referring to someone who is "cold-blooded."]

[25] [The actual example, *Tränensack*, refers to the lacrymal sac.]

[26] [The German, *aufhören*, means to listen attentively.]

[27] [In the German language there is the generic term *Spielball*, meaning a ball used for any game.]

[28] Wreschner, "Eine experimentelle Studie über die Assoziation in einem Falle von Idiotie" (1900), p. 241.

[29] ["Sound" = German *Klang*, also translated in the *Coll. Works* as "clang."]

[30] [The examples given by Jung are *Laufen* (to run)/*burg* and *Winter/thur*, both giving the name of a town.]

[31] [Jung's examples (except for *to roast/roast beef*), being untranslatable, have been replaced by similar pairs of English words.]

[32] [Some of the rhyming pairs have been replaced by English equivalents.]

[33] [Most of the original examples are not translatable, so equivalents have been found.]

[34] [Many of the original examples, being untranslatable, have been replaced by English equivalents.]

[35] Intensity of attention; see above, par. 86.

[36] Münsterberg maintains that, in order to stimulate associations, the external excitation does not first have to be converted into a conscious process, but that, between external excitation and conscious central excitation, there is a non-conscious stage in which an association-process takes place that does not reach consciousness *(Beiträge zur experimentellen Psychologie* IV (1892), p. 7). Nevertheless, Münsterberg denies the occurrences of indirect associations through conscious intermediate links (ibid., p. 9).

[37] “Eine experimentelle Studie über die Assoziation in einem Falle von Idiotie.”

[38] Aschaffenburg’s “association to words previously used.”

[39] We use the word “perseveration,” as in Müller’s and Pilzecker’s experiments [“Experimentelle Beiträge zur Lehre vom Gedächtnis,” 1900], to denote merely the continuance of the preceding image in so far as it is manifest in the following reaction. The term is intended to be purely formal and is not intended to explain anything. We offer no opinion on whether the perseveration is a cortical or a cellular (nutritional) process (Gross) or whether the result is a particular associative constellation. In any case, we wish to stress that our concept has no connection with the “perseveration” in organic cerebral processes any more than with the hypothetical “secondary function of brain cells” which is said to explain the psychological after-effect of the vector-image.

[1] Aschaffenburg says: “Our attention is so enormously unstable, the non-controllable and unavoidable changes in our psychic life so great, that we should not use short experimental series. On the other hand one must not forget that in the course of longer experiments signs of fatigue occur, so that it is not, for example, permissible to compare the first 25 associations with the last 25 of a series of 200 reactions, without taking this fact into consideration” (“Experimentelle Studien.” I, p. 217). Thus Aschaffenburg has noted the same phenomenon, but in our view has not interpreted it correctly.

[2] *Psychol. Arb*., I, p. 53. Kraepelin distinguishes between “lassitude” [*Müdigkeit*] and “fatigue” [*Ermudung*]. Lassitude he regards as a sort of warning, a subjective feeling which, however, usually but not always develops before real fatigue.

[3] Ranschburg and Hajós, *Beiträge zur Psychologic des hysterischen Geisteszustandes* (1897).

[4] Aschaffenburg, I, p. 239. At the time of the formation of the external association linguistic habit predominates, while later, on reflection, a secondary tendency to co-ordinate develops.

[5] “The facilitation of motor-impulses must be considered the essential factor responsible for the number of sound reactions exceeding the norm” (Aschaffenburg, II, p. 69; see also the work of Smith, Fúrer, and Rudin on the effects of alcohol, in Kraepelin’s *Psychol. Arb*.). [For Rüdin, see Bibliography. Smith and Fürer did not contribute to *Psychol. Arb*., though Rudin and others cited their work on this subject.]

[6] The expression “exhaustion” merely denotes a higher degree of impairment of mental and physical energy (Aschaffenburg, II, p. 47),

[7] Heilbronner, “Über epileptische Manie nebst Bemerkungen über die Ideenflucht” (1903).

[8] There are, incidentally, also pure manias which, particularly when subsiding, still show a definite flight of ideas in a completely steady state of motility.

[9] [The reference is to a well-known quotation from Goethe’s *Torquato Tasso,* Act II, Sc. I: “Man merkt die Absicht und man ist verstimmt” (“One notices the intention and becomes out of humour”).]

[10] [In German, a rhyme: *mächtig/prächtig.*]

[11] Aschaffenburg errs when he says, for example, that Nordau’s descriptions referred to hypomanics; they refer rather to the larger group of individuals incapable of concentration and showing blunt association-type.

[12] See below, experiment in drowsiness with subject 15 (educated men).

[13] By that we do not mean that some sort of motor excitation is responsible for the blunt reaction type. In personalities of a motor type the motor factors perhaps play an independent role in the word-image combination in that they facilitate talking.

[14] Cf. subject 16 (educated men).

[15] Cf, subjects 15 and 16 (educated men).

[16] Ranschburg and Balint, p. 689.

[17] In his experiments on normal people Aschaffenburg had only one subject who had a strikingly large number of failures; he was a dreamy, vague, poetic young man (IV, p. 243). [The textual allusion is to “Association, Dream, and Hysterical Symptom,” infra.]

[18] By “emotionally charged complex” we mean the sum of ideas referring to a particular feeling-toned event. We shall always use the term “complex” in this sense in what follows. [In the present volume, “emotionally charged” is the translation adopted for German *affektbetonte* and, as a rule, “feeling-toned” for *gefühlsbetonte*. Cf. vol. 1, par. 168, n. 2a, and vol. 3, “Psychology of Dementia Praecox,” pars. 77 ff. (ch. 2).]

[19] We know, of course, that no reaction is fortuitous, but that each one, even the most objective, is caused by definite constellations. It makes, however, a great difference whether, e.g., *murderer* is associated with *Meier* and thus points to a definite murderer, or *murderer* is associated with *criminal* which expresses a general thought. This difference we stress by using the designation “constellation.”

[20] [*Süsskind*, literally ‘sweet child.’]

[21] See Jung, “On Simulated Insanity.”

[22] [Well-known phrase, *Hangen und Bangen*, from one of Schiller’s poems.]

[23] [Dr. Konrad Alt (1861–1922) was director of a mental hospital at Uchtspringe, Saxony, renowned for its advanced methods. The Säntis and the Altmann are high mountains in northeastern Switzerland.]

[24] [The song “Wir winden dir den Jungfernkranz,” from Weber’s opera *Der Freischütz.*]

[25] [In German, *müssen / “kein Mensch muss müssen.”* The quotation is from Lessing’s *Nathan der Weise.*]

[26] [In the original, he misquotes even this fragment.]

[27] The reactions of this subject are given in detail in the section on Calculations of Averages, Complex-Constellation Type, pars. 429ff.

[28] For technical reasons the experiment with internal distraction could not be carried out with any of the uneducated subjects.

[29] After the breaking off of her romance, her brother was the only person in whom the subject confided.

[30] The braces to the left of the stimulus-words indicate that these immediately succeeded each other.

[31] Reactions of between one and two seconds are considered normal. [All reaction-time data in this paper are in seconds.]

[32] [German *Obst* is the equivalent of English ‘fruit’ in a collective sense. *Frucht* is the term for particular fruit but is also used in the phrase “the fruit of the womb.”]

[33] Cf. “emotional stupidity”: Jung, “On Simulated Insanity.”

[34] See below, Calculations of Averages, par. 405 (6).

[35] The numbers refer to the order of the stimulus-words on the form; they are given only to show at what intervals these repetitions occur.

[36] Liepmann, *Über Ideenflucht, Begriffsbestimmung und psychologische Analyse* (1904).

[37] With the exception, of course, of people with specific dispositions.

[38] By this we mean a difference of attention only in the quantitative sense, not by any means a qualitative difference.

[39] One can say that in general the more uneducated and unintelligent a subject is, the more he interprets the stimulus-word as a question. This is shown most clearly in idiots, who, with few exceptions, always interpret the stimulus-word as a question and then give a definition or an explanation of it in the reaction.

[40] Incidentally, educated subjects have the same experience with words of a language that they have never read in print or writing. When stimulus-words are called out in dialect, the educated subjects sometimes have difficulty in understanding the words, because they are used to hearing dialect words only in a sentence-connection.

[41] We stress here once more that by this classification we intend to mark only the clear and obvious differences in the mode of reaction. We know very well that basically every subject belongs in fact to, for example, the complex-constellation type, as no reaction is fortuitous but irrevocably conditioned by the psychological past of the subject. What we wish to clarify by our classification is the degree of subjective dependence in so far as it is clearly expressed in the reactions.

[42] This not-wanting-to-betray is, as we have become convinced from numerous experiments, by no means always a conscious not-wanting but quite often anunconscious inhibition, which in most cases also causes a lengthening of the reaction-time.

[43] A later paper will report on the variation of the reaction-times. [See infra.]

[44] A subject whose inner life is strongly affected by an unpleasant financial matter reacts within normal time to *ill* with *poor* and in the following reaction, *Stolz* (‘pride’) / *Boh* (‘arrow’), with lengthened reaction-time. For no obvious reason the association is a senseless rhyme. Sound associations and rhymes occur in this subject only at “critical” points. *Poor* has a quite special emotional significance for this subject; attention remains attached to the constellated complex, which results in a disturbance of the succeeding reaction because of internal distraction.

[45] The subject already quoted in the preceding footnote reacts to *pity* with *poor ones (poor* has a particular feeling-tone). The succeeding association is *yellow (gelb) / much*. It is another perseveration of the financial complex, *gelb* being immediately assimilated as *Geld* (money), although the subject has long been familiar with all the stimulus-words on our list.

[46] In some subjects the repetitions also have a certain significance as the indirect expression of the complex. (We have pointed this out several times in the relevant section.) Certain words that are more or less closely associated with the complex, or that indirectly replace it, are frequently repeated.

[47] [*Oven* stands for the German *Ofen*, the German name of Buda, the sister town of Pest (Hungary). *Ofen* really means ‘oven.’]

[48] [Cf. supra, par. 212, n. 15.]

[49] [See n. 47.]

[50] [The German word *Blumenstock* (literally, “flowerstick”) is mainly used for a tree-shaped potted plant such as a fuchsia.]

[51] We note that the description of indirect associations at present deserves no greater value than that of a working hypothesis. We willingly offer our figures and our interpretations for further discussion

in the hope that several research workers in cooperation might succeed in solving this question satisfactorily.

[52] The occurrence of indirect associations under the influence of a distraction of attention has long been known from another source. The tangential naming of pictures in alcoholic delirium (Bonhöffer), in epileptic mania (Heilbronner), in certain catatonic and hysterial conditions, etc., is nothing but indirect association which is formed not, as in our experiment, through shift via sound similarity but through a shift via image similarity. Thus, in this case, it is a supplementary phenomenon of flight of ideas in the visual sphere and corresponds at all points to the phenomena we have shown in the acoustic-verbal sphere. [For Bonhöffer and Heilbronner, see Bibliography.]

[54] H. Piéron, "L'Association médiate" (1903).

[55] [Cf. "The Psychology of Dementia Praecox," par. 110, where the example is given with slight differences.]

[56] Jerusalem, "Ein Beispiel von Assoziation durch unbewusste Mittelglieder" (1892).

[57] Wundt, "Sind die Mittelglieder einer mittelbaren Assoziation bewusst oder unbewusst?" (1892).

[58] Scripture, "Über den assoziation Verlauf der Vorstellungen" (1889).

[59] William Smith, *Zur Frage der mittelbaren Assoziation* (1894).

[60] Münsterberg, *Beitràge zur experimentellen Psychologie*, IV (1892), p. 9. Münsterberg states emphatically: "Indirect associations through unconscious intermediate links do not exist." All that can be said is that there were none in his experiments.

[61] There are several good examples of indirect associations in Cordes, "Experimentelle Untersuchungen über Assoziationen" (1899), pp. 70, 71, 75. The supposition that the intermediate links of indirect associations are unconscious is for Cordes "a theoretical construction which it will never be possible to prove empirically, for unconscious psychic phenomena cannot be experienced." The author would in any case modify this apodictic statement if he were at all acquainted with the results of hypnotism.

[62] See Jung, "On Simulated Insanity."

[63] In women by no means all egocentric references emerge freely, for the simple reason that the experimenters are men.

[64] Difference between the figure for identical grammatical form under normal conditions and the average number of distraction experiments.

[65] From the predicate-type class, containing three sub-groups, only one subject was used for calculation.

[66] These plastic images correspond roughly to Ziehen's individual images. We purposely did not ask about them during the experiment, to avoid directing attention to them by this suggestion. In many individuals only a slight effort of attention is needed to produce plastic images immediately. In this case only the vague and general verbal images are suppressed, which can happen half unconsciously with appropriate suggestion, particularly with unpractised subjects.

[67] That is, it concentrates attention upon itself.

[68] By this we mean, of course, merely our experimental conditions. Under the influence of fatigue or alcohol the predicates would probably decrease; this, however, remains to be investigated.

[69] The fact that the majority of the subjects are Swiss, and therefore working under the more difficult linguistic conditions, must be remembered here.

[70] It must be noted here that of all the eleven predicate types used in these calculations only two are uneducated and of these only one is a woman.

[71] This can be explained from the psychology of the predicate type. The subjects of this type are distinguished by their particularly vivid images. Therefore, they always see the adjective as the property of a definite object, which they then name in their reactions.

[72] We use the term “repression” in the sense of Breuer and Freud, to whose work *Studies on Hysteria* we are indebted for valuable stimulus for our work.

[1] [First published as “Analyse der Assoziationen eines Epileptikers,” *Journal für Psychologie und Neurologie*, V (1905):2, 73–90. Republished in *Diagnostische Assoziationsstudien*, Vol. I, pp. 175–92 (III. Beitrag). Translated by M. D. Eder in *Studies in Word-Association*, pp. 206–26. See supra, par. 1, n.1.]

[7] “The Associations of Imbeciles and Idiots” (1904).

[8] “Hebung epileptischer Amnesien durch Hypnose” (1902).

[9] “The Associations of Normal Subjects,” supra.

[10] [German *tragen* has both these meanings. All reaction-time data in this paper are in seconds.]

[11] See “The Associations of Normal Subjects,” par. 429, supra. This case concerns a love-affair that ended unhappily and, moreover, with distressing circumstances that fully explain the strong affect.

[12] Ibid., par. 432.

[13] A further reason that, in Bleuler’s view, facilitates the occurrence of sentences in mental defectives is that it is difficult for them not only to understand a word outside the context of a sentence, but even to think words outside a sentence context.

[14] See “The Associations of Normal Subjects,” par. 427.

[15] Case 13 of Wehrlin’s paper.

[16] [German *Falle*: “fall” was substituted for the correct translation, “trap,” which would not have made sense in this example.]

[17] Cf. “The Associations of Normal Subjects,” par. 408 (2).

[18] Such reactions differ distinctly from certain reactions that can occasionally be obtained from loquacious imbeciles. I quote the following as examples of this type:

Sunday	consists of a day when one does nothing, when one goes to church
mountain	a high mountain, with houses or without houses
salt	something to salt with. One salts meat
exercise-book	is made of paper. One makes a newspaper of it
ring	on the finger—jewelry—chain
attendant	someone who attends in hospitals, institutions, almshouses

piano	where music is, on the top floor where the organ is, the Misses have played it, next to it (even tells a story of an organ-player)
to swim	in the lake, in the water, in the Rhine, one needs swimming trunks
to cook	necessary for the meal, soup, flour, meat, pots and pans, casserole
star	parts of the sky, system of planets, sun, moon, and stars

In these associations the emphasis and confirmations of the epileptic are absent; they do not express the emotional moment so well. They are more enumerations, which frequently appear like flights of ideas; the train of thought progresses and does not stick anxiously to the stimulus-word.

[19] [German *Naturalie*, which is felt to be a foreign word.]

[20] Certain stimulus-words can touch off a feeling-toned complex of ideas that is very important for the individual. This results in certain disturbances of the association which we have described as “complex-characteristics,” such as: abnormally long reaction-times, repetition of the stimulus-word, abnormal wording of the critical or of the following reaction.

[21] *Intention* is in any case a very insidious word for certain people.

[22] [fR-T = reaction-time of the following association.]

[23] Cf. also Freud’s observations in *The Psychopathology of Everyday Life*.

[24] I find in normal subjects that reactions constellated by a conscious or unconscious complex often show abnormally long reaction-times; in some cases the emotional charge can even involve the following reaction, for which the reaction-time also becomes extended.

[25] See Aschaffenburg, “Experimentelle Studien über Assoziationen” (1896 ff.). (For the calculation, see my later paper on reaction-times.)

[26] This suggestion would also explain the epileptic perseveration in terms of the abnormality of the feeling-tone. It is, however, not unthinkable that the epileptic idea is abnormal in that it lasts longer than in the normal subject, and therefore produces a number of associations that still belong to the initial idea. Under these circumstances one could certainly expect relatively numerous perseverations of the contents. There is, however, none present in this case.

[27] Rr = repetition of the stimulus-word in the following reaction.

[1] [Originally published as “Über das Verhalten der Reaktionszeit beim Assoziationsexperimente,” *Journal für Psychologie und Neurologie*, VI (1905): 1/2, 1–36; republished separately the same year as Jung’s *Habilitationsschrift*, i.e., treatise submitted for recognition as lecturer in psychiatry at the University of Zurich. Republished in *Diagnostische Assoziationsstudien*, Vol. I, pp. 193–228 (IV. Beitrag). Translated by M. D. Eder as “Reaction-time in Association Experiments,” *Studies in Word-Association*, pp. 227–65. See supra, par. 1, n.1.]

[In this study, the symbol σ = a millisecond, or 1/1000th of a second.]

[16] “Experimentelle Studien über Assoziationen.”

[17] Among the uneducated male subjects there is a young man of a slightly hysterical disposition, whose mental soundness we may have overestimated. His probable mean is no less than 3.4 seconds (an abnormally high value!). If this doubtful subject is left out, then the mean for men is only 1.6 seconds.

[18] “Eine experimentelle Studie über die Assoziation in einem Falle von Idiotie” (1900).

[19] “The Associations of Imbeciles and Idiots” (orig. 1904).

[20] Münsterberg, Kraepelin, and Aschaffenburg have all dealt with this question. Kraepelin found that, in about 90% of cases, where the stimulus-word was given in the form of a noun, the reaction was also given as a noun; Aschaffenburg, testing 16 subjects, found the same result in 81%. It may be

remarked that he used only nouns as stimulus-words, on principle. This fact induces the subjects to indulge in perseverating with the same reaction-form; that is why these figures have only limited value. By “grammatical form” I understand merely noun, adjective, or verb.

[21] I have counted them in newspapers and in interview articles and have found approximately the same proportion.

[22] “The Associations of Normal Subjects,” supra, pars. 475ff.

[23] The individual values on which this table is based vary between 1.0 and 4.4 seconds.

[24] One could easily pose a whole series of questions on this theme; for instance, what is the reaction-time when verb is followed by verb and noun by noun? how does this vary between different subjects? and so on. This, however, would lead us too far afield.

[25] “The Associations of Normal Subjects,” supra, par. 445.

[26] The individual mean-values on which this table is based vary between 1.0 and 4.0 seconds.

[27] “Die Ideenassoziation des Kindes.”

[28] “Zur qualitativen Untersuchung der Assoziationen.”

[29] Ziehen first drew our attention to the fact that in cases of prolonged reaction-time a “relatively strong emotional charge” often occurred. Op. cit., 2nd contrib., p. 36.

[30] “The Associations of Normal Subjects,” supra.

[31] Ibid., par. 449.

[32] On perseveration, cf. Müller and Pilzecker, “Experimentelle Beiträge zur Lehre von Gedächtnis” (1900).

[33] Cf. R.143, *blood*, infra.

[34] Cf. Müller and Pilzecker, op. cit.

[35] “The Associations of Normal Subjects,” supra, pars. 350ff.

[36] [This association derives from the German phrase “der Zahn der Zeit” = “the tooth (i.e., ravages) of time.”]

[36a] [Cf. “The Psychology of Dementia Praecox,” par. 110, where the same association is rendered in translation as *mild / bed; child / bed.*]

[37] In a case of this kind, more exact timing would be desirable.

[38] “The Association of Normal Subjects,” supra, pars. 211f.

[39] From this we can also gather that those who equate psyche with consciousness actually take *partem pro toto*.

[40] Cf. Freud, *The Psychopathology of Everyday Life* (orig. 1904).

[41] Only 4% of the associations can safely be related to other complexes.

[42] [*Tötig*, not actually a word, suggests *töten*, ‘to kill.’]

[43] [*Dreck*, which also means excrement.]

[44] Cf. *The Interpretation of Dreams* (orig. 1900).

[45] Riklin, “Zur Psychologie hysterischer Dämmerzustände und des Ganser’schen Symptoms” (1904).

[46] A similar word-automatism (Bunau-Varilla) is reported in “The Associations of Normal Subjects,” supra, par. 451.

[47] [*Wortschaft*, not an actual word; perhaps a mistake for *Wortschatz*, ‘vocabulary’; but cf. above, p. 243, no. 191, *Wirtschaft*.]

[48] Cf. also the “complex-characteristics” in our earlier investigation: “The Associations of Normal Subjects,” supra, par. 417.

[49] [This case is also discussed in “The Psychological Diagnosis of Evidence,” infra.]

[50] [Famous Viennese dermatologist (1837–1902).]

[51] The concept of *repression*, which I use on many occasions in my analyses, requires a brief explanation. In Freud’s works this concept (which in any case the meaning of the word itself indicates) has the character of an active function, frequently a function of consciousness. In hysteria one may, however, get the impression that *repression* equals deliberate forgetting. With normal subjects it might, however, be a more passive “sliding into the background”; at least here repression seems to be something unconscious, to which we can only indirectly attribute the character of something willed or something *wished*. If, nevertheless, I speak of repressing or, better, concealing, this can be taken as a metaphor from the psychology of the conscious. Essentially it comes to the same thing because objectively it does not matter one way or the other whether a psychic process is conscious or unconscious. (Cf. Bleuler, “Versuch einer naturwissenschaftlichen Betrachtung der psychologischen Grundbegriffe” (1894).)

[52] I must observe that the analysis of the associations of an uneducated subject would take a very different and more complicated form. As explained by Riklin and myself, the uneducated subject is inclined to concentrate on the meaning of the stimulus-word; for this reason his reaction-times are longer and it would be difficult to decide to what extent feelings or attitudes account for these.

[53] The stimulus-words bracketed together followed immediately on each other in the test series.

[54] The stimulus-word in square brackets is given because it seems more likely to arouse a complex than *window* or *inn*.

[1] [First published as “Experimentelle Beobachtungen über das Erinnerungsvermögen,” *Zentralblatt für Nervenheilkunde und Psychiatrie* (Leipzig), XXVIII (1905; n.s. XVI): 196 (Sept.), 653–66. It was not included in the first volume of *Diagnostische Assoziationsstudien*, whose contents Jung referred to in the opening sentence, and it is here first republished.]

[2] Freud, “The Neuro-Psychoses of Defence” (orig. 1894), “The Psychical Mechanism of Forgetfulness” (1898), “Screen Memories” (1899), *The Psychopathology of Everyday Life* (orig. 1904).

[3] Freud, *The Interpretation of Dreams* (1900).

[4] See my “The Reaction-time Ratio in the Association Experiment,” supra.

[5] Hans Gross, “Zur psychologischen Tatbestandsdiagnostik” (1905); Wertheimer and Klein, “Psychologische Tatbestandsdiagnostik” (1904); Alfred Gross, “Zur psychologischen Tatbestandsdiagnostik als kriminalistisches Hilfsmittel” (1905); Stern, “Psychologische Tatbestandsdiagnostik” (1905); Hans Gross, “Zur Frage des Wahrnemungsproblems” (1905).

[6] [In the German version, the items of this list were not numbered. They have now been numbered to facilitate comparison with the list for Case No. II. The list for Case No. I omits, perhaps inadvertently, 51, *frog.*]

[7] The complex phenomena are comprehensively presented in my “The Reaction-time Ratio in the Association Experiment”; see supra.

[7a] [Jung is apparently referring to the first column of reproductions, in which there are actually 12, not 13, incorrect reproductions. There are 14 in the second column.]

[8] “The Reaction-time Ratio in the Association Experiment.”

[9] [German *Engel/-hof;* in Switzerland, a name sometimes given to a farm or house.]

[13] Cf. Riklin, “Analytische Untersuchungen der Symptome und Assoziationen eines Falles von Hysterie (Lina H.)” (1905).

[1] [First published in "Psychoanalyse und Assoziationsexperiment," *Journal für Psychologie und Neurologie*, VII (1906): 1–2, 1–24. Republished in *Diagnostische Assoziationsstudien*, Vol. I, pp. 258–81 (VI. Beitrag). Translated by M. D. Eder in *Studies in Word-Association*, pp. 297–321. See supra, par. 1, n. 1.]

[2] "Fragment of an Analysis of a Case of Hysteria" (orig. 1905).

[3] [Paul Julius Möbius (1853–1907), German neurologist who influenced Freud.]

[4] [For Jung's reviews of books by Leopold Lowenfeld and Willy Hellpach, see Vol. 18, *Miscellany.*]

[5] See supra, pars. 602 ff.

[6] Wertheimer, "Experimentelle Untersuchungen zur Tatbestandsdiagnostik" (1905). Wertheimer and Klein, "Psychologische Tatbestandsdiagnostik" (1904).

[7] "Zur psychologischen Tatbestandsdiagnostik" (1905).

[8] "Die Assoziationsmethode in Strafprozess" (1906). Grabowsky, "Psychologische Tatbestandsdiagnostik" (1905).

[9] Bleuler, "Versuch einer naturwissenschaftlichen Betrachtung der psychologischen Grundbegriffe" (1894) and "Consciousness and Association" (orig. 1905).

[10] Jung, "Experimental Observations on the Faculty of Memory," supra.

[11] The incorrectly reproduced associations are in italics. + = correct reproduction. r. = here the patient repeated the stimulus-word quickly in the reaction. One frequently meets this phenomenon in and after complex-reactions.

[12] Cf. Jung, "The Reaction-Time Ratio in the Association Experiment," etc.

[13] I cannot deal here with the justification of these inferences. See ibid.

[14] — = not reproduced.

[15] [The association in German seems to have been suggested by *Bergwerk, 'mine.'*]

[16] In order to set the complex-disturbances in relief, I am adding all the perseveration phenomena and also the gradually decreasing times of the subsequent reactions.

[17] [See supra, n. 15.]

[18] The reproaches are originally restricted to the sexual complex but, according to our experience, are soon applied to a wider field.

[19] Cf. the reference to this maid in the first session.

[20] Cf. Jung, "On the Psychology and Pathology of So called Occult Phenomena" (1902).

[21] [German *fremd/Heimweh;* "fremd" is an adjective the literal translation of which ('strange') would be misleading. The noun had therefore to be used, although not strictly apposite.]

[22] With this one can also compare the fact that many sexually perverted persons (fetishists) have acquired their abnormality through an incidental sexual event (see Krafft-Ebing, *Psychopathia Sexualis*).

[1] [First published as “Die psychologische Diagnose des Tatbestandes,” *Schweizerische Zeitschrift für Strafrecht* (Bern), XVIII (1905), 369–408, and again in *Juristische-psychiatrische Grenzfragen* (Halle), IV (1906): 2, 3–47; republished as a pamphlet the same year under the same auspices, and again in 1941 by Rascher, Zurich and Leipzig.

[For a preliminary report of the case described in Part II (pars. 770ff.) see “On the Psychological Diagnosis of Facts,” *Psychiatric Studies*, Vol. 1 of the *Collected Works*. Jung wrote that report on the actual evening of the day during which he had conducted the test herein described more fully.

[While *Tatbestand* means ‘facts,’ as translated in the title of the preliminary report, it may mean ‘evidence’ in a forensic context. Cf. Freud’s “Tatbestandsdiagnostik und Psychoanalyse,” translated in the Standard Edn., IX, as “Psychoanalysis and the Establishment of the Facts in Legal Proceedings” (main title) and as “Psycho-analysis and Legal Evidence” (page headings).]

[2] [I.e., the series *Beiträge zur Psychologie der Aussage*, which Stern published in Leipzig].

[3] “Psychometric Experiments” (1897).

[4] Strictly speaking, these are of course not associations, only remote verbal reflections of the purely psychological process of association.

[5] “Experimentelle Untersuchungen über die Assoziationen der Vorstellungen” (1883).

[21] “Zur psychologischen Tatbestandsdiagnostik” (1905) and “Zur Frage des Wahrnehmungsproblems” (1905).

[22] “Zur psychologischen Tatbestandsdiagnostik als kriminalistisches Hilfsmittel” (1905–6).

[23] “Die Assoziationsmethode im Strafprozess” (1906), p. 19.

[24] “Psychologische Tatbestandsdiagnostik” (1905–6), p. 145.

[25] Breuer and Freud, *Studies on Hysteria* (orig. 1895); Freud, *The Interpretation of Dreams* (orig. 1900).

[26] “Psychologische Tatbestandsdiagnostik” (1905).

[27] Bleuler, “Upon the Significance of Association Experiments”; Jung and Riklin, “The Association of Normal Subjects,” supra; Wehrlin, “The Associations of Imbeciles and Idiots”; Jung, “An Analysis of the Associations of an Epileptic,” supra; also, Riklin, “Die diagnostische Bedeutung des Assoziationsversuches bei Hysterischen” (1904) and “Analytische Untersuchungen der Symptome und Assoziationen eines Falles von Hysterie” (1905).

[28] Alfred Gross replied in detail to Kraus’s deliberations in “Zur psychologischen Tatbestandsdiagnostik” (1905).

[29] See n. 25, supra.

[30] “Zur psychologischen Tatbestandsdiagnostik” (1905).

[31] For a preliminary report of the case, see “On the Psychological Diagnosis of Facts,” *Coll. Works*, Vol. 1.

[32] The delinquent comes from a religious family.

[33] [German *klagen* has both meanings.]

[34] [German *arm* or *Arm* has both meanings.]

[35] *False* means that he has stolen from his benefactor.

[36] So many months in jail.

[37] The method of the “probable mean” (Kraepelin) consists in putting the numbers into a sequence according to their magnitude and then simply taking the middle number. As to the advantages of this method, cf. Jung, “The Reaction-time Ratio in the Association Experiment,” supra.

[38] The intentionally inserted stimulus-words relating to the complex are italicized in each case.

[39] The words indicating the complex are also italicized. [In this case, the reaction was stammered: German *frei-freigebig*, ‘free-freely giving.’]

[40] [Orig. *Mechanismus*, not a German word.]

[41] Cf. “The Reaction-time Ratio in the Association Experiment.”

[42] The minus sign indicates that the reaction could not be remembered.

[42a] [German: *aufpassen/verfehlen* … *st-verstecken*, with *stehlen* conjectured.]

[43] Unfortunately the reaction-time could not be assessed here because of a breakdown of the stop-watch.

[44] [German *Kommode*, and the original reaction *bequem* has the same meaning, “comfortable,’ as *kommode.*]

[45] See Wehrlin, “The Associations of Imbeciles and Idiots.”

[46] In this respect there are characteristic differences between words, e.g., the probable mean for concrete nouns is 1.67 secs., for general concepts 1.95 secs., adjectives 1.70 secs., verbs 1.90 secs. See “The Reaction-time Ratio in the Association Experiment.”

[47] The reasons are given in detail in “The Reaction-time Ratio in the Association Experiment.”

[48] We have here, however, to consider that the reduction of the Informed to the level of the Culprit is not a quite unobjectionable procedure, because the times can only be extended upwards and not downwards. Finally, it is also characteristic that the innocent can act quickly, that is, without hesitation.

[49] [The last sentence was omitted in the 1906 version.]

[1] [Originally published as “Assoziation, Traum und hysterisches Symptom,” *Journal fur Psychologie und Neurologie*, VIII (1906):1–2,25–60. Republished in *Diagnostische Assoziationsstudien*, Vol. II (1909), 31–66 (VIII. Beitrag). Translated by M. D. Eder as “Association, Dream, and Hysterical Symptoms,” *Studies in Word-Association*, pp. 354–95. See supra, par. 1, n. 1.]

[2] Jung, “Psychoanalysis and Association Experiments,” supra; Riklin, “Cases Illustrating the Phenomena of Association in Hysteria” (1906).

[3] [See Meige and Feindel, *Tics and Their Treatment* (orig. 1902).]

[3a] [See supra, par. 655, n. 9.]

[4] Cf. “The Associations of Normal Subjects,” supra, pars. 20ff.

[5] Ibid., Table F.

[6] A similar case of diversion phenomenon is reported supra, pars. 170ff., where, however, quite a recent affect formed the cause of the interference.

[7] This is not actually the case, however, because already in Test I the patient showed the beginnings of a less superficial association type.

[8] Thus the patient now shows a reaction-type that we not infrequently see in uneducated people: a great many internal associations, few external ones, and very few sound reactions.

[9] The failures were calculated at 20 secs. each.

[10] Failure or incorrectness of reproduction is indicated in square brackets.

[11] Cf. “Experimental Observations on the Faculty of Memory,” supra.

[12] Transference [*Transposition*] to the doctor; see Freud, “Fragment of an Analysis of a Case of Hysteria” (orig. 1905).

[13] *Jokes and Their Relation to the Unconscious* (orig. 1905), p. 170.

[14] [German *Tanzboden*, lit. ‘dance-floor,’ has the sense of a low-class dance-hall.]

[14a] [This apparently refers to a performance or calculation test, devised by Kraepelin, and still in use at the Burghölzli. The patient has to add pairs of digits and write the sum down in an exercise-book, in which the experimenter enters a mark at each minute in order to indicate the patient’s rate of performance. Dr. C. A. Meier has kindly supplied this information.]

[15] See Bleuler’s theoretical discussions in “Consciousness and Association” (orig. 1905).

[16] We have shown that in a state of diversion of attention the indirect associations increase in such a way that a very frequent association replaces either the stimulus-word or the reaction, so that it appears as if the stimulus-word must have been misheard or that the patient reacted by a slip of the tongue. “The Associations of Normal Subjects.”

[17] [A medieval tribunal that sat in secret.]

[18] [In German, *dürren Landjäger.*]

[19] [The word used, *Sudfruchtengeschäft*, means a shop specializing in fruit from the South.]

[20] Here it should also be remembered that in the dream of the occupied room there was the call: “Stop, this is forbidden!” Perhaps my phrase made such an impression, because it was complex-

stimulating and expressed something that was of great importance for the patient (if we assume that the complex here touched actually exists!).

[21] Cf., e.g., the sleep-walking fantasies of the case that I published in my study “On the Psychology and Pathology of So-called Occult Phenomena.”

[1] [First published as “Die psychopathologische Bedeutung des Assoziationsexperimentes,” *Archiv für Kriminalanthropologie und Kriminalistik* (Leipzig). XXII (1906): 2–3 (Feb. 15), 145–62. It was Jung’s inaugural lecture, 21 October 1905, upon his appointment as lecturer in psychiatry at the University of Zurich.]

[14] “Die Ideenassoziation des Kindes” (1898–1900).

[15] “Zur qualitativen Untersuchung der Assoziationen” (1901).

[16] Of course, we sometimes find long reaction-times that are due to other causes.

[17] Cf. Jung, “The Reaction-time Ratio in the Association Experiment,” supra.

[18] Jung, “Experimental Observations on the Faculty of Memory,” supra.

[19] On hysterical associations, cf. Riklin, “Analytische Untersuchungen der Symptome und Assoziationen eines Falles von Hysterie” (1905).

[20] Jung, “The Psychological Diagnosis of Evidence,” supra.

[21] On this question, see especially the works of Sigmund Freud, to whose far-seeing psychological understanding modern psychiatry will be *very much* indebted.

[22] In order to avoid long-winded explanations in a lecture, I have expressed myself somewhat dogmatically. Dementia praecox unfortunately denotes a group of illnesses which have not yet been clearly defined clinically, and individual forms and descriptions can appear quite distinct from one another. Our experiments (whose results have not yet been published) show that the symptoms of this disease can be explained in a large number of cases as complex-phenomena. [See “The Psychology of Dementia Praecox” and other works in vol. 3, *Coll. Works.*]

[1] [First published as “Über die Reproduktionsstörungen beim Assoziationsexperiment,” *Journal für Psychologie und Neurologie*, IX (1907): 4, 188–97. Republished in *Diagnostische Assoziationsstudien*, Vol. II (1909), pp. 67–76 (IX. Beitrag). Translated by M. D. Eder in *Studies in Word-Association*, pp. 396–406. See supra, par. 1, n. 1.]

[2] [“Experimental Observations on the Faculty of Memory,” supra.]

[3] Alfred Gross, “Kriminalpsychologische Tatbestandsforschung” (1907); Heilbronner, “Die Grundlagen der psychologischen Tatbestandsdiagnostik” (1907); Isserlin, “Über Jungs ‘Psychologie der Dementia praecox,’ etc.” (1907).

[4] “The Reaction-time Ratio in the Association Experiment,” supra.

[5] The figures in these two columns give the arithmetical mean (A.M.) of the reaction-times of the associations immediately preceding the incorrectly reproduced ones: column I for the incorrectly reproduced associations with the probable mean (P.M.), column II for those below the probable mean.

[6] I.R. = incorrectly reproduced.

[7] The fourth and subsequent disturbances are not given because they are based on too small a series of numbers (less than 20). But they all considerably exceed the general arithmetical mean, if only for the reason that the number and the series of disturbed reproductions tend to increase with the length of the reaction-time.

[1] [The first of a series of lectures under the general title “The Association Method,” delivered before the Department of Psychology in celebration of the twentieth anniversary of the opening of Clark University, Worcester, Massachusetts, September, 1909. The three lectures were translated by A. A. Brill and published in the *American Journal of Psychology*, XXI (1910), in a Clark University anniversary volume (1910; the same setting of type), and in *Collected Papers on Analytical Psychology* (London and New York, 1916; 2nd edn., 1917). For the second lecture, see “The Family Constellation,” infra. The third lecture was the only one published in its original German version: see “Psychic Conflicts in a Child,” *Coll. Works*, vol. 17, prefatory note.

[The original German version of the first two lectures was thought to have been lost, but recently Jung’s holograph was found among his papers. While it has the appearance of a draft, it corresponds closely with the Brill translation. Both Freud and Jung lectured at Clark University in German; see Freud’s “On the History of the Psycho-Analytic Movement,” p. 31, and his “Five Lectures on Psycho-Analysis” (the Clark lectures), editor’s note, p. 4. Both men received honorary doctorates of law at the Clark celebration, Freud’s being in psychology and Jung’s in “education and social hygiene.”

[The present translation has been made from the holograph, in consultation with the Brill translation.]

[2] [The holograph contains merely the direction “insert,” and the list that follows here is from Brill, modified to conform to the present translation. It corresponds closely to a list that Jung customarily used in German, viz.:

1. Kopf
2. grün
3. Wasser
4. singen
5. Tod
6. lang
7. Schiff
8. zahlen
9. Fenster
10. freundlich
11. Tisch
12. fragen
13. Dorf
14. kalt
15. Stengel
16. tanzen
17. See
18. krank
19. Stolz
20. kochen
21. Tinte
22. bös

23. Nadel
24. schwimmen
25. Reise
26. blau
27. Lampe
28. sündigen
29. Brot
30. reich
31. Baum
32. stechen
33. Mitleid
34. gelb
35. Berg
36. sterben
37. Salz
38. neu
39. Sitte
40. beten
41. Geld
42. dumm
43. Heft
44. verachten
45. Finger
46. teuer
47. Vogel
48. fallen
49. Buch
50. ungerecht
51. Frosch
52. scheiden
53. Hunger
54. weiss
55. Kind
56. aufpassen
57. Bleistift
58. traurig
59. Pflaume
60. heiraten
61. Haus
62. lieb
63. Glas

64. streiten
65. Pelz
66. gross
67. Rübe
68. malen
69. Teil
70. alt
71. Blume
72. schlagen
73. Kasten
74. wild
75. Familie
76. waschen
77. Kuh
78. fremd
79. Glück
80. lügen
81. Anstand
82. eng
83. Bruder
84. fürchten
85. Storch
86. falsch
87. Angst
88. küssen
89. Braut
90. rein
91. Türe
92. wählen
93. Heu
94. zufrieden
95. Spott
96. schlafen
97. Monat
98. hübsch
99. Frau
100. schimpfen

The lists on the following pages appeared in the holograph. The graphs did not appear, though referred to.]

[3] [The holograph here contains a direction to insert the experiment from the *Rivista di psicologia applicata*, i.e., “New Aspects of Criminal Psychology” (see infra. Appendix 2). Accordingly, pars.

957–983 here are translated from the Italian of that work, where the passage is omitted to avoid repetition.]

[4] [The reaction-times are always given in fifths of a second.]

[5] [See the appendix, infra, pars. 1331ff., where the discussion of this case continues.]

[*] [In the original editions, this graph was reproduced using three colours in addition to black: blue, green, and yellow with striped effects when two or three factors applied. As a coloured graph is mentioned in the holograph, it may have been shown as a slide or chart during the lecture. The graph has been simplified and corrected in detail for this presentation.]

[1] [For bibliographical history, see n. 1 to the preceding lecture, “The Association Method.” This lecture has also been translated from the German holograph, in consultation with the Brill version. In the holograph, Jung’s title was “Die familiäre Constellation,” which Brill rendered as “The Familiar Constellations” in the 1909, 1910, and 1916 publications.

[Jung had previously published “Associations d’idées familiales,” *Archives de psychologie* (Geneva), VII: 26 (Oct., 1907), 160–68, the content of which is similar to that of the present paper; it is omitted from the *Coll. Works*. He again presented four of the graphs, and commented on the cases, in 1935 in “The Tavistock Lectures,” Lecture III (1968 edn., pp. 83ff.).]

[2] [Emma Fürst, M.D., a member of the staff of the Psychiatric Clinic of the University of Zurich. Cf. her “Statistical Investigations on Word-Associations and on Familial Agreement in Reaction Type among Uneducated Persons” (orig. 1907).]

[3] [The holograph here contains a direction to insert all of sec. 2 at p. 165 in the *Archives*, i.e., “Associations d’idées familiales” (supra, n. 1). Pars. 1000–1003 are here reproduced from the Brill translation, modified to conform with the present translation.]

[4] “Analysis of a Phobia in a Five-Year-Old Boy” (orig. 1909).

[5] [Ibid.]

[1] [Apparently written in English; published in *The Journal of Abnormal Psychology* (Boston), I (1907), 247–55. It was Jung's first publication in English and has never been republished. The present text contains slight stylistic revisions.]

[2] Cf. the report of Adolf Meyer, *Psychological Bulletin*, II (1905), 242–50; also August Hoch, in *Journal of Abnormal Psychology*, I:2 (1906).

[3] [In the 1907 publication, the reaction-time column is headed "min./sec."; but, inasmuch as in the next par. Jung states that the reaction-times are relatively short, the column heading has been corrected. But cf. above, pars. 743ff.]

[4] See bibliography at end of this article.

[5] ["On the Psychogalvanic Phenomenon in Association Experiments" (orig. 1907/8).]

[6] [Jung published the bibliography with more or less full references, which will be found in the entries in the volume bibliography.]

[1] [Originally published, in English, in *Brain: A Journal of Neurology* (London), XXX (1907): 118 (July),153–218; reprinted the same year as a small book. Frederick W. Peterson (1859–1938), M.D., was then Clinical Professor of Psychiatry, Columbia University, New York. He collaborated with A. A. Brill in the translation of Jung's *The Psychology of Dementia Praecox* (1909).

[In the present version, stylistic and terminological revisions have been made. A list of references originally at the end of the paper has been converted into footnotes.]

[2] "Über Versuche einer objektiven Darstellung von Sensibilitätsstörungen" (1897).

[3] "Zur Messung der motorischen Begleiterscheinungen psychischer Zustände" (1902).

[4] Veraguth presented his entire results to date for discussion at the second German Congress for Experimental Psychology, Würzburg, 1906, the transactions of which will be published early this year (1907). [See Veraguth, "Le Réflexe psychogalvanique" (1906 and 1907).]

[The following was inserted as a corrigendum slip in the *Brain* publication: "Dr. Jung wishes us to state that Dr. O. Veraguth, of Zurich, first made known to him the value of the galvanometer as a measure of psychical stimuli. It was after this demonstration by Dr. Veraguth that Dr. Jung began to experiment on his own account."]

[9] [Jung published this bibliography with more or less full references, which will be found in the entries in the volume bibliography.]

[1] [Translated from “Statistisches von der Rekrutenaushebung,” *Correspondenz-Blatt für Schweizer Aerzte* (Basel), XXXVI:4 (Feb. 15, 1906), 129–30. Jung served as an officer in the Swiss Army medical corps from 1901 to 1930.]

[2] One must take into consideration that the formalities of enlistment create for many people an unusual situation, owing to which they get into a state of persistent stupefaction (so-called emotional stupidity), which makes them appear more stupid than they really are.

[3] The rest came from the semi-urban population of Kriens; they were therefore omitted.

[1] [Translated from “Le nuove vedute della psicologia criminale; Contributo al metodo della ‘Diagnosi della conoscenza del fatto (Tatbestandsdiagnose),” *Rivista di psicologia applicata* (Bologna), IV:4 (July–August, 1908), 285–304. The article in Italian was translated by L. Baroncini from a German manuscript that has not been discovered. Part of the article was incorporated in Jung’s lecture “The Association Method” at Clark University, 1909; see supra, par. 929, n. 1, and infra, n. 10.]

[2] [Editorial note in the Italian, apparently by the editor of the *Rivista*, G. Cesare Ferrari, director of the provincial mental hospital at Imola:

“*Tatbestandsdiagnose* is one of those words without meaning, at least for us, that only the Germans can coin. The subject to which this inappropriate word refers is, however, so important that we must try to find a significant term.

“It is not the first time that this difficulty has arisen; terms such as ‘associations with a diagnostic purpose,’ ‘involuntary self-accusation by means of associations,’ ‘diagnosis of complexes of ideas,’ and others have been proposed. Each of these is, however, open to criticism.

“Baroncini, who has translated Jung’s original work into Italian, tries to be faithful to the German phraseology of the text. He proposes, however, to correct the term to ‘psychological diagnosis of evidence’ (*diagnosi della conoscenza del fatto*), a logical substitution that has the disadvantage of needing two pages of interpretation. For lack of a better term, we accept this phrase and we suggest that the organizers of the Congress for Psychology in Geneva may improve on it.”]

[3] For the history, literature, and technique of the experiments, see my “The Psychological Diagnosis of Evidence,” supra.

A good illustration of the laboratory experiments and of many questions about the method can be found in Alfred Gross, “Kriminalpsychologische Tatbestandsforschung” (1907).

The use of the association experiments for criminological purposes was first suggested by Wertheimer and Klein [1904].

For the general importance of the association experiments, see the Diagnostic Association Studies edited by me (1906).

[4] J. G. Schnitzler, medical dissertation, Utrecht, 1907 [= “Experimentelle Beiträge zur Tatbestandsdiagnostik” (1909)].

[5] In the reproduction method, one first collects a large number of associations, then one requests the subject to say again the words with which he had reacted to the various stimulus-words. One then finds that it is mainly such associations as indicate complexes that are easily forgotten. Cf. my “Disturbances of Reproduction in the Association Experiment,” supra.

[6] A classification of the complex-characteristics can be found in par. 935, supra.

[7] See my “The Reaction-time Ratio in the Association Experiment,” supra. I call “prolonged” those reaction-times that exceed the probable mean of all the reaction-times observed during the investigations.

[8] Cf. especially the investigations of Binswanger, “On the Psychogalvanic Phenomenon in Association Experiments.”

ISBN 0-691-01859-6 (pbk.)
MANUFACTURED IN THE UNITED STATES OF AMERICA

EDITORIAL NOTE

The importance of this volume of scientific papers for understanding Jung's researches as a whole can scarcely be overrated, even though most of them are now mainly of historical interest or represent the reflections of his later years on a subject that never ceased to engage his active psychotherapeutic endeavours.

"The Psychology of Dementia Praecox" was the culmination of Jung's early researches at the Burghölzli Hospital into the nature of the psychoses. It was the publication which established him once and for all as a psychiatric investigator of the first rank. It was the volume which engaged Freud's interest and led to their meeting. It was the research which contained the seeds of his theoretical divergence from psychoanalysis.

Jung's work on the manifestations of schizophrenia was a potent factor in the development of his theory of psychic energy and of the archetypes. He believed that, in order to account for the imagery, splitting processes, and defect in the sense of reality observable in this disease, neither the sexual theory of libido, which leads to the concept of narcissism, nor personal and genetic study is adequate. In short, the theory of archetypes becomes indispensable.

Jung was indeed one of the first to employ individual psychotherapy with schizophrenic patients. Not only this: there are clear indications in this volume of how early in this century he investigated the relationship between mental hospital administration and the course of the supposed disease-process. His Swiss forerunners, Forel and Bleuler, both men with intense psychological interests, also realized this, and the Burghölzli team did much pioneering work in changing the hospital atmosphere. Today this understanding is being gradually applied with the good results that Jung anticipated.

It may be regretted that there is no more in this volume about the psychotherapy of schizophrenia. Why is it that Jung did not write more on this subject? The answer is given in one of his later essays, "Recent Thoughts on Schizophrenia," where he states that in spite of all the developments over the years, knowledge of this disorder is still so fragmentary that he could organize his findings only in outline and in relation to individual case-studies.

The volume is divided into four parts based on their chronological sequence, except that “On Psychological Understanding” has been placed after “The Content of the Psychoses.” Though written as separate essays the two were later combined in this way by the author in both Swiss and English publications of these works.

EDITORIAL NOTE TO THE SECOND PRINTING

Because of the availability of *Experimental Researches*, Volume 2 in the *Collected Works*, the copious references herein to Jung’s papers on the word-association tests have been revised in terms of that volume. Changes of terminology and other minor revisions of text, bibliography, and index have been made.

VOLUME 3
PSYCHOGENESIS OF MENTAL DISEASE

TABLE OF CONTENTS

I

The Psychology of Dementia Praecox

Translated from *Über die Psychologie der Dementia praecox: Ein Versuch* (Halle a. S., 1907).

B. The Complex of Being Wronged
C. The Sexual Complex
D. Summary
E. Supplement
Epilogue

II

The Content of the Psychoses

Translated from *Der Inhalt der Psychose* (2nd edn., Leipzig and Vienna, 1914).

On Psychological Understanding

Translated from the Supplement to the foregoing.

III

A Criticism of Bleuler’s Theory of Schizophrenic Negativism

Translated from a critique in the *Jahrbuch für psychoanalytische und psychopathologische Forschungen* (Vienna and Leipzig), III (1911).

On the Importance of the Unconscious in Psychopathology

Written in English and published in the *British Medical Journal* (London), II (1914).

On the Problem of Psychogenesis in Mental Disease

Written in English and published in the *Proceedings of the Royal Society of Medicine* (London), XII (1919).

Mental Disease and the Psyche

Translated from “Heilbare Geisteskranke?”, *Berliner Tageblatt*, 1928.

IV

On the Psychogenesis of Schizophrenia

Written in English and published in the *Journal of Mental Science* (London), LXXXV (1939).

Recent Thoughts on Schizophrenia

Written in English and broadcast by the “Voice of America,” December 1956.

THE PSYCHOLOGY OF DEMENTIA PRAECOX

[First published as *Über die Psychologie der Dementia praecox: Ein Versuch* (Halle a. S., 1907). Translated, and with an introduction, by Frederick W. Peterson and A. A. Brill, under the present title, in the Nervous and Mental Disease Monograph Series (no. 3; New York, 1909). Retranslated in the same series by A. A. Brill alone, with a new introduction (New York and Washington, 1936). Now newly translated from the original. The 1936 Brill translation has been consulted.—EDITORS.]

FOREWORD

This work is the fruit of three years' experimental researches and clinical observations. In view of the complexity and magnitude of the material, my work cannot and does not lay claim either to finality of treatment or to absolute certainty of the statements and conclusions. On the contrary, it combines all the disadvantages of eclecticism, which to many a reader may seem so striking that he will call my work a confession of faith rather than a scientific treatise. *Peu importe!* The important thing is that I should be able to show the reader how, through psychological investigation, I have been led to certain views which I think will provoke new and fruitful questions concerning the individual psychological basis of dementia praecox.

My views are not contrivances of a roving fancy, but thoughts which matured in almost daily conversation with my respected chief, Professor Bleuler. I owe special thanks to my friend Dr. Riklin, of Rheinau, for adding considerably to the empirical material. Even a superficial glance at my work will show how much I am indebted to the brilliant discoveries of Freud. As Freud has not yet received the recognition and appreciation he deserves, but is still opposed even in the most authoritative circles, I hope I may be allowed to define my position towards him. My attention was drawn to Freud by the first book of his I happened to read, *The Interpretation of Dreams*, after which I also studied his other writings. I can assure you that in the beginning I naturally entertained all the objections that are customarily made against Freud in the literature. But, I told myself, Freud could be refuted only by one who has made repeated use of the psychoanalytic method and who really investigates as Freud does; that is, by one who has made a long and patient study of everyday life, hysteria, and dreams from Freud's point of view. He who does not or cannot do this should not pronounce judgment on Freud, else he acts like those notorious men of science who disdained to look through Galileo's telescope. Fairness to Freud, however, does not imply, as many fear, unqualified submission to a dogma; one can very well maintain an independent judgment. If I, for instance, acknowledge the complex mechanisms of dreams and hysteria, this does not mean that I attribute to the infantile sexual trauma the exclusive importance that Freud apparently does. Still less does it mean that I place sexuality so predominantly in the foreground, or that I grant it the psychological universality which Freud, it seems, postulates in view of the admittedly enormous role which sexuality plays in the psyche. As for Freud's therapy, it is at best but one of several possible methods, and perhaps does not always offer in practice what one expects from it in theory. Nevertheless, all these things are the merest trifles compared with the psychological principles whose discovery is Freud's greatest merit; and to them the critics pay far too little attention. He who wishes to be fair to Freud should take to heart the words of Erasmus: "Unumquemque move lapidem, omnia experire, nihil intentatum relinque."*

As my work is largely based on experimental researches, I trust the reader will bear with me if he finds a great many references to the *Diagnostische Assoziationsstudien*, which appeared under my editorship.[1]

Zurich, July 1906 C. G. JUNG

1. CRITICAL SURVEY OF THEORETICAL VIEWS ON THE PSYCHOLOGY OF DEMENTIA PRAECOX

[1] The literature which treats of the psychological disturbances in dementia praecox is very fragmentary, and although parts of it are quite extensive it nowhere shows any clear co-ordination. The statements of the older authors have only a limited value, because they refer now to this, now to that form of illness, which can be classified only very indefinitely as dementia praecox. Hence one cannot attribute any general validity to them. The first and somewhat more general view concerning the nature of the psychological disturbance in catatonia, so far as I know, was that of Tschisch (1886),[1] who thought that the essential thing was an *incapacity for attention*. A similar view, somewhat differently formulated, was expressed by Freusberg,[2] who stated that the automatic actions of the catatonic are associated with a weakening of consciousness, which has lost its control over the psychic processes. The motor disturbance is only a symptomatic expression of the degree of psychic tension.

[2] For Freusberg, therefore, the motor catatonic symptoms are dependent on corresponding psychological symptoms. The "weakening of consciousness" resembles the quite modern view of Pierre Janet. That there is a disturbance of attention is also confirmed by Kraepelin,[3] Aschaffenburg,[4] Ziehen, and others. In 1894 we encounter for the first time an *experimental psychological* work on the subject of catatonia: Sommer's "On the Theory of 'Inhibition' of Mental Processes."[5] The author makes the following statements which are of general significance:

1. The process of ideation is slowed down.

2. The patient is so fascinated by pictures shown to him that he can tear himself away from them only with difficulty.

[3] The frequent *blockings* (prolongations of reaction time) are explained by Sommer as visual fixation.[6] The state of distractibility in normal persons occasionally shows similar phenomena; e.g., “amazement” and “staring into space.” With this comparison of the catatonic state to normal distractibility Sommer affirms much the same thing as Tschisch and Freusberg, namely that there is a reduction of attention. Another phenomenon closely related to visual fixation, according to Sommer, is catalepsy; he considers it “in all cases a phenomenon of entirely psychic origin.” This view of Sommer’s conflicts sharply with that of Roller, with whom Clemens Neisser is in entire agreement.

[4] Says Roller: “The ideas and sensations that reach perception in the insane person and force themselves into the field of consciousness arise from the morbid state of the subordinate centres, and when active apperception, or attention, comes into play it is fixated by these pathological perceptions.”[7]

[5] In this connection Neisser remarks: “Wherever we look in insanity we find something different, something strange; processes that cannot be explained on the analogy of normal psychic life. The logical mechanism in insanity is set in motion not by apperceptive or associative conscious activity but by pathological stimuli lying below the threshold of consciousness.”[8] Neisser thus agrees with Roller’s view, but it seems to me that this view is not quite free from objections. First, it is based on an anatomical conception of psychic processes—a conception that cannot be cautioned against too strongly. What significance “subordinate centres” have in the formation of psychic elements (ideas, sensations, etc.) we do not know at all. An explanation of this kind is merely a matter of words.

[6] Second, the Roller-Neisser view seems to presuppose that outside consciousness the psyche ceases to exist. From the psychology of the French school and from our experiences with hypnotism it is evident that this is not so.

[7] Third, if I have understood him correctly, by “pathological stimuli lying below the threshold of consciousness” Neisser must mean cell-processes in the cortex. This hypothesis goes too far. All psychic processes are correlates of cell-processes, according to both the materialistic view and that of psychophysical parallelism. So it is nothing out of the ordinary if the psychic processes in catatonia are correlates of a physical series. We know that the normal psychic

series develops under the constant influence of countless psychological constellations of which we are as a rule unconscious. Why should this fundamental psychological law suddenly cease to apply in catatonia? Is it because the ideational content of the catatonic is foreign to his consciousness? But is it not the same in our dreams? Yet no one will assert that dreams originate so to speak directly from the cells without psychological constellations. Anyone who has analysed dreams according to Freud’s method knows what an enormous influence these constellations have. The appearance of strange ideas in consciousness which have no demonstrable connection with previous conscious contents is not unheard of either in normal psychology or in hysteria. The “pathological ideas” of catatonics have plenty of analogies in normal as well as in hysterical persons. What we lack is not so much comparative factual material as the key to the psychology of catatonic automatism. For the rest, it always seems to me rather risky to assume something absolutely new and strange in science.

[8] In dementia praecox, where as a matter of fact countless normal associations still exist, we must expect that until we get to know the very delicate processes which are really specific of the disease the laws of the normal psyche will long continue to play their part. To the great detriment of psychopathology, where the only thing we are beginning to agree about is the ambiguity of our applied concepts, our knowledge of the normal psyche is unfortunately still on a very primitive level.

[9] We are indebted to Sommer[9] for further stimulating studies on the associations of catatonics. In certain cases the associations proceed in a normal way but are suddenly interrupted by an apparently quite disconnected, strangely “mannered” combination of ideas, as the following example will show:[10]

dark	green
white	brown
black	“good day, William”
red	brown

[10] These “erratic” associations were also observed by Diem,[11] who conceived of them as sudden “whims.” Sommer justly considers them an important criterion for catatonia. The “pathological inspirations” described by Breukink,[12] following Ziehen, were observed by these authors in insane patients and were found exclusively in dementia praecox, especially in its paranoid forms, where

"inspirations" of every kind play a well-known role. Bonhoeffer's "pathological ideas" probably refer to a similar phenomenon.[13] The question raised by Summer's discovery has naturally not been settled; but, until we are better informed, the phenomena observed by different authors and designated with almost the same names must for the present be grouped under one heading. Although it would seem from clinical experience that "pathological ideas" occur only in dementia praecox (we naturally discount the falsifications of memory which often appear suddenly in organic dementia and in Korsakow's syndrome), I would like to point out that in hysteria, especially in cases that never reach the clinic, "pathological ideas" play a large part. The most interesting examples are reported by Flournoy.[14] I have observed similar sudden irruptions of altered psychological activity in a very clear case of hysteria,[15] and recently I was able to confirm it again in a similar case. Finally, as I have shown,[16] the sudden disturbance of association by the irruption of apparently strange combinations of ideas occurs also in normal people. The "erratic" association or "pathological idea" may therefore be a widespread psychological phenomenon which, we may at once agree with Sommer, appears in its most glaring form in dementia praecox.

[11] Furthermore, in examining the associations of catatonics Sommer found numerous clang associations[17] and stereotypies. By "stereotypy" he meant the frequent reappearance of previous reactions. In our association experiments we called this "repetition." The reaction times showed enormous fluctuations.

[12] In 1902, Ragnar Vogt[18] again took up the problem of catatonic consciousness. He started from the Müller-Pilzecker investigations[19] by considering mainly their observations on "perseveration." According to Vogt, the persistence of psychic processes or their correlates, even after they have been superseded in consciousness by other ideas, is the normal analogy of catatonic processes of perseveration (verbigeration, catalepsy, etc.). Hence the capacity of the psychophysical functions for perseveration must be especially great in catatonia. But as, according to the Müller-Pilzecker investigations, perseveration becomes very marked only when no new content has impressed itself on consciousness,[20] Vogt assumes that perseveration is possible in catatonia only because no other conscious processes of interest to the patient are taking place. One must therefore assume a certain restriction of consciousness. This would also explain the resemblance between hypnotic and catatonic states.[21] The impulsive actions of catatonics are likewise explained by Vogt on the basis of restriction of consciousness, which prevents inhibitions from

intervening. Vogt has evidently been influenced by Pierre Janet, for whom "restriction of consciousness" and "reduction of attention" are the same as "abaissement du niveau mental."[22] So here again, though in a somewhat more modern and more generalized form, we meet the view already mentioned, that in catatonia there is a disturbance of attention, or, to express it more broadly, of the positive psychic performance.[23] Vogt's reference to the analogy with hypnotic states is interesting, but unfortunately he describes it only in outline.

[13] Similar views are expressed by Evensen.[24] He draws a skilful parallel between catatonia and distractibility, and maintains that absence of ideas in a restricted field of consciousness is the basis of catalepsy, etc.

[14] A painstaking and thorough examination of catatonic psychology is to be found in the thesis of René Masselon.[25] He maintains from the start that its chief characteristic is reduction of attention ("distraction perpétuelle"). As is to be expected from his French training in psychology, he conceives of attention in a very broad and comprehensive sense: "Perception of external objects, awareness of our own personality, judgment, the feeling of rapport, belief, certainty, all disappear when the power of attention disappears."[26]

[15] As this quotation shows, a very great deal depends on attention as Masselon conceives it. He concludes that the commonest features of the catatonic state are "apathy, aboulia, loss of intellectual activity." A brief consideration of these three abstractions will show that at bottom they are all trying to say the same thing; indeed, throughout his work, Masselon is constantly endeavouring to find the word or simile that will best express the innermost essence of his correct feeling. However, no concept need be quite so many-sided, just as there is no concept that has not had a one-sided and limited connotation forced upon it by some school or system. Masselon can best tell us what he feels about the essence of dementia praecox if we listen to the wording of some of his statements: "The habitual state is emotional apathy … these disturbances are intimately connected with disturbances of intelligence: they are of the same nature … the patients manifest no desires … all volition is destroyed … the disappearance of desire is bound up with all the other disturbances of mental activity … a veritable cramping of cerebral activity … the elements [of the mind] show a tendency to live an individual life, being no longer systematized by the inactive mind."[27]

[16] In Masselon's work we find an assortment of views which he feels all go back to one root, but he cannot find this root without obscuring his work. Yet

despite their shortcomings, Masselon's researches contain many useful observations. Thus he finds a striking resemblance to hysteria, marked self-distractibility of the patients to everything, especially to their own symptoms (Sommer's "visual fixation"), fatiguability, and a capricious memory. German critics have reproached him for this last statement, but quite unjustly when we consider that Masselon really means only the capacity for reproduction. If a patient gives a wrong answer to a direct question, it is taken by the German school as an "irrelevant answer," as negativism; in other words, as active resistance. Masselon regards it rather as an *inability to reproduce*. Looked at from the outside, it can be both; the distinction depends only on the different interpretations we choose to give of the phenomenon. Masselon speaks of a "true obscuration of the memory-image" and regards the disturbance of memory as the "disappearance from consciousness of certain memories, and the inability of the patient to find them again."[28] The contradiction between the two views can be resolved without difficulty if one considers the psychology of hysteria. If an hysterical patient says during the anamnesis, "I don't know, I have forgotten," it simply means, "I cannot or will not say it, for it is something very unpleasant."[29] Very often the "I don't know" is so clumsy that one can immediately discern the reason for not knowing. I have proved by numerous experiments that the faults (failures to react) which occur during the association test have the same psychology.[30] In practice it is often very difficult to decide whether hysterical patients really do not know or whether they simply cannot or will not answer. Anyone who is accustomed to investigating dementia praecox cases will know how much trouble he has to take to obtain the correct information. Sometimes one is certain that the patients know, sometimes there is a "blocking" that gives the impression of being involuntary, and then again there are cases where one is obliged to speak of "amnesia," just as in hysteria, where it is only a step from amnesia to not wanting to talk. Finally, the association test shows us that these phenomena are all present, in the bud, in normal people.[31]

[17] For Masselon the disturbance of memory comes from the same source as the disturbance of attention, though what this source may be is not clear. As if in contradiction to this, he finds ideas that obstinately persist. He qualifies them as follows: "Certain memories that once were more intimately connected with the affective personality of the patients tend to reproduce themselves unceasingly and to occupy consciousness continually … the memories that persist assume a stereotyped form … thought tends to coagulate (*se figer*)."[32] Without attempting to produce any further proof Masselon declares that the stereotyped

ideas (i.e., the delusions) are associations of the personality complex. It is a pity that he does not dwell longer on this point, for it would have been very interesting to know how far, for instance, a few neologisms or a "word salad" are associations of the personality complex, since these are often the only vestiges that still give us a clue to the existence of ideas. That the mental life of the dementia praecox patient "coagulates" seems to me an excellent simile for the gradual torpidity of the disease; it characterizes most pregnantly the impression that dementia praecox must have made on every attentive observer. Masselon naturally found it quite easy to derive "command automatism" (*suggestibilité)* from his premises. Concerning the origin of negativism he has only vague conjectures to offer, although the French literature on obsessional states would afford him any number of starting points for analogical explanations. Masselon also tested the associations experimentally, finding numerous repetitions of stimulus words and frequent "whims" of an apparently quite fortuitous nature. The only conclusion he came to from these experiments was that the patients were unable to pay attention. The conclusion is right enough, but Masselon spent too little time on the "whims."

[18] From the main results of Masselon's work it can be seen that this author, like his predecessors, is inclined to assume a quite central psychological disturbance,[33] a disturbance that sets in at the vital source of all the mental functions; that is, in the realm of apperception, feeling, and appetition.[34]

[19] In his clear elucidation of the psychology of feeble-mindedness in dementia praecox Weygandt, following Wundt, calls the, terminal process of the disease "apperceptive deterioration."[35] As we know, Wundt's conception of apperception is an extremely broad one; it covers not only Binet's and Masselon's conception of attention but also Janet's "fonction du réel,"[36] to which we shall return later. The broadness of Wundt's conception of apperception in the sense indicated is borne out by his own words: "That state which accompanies the clearer comprehension of a psychic content and is characterized by special feelings, we call 'attention'; the single process by which any psychic content is brought to clear comprehension, we call 'apperception.'"[37] The apparent contrast between attention and apperception can be resolved as follows: "Accordingly, attention and apperception are expressions for one and the same psychological fact. We choose the first of these expressions in order to denote the subjective side of this fact, the accompanying feelings and sensations; by the second we mean mainly the

objective consequences, the alterations in the quality of the conscious contents.”[38]

[20] In the definition of apperception as “the single process by which any psychic content is brought to clear comprehension,” much is said in a few words. According to this, apperception is volition, feeling, affectivity, suggestion, compulsion, etc., for these are all processes which “bring a psychic content to clear comprehension.” In saying this we do not wish to make any adverse criticism of Wundt’s idea of apperception, but merely to indicate its enormous scope. It includes every positive psychic function, and besides that the progressive acquisition of new associations; in other words, it embraces nothing less than all the riddles of psychic activity, both conscious and unconscious. Weygandt’s conception of apperceptive deterioration thus expresses what Masselon only dimly sensed. But it expresses the psychology of dementia praecox merely in general terms—too general for us to be able to deduce from it all the symptoms.

[21] Madeleine Pelletier, in her thesis,[39] investigates the process of ideation in manic flight of ideas and in “mental debility,” by which we are to understand clear cases of dementia praecox. The theoretical standpoint from which she considers flight of ideas agrees in essentials with that of Liepmann,[40] a knowledge of whose work I must take for granted.

[22] Pelletier compares the superficial course of association in dementia praecox to flight of ideas. Characteristic of flight of ideas is the “absence of any directing principle.” The same is true of the course of association in dementia praecox: “The directing idea is absent and the state of consciousness remains vague without any order in its elements.” “The only mode of psychic activity which in the normal state can be compared to mania is the daydream, although daydreaming is more the mode of thinking of the feeble-minded than of the manic.”[41] Pelletier is right in seeing a great resemblance between normal daydreaming and the superficial associations of manics, but that is true only when the associations are written down on paper. Clinically, however, the manic does not at all resemble a dreamer. The author evidently feels this and finds the analogy rather more suitable for dementia praecox, which since Reil has frequently been compared to a dream.[42] The richness and acceleration of thought in manic flight of ideas can be sharply differentiated from the sluggish, often halting course of association in the dreamy type, and particularly from the poverty of associations in catatonics, with their numerous perseverations. The analogy is correct only in so far as the directing idea is absent in all these cases;

in manics because all the ideas crowd into consciousness with marked acceleration and great intensity of feeling,[43] which probably accounts for the absence of attention.[44] In daydreaming there is no attention from the outset, and wherever this is absent the course of association must sink to the level of a dream-state, to a slow progression according to the laws of association and tending mainly towards similarity, contrast, coexistence, and verbal-motor combinations.[45] Abundant examples are furnished by daily self-observation or by attentively following a general conversation. As Pelletier shows, the associations in dementia praecox are constructed along similar lines. This can best be seen from an example:

> Je suis l’être, l’être ancien, le vieil Hêtre,[46] que l’on peut écrire avec un H. Je suis universel, primordial, divine, catholique, apostolique, Romaine.[47] L’eusses-tu cru, l’être tout cru, suprumu,[48] l’enfant Jésus.[48] Je m’appelle Paul, c’est un nom, ce n’est pas une négation,[48] on en connait la signification. …[48] Je suis éternel, immense, il n’y a ni haut ni bas, *fluctuat nec mergitur*, le petit bateau,[49] vous n’avez pas peur de tomber.[50]

[23] This example shows us very clearly the course of association in dementia praecox. It is very superficial and proceeds by way of numerous clang associations. The disintegration is so marked, however, that we can no longer compare it to normal daydreaming, but must compare it directly to a dream. Indeed, the conversations we have in dreams sound very like this;[51] Freud’s *The Interpretation of Dreams* gives numerous examples.

[24] In “The Associations of Normal Subjects” it was shown that reduced attention produces associations of a superficial type (verbal-motor combinations, clang associations, etc.), and that, conversely, from the occurrence of a superficial type one could always infer a disturbance of attention. Judging by our experimental proofs, Pelletier is therefore correct in attributing the superficial type of association in dementia praecox to a lowering of attention. She calls this lowering, in Janet’s words, an *abaissement du niveau mental*. What we can also see from her work is that the disturbance is once again traced back to the central problem of apperception.

[25] In particular, it is to be noted that she overlooks the phenomenon of perseveration, but on the other hand we are indebted to her for a valuable observation on the symbols and symbolic relationships that are so very common in dementia praecox. She says: “It is to be noted that the symbol plays a very great role in the productions of the insane. One meets it at every step in the

persecuted and the demented; this is due to the fact that the symbol is a very inferior form of thought. The symbol could be defined as the false perception of a relation of identity, or of very great analogy, between two objects which in reality are only vaguely analogous."[52]

[26] From this it is clear that Pelletier associates catatonic symbols with disturbed attention. This assumption is definitely supported by the fact that symbols have long been known as a usual phenomenon in daydreaming and dreams.

[27] The psychology of negativism, concerning which numerous publications are now available, is a subject in itself. It is certain that the symptoms of negativism should not be regarded as anything clear and definite. There are many forms and degrees of negativism which have not yet been clinically studied and analysed with the necessary accuracy. The division of negativism into an active and a passive form is understandable, since the most complicated psychological cases take the form of active resistance. If analysis were possible in these cases, it would frequently be found that there were very definite motives for the resistance, and it would then be doubtful whether one could still talk of negativism. In the passive form, too, there are many cases that are difficult to interpret. Nevertheless there are plenty of cases where it is perfectly apparent that even simple processes of volition are invariably turned into their opposite. In our view, negativism always depends ultimately on negative associations. Whether there is also a negativism that is enacted in the spinal cord I do not know. The broadest view on the question of negativism is the one taken by Bleuler,[53] who shows that "negative suggestibility," or the compulsion to produce contrary associations, is not only a constituent of the normal psyche but a frequent mechanism of pathological symptoms in hysteria, obsessional states, and dementia praecox. The contrary mechanism is a function existing independently of the normal associative activity and is rooted entirely in "affectivity"; hence it is actuated chiefly by strongly feeling-toned ideas, decisions, etc. "The mechanism is meant to guard against precipitate action and to force one to weigh the pros and cons." The contrary mechanism acts as a counterbalance to suggestibility. Suggestibility is the capacity to accept and put into effect strongly feeling-toned ideas; the contrary mechanism does just the opposite. Bleuler's term "negative suggestibility" is therefore fitting. The close connection of these two functions makes it easier to understand why they are found together clinically. (Suggestibility side by side with insuperable contrary auto-suggestions in hysteria, and with negativism, command automatism, and echopraxia in dementia praecox.)

[28] The importance of negative suggestibility for the everyday life of the psyche explains why contrary associations are so extraordinarily frequent: they are the nearest to hand.[54]

[29] In language, too, we find something similar: the words that express common contrasts are very firmly associated and generally come into the category of well-worn verbal combinations (black-white, etc.). In primitive languages there is sometimes a single word for contrary ideas. In Bleuler's sense, therefore, only a relatively slight disturbance of feeling is needed to produce negativistic phenomena. As Janet has shown,[55] in obsessional personalities the *abaissement du niveau mental* is enough to release the play of contraries. What, then, are we to expect from the "apperceptive deterioration" in dementia praecox! And here we really do find that apparently uncontrolled play of positive and negative which is very often nicely reflected in verbal associations.[56] Hence, on the question of negativism there is no lack of grounds for the hypothesis that this symptom, too, is closely connected with "apperceptive deterioration." The central control of the psyche has become so weak that it can neither promote the positive nor inhibit the negative acts, or vice versa.[57]

[30] To recapitulate what we have said so far: The authors mentioned have established in the main that the lowering of attention—or, more generally speaking, "apperceptive deterioration" (Weygandt)—is a characteristic of dementia praecox. To this characteristic the peculiar superficiality of associations, the symbols, stereotypies, perseverations, command automatisms, apathy, aboulia, disturbance of reproduction and, in a limited sense, negativism, are all in principle due.

[31] The fact that comprehension and retention are not as a rule affected by the general deterioration may seem rather strange at first glance. One often finds in dementia praecox, during accessible moments, a surprisingly good, almost photographic memory, which by preference takes note of the most ordinary things that invariably escape the notice of normal persons.[58] But it is just this peculiarity that shows what kind of memory it is: it is nothing but a passive registration of events occurring in the immediate environment. Everything which requires an effort of attention passes unheeded by the patient, or at most is registered on the same level as the daily visit of the doctor or the arrival of dinner—or so at least it appears. Weygandt has given an excellent description of this lack of active assimilation. Comprehension is usually disturbed only during periods of excitement. Comprehension and retention are for the most part only

passive processes which occur in us without much expenditure of energy, just like seeing and hearing when these are not accompanied by attention.

[32] Although the above-mentioned symptoms (automatism, stereotypy, etc.) are to some extent deducible from Weygandt's conception of apperceptive deterioration, it does not suffice to explain the individual variety of the symptoms, their capriciousness, the peculiar content of the delusions, hallucinations, etc. Several investigators have attempted to solve this riddle.

[33] Stransky[59] has investigated the problem of dementia praecox from the clinical side. Starting from Kraepelin's conception of "emotional deterioration," he finds that two things are to be understood by this term: "First, the poverty or superficiality of emotional reactions; second, their incongruity with the ideational content dominating the psyche at the time."[60] Stransky thus differentiates Kraepelin's conception, and especially emphasizes that "emotional deterioration" is not the only thing one meets with clinically. The striking incongruity between idea and affect which we observe daily in dementia praecox is a commoner symptom at the onset of the disease than is the emotional deterioration. This incongruity obliges Stransky to assume two distinct psychic factors, the *noöpsyche* and the *thymopsyche*, the former comprising all purely intellectual and the latter all affective processes. These two concepts correspond by and large to Schopenhauer's intellect and will. In the healthy psyche there is naturally a constant, very delicately co-ordinated interaction of the two factors. But as soon as incongruity appears, this corresponds to *ataxia*, and we then have the picture of dementia praecox with its disproportionate and incomprehensible affects. To that extent the division of the psychic functions into noöpsyche and thymopsyche agrees with reality. But we must ask whether a quite ordinary content that appears in the patient with tremendous affect seems incongruous not merely to us, who have only a very imperfect insight into his psyche, but also to the subjective feeling of the patient.

[34] I will make this question clear by an example. I visit a gentleman in his office. Suddenly he starts up in a rage and swears most excitedly at a clerk who has just put a newspaper on the right instead of the left side of the table. I am astounded and make a mental note about the peculiar nervousness of this person. Afterwards I learn from another employee that the clerk has made the same mistake dozens of times before, so that the gentleman's anger was quite appropriate.

[35] Had I not received the subsequent explanation, I should have formed a wrong picture of the psychology of this person. We are frequently confronted with a similar situation in dementia praecox: owing to the peculiar “shut-in” state of the patients we see into them far too little, a fact which every psychiatrist will confirm. It is therefore very possible that their excitements often remain incomprehensible to us only because we do not see their associative causes. The same thing may also happen to us: we can be in a bad humour for a time, and quite inappropriately so, without being aware of the cause. We snap out answers in an unduly emphatic and irritated tone of voice, etc. If even the normal person is not always clear about the causes of his own bad temper, how much less can we be so in regard to the psyche of a dementia praecox patient! Owing to the obvious inadequacy of our psychological diagnosis we must be very cautious about assuming a real incongruity in Stransky’s sense of the term. Although clinically speaking an incongruity is often present, it is by no means limited to dementia praecox. In hysteria, too, it is an everyday occurrence; it can be seen in the very commonplace fact of hysterical “exaggerations.” The counterpart of this is the well-known *belle indifférence* of hysterics. We also find violent excitements over nothing, or rather over something that seems to have absolutely no connection with the excitement. Psychoanalysis, however, uncovers the motive, and we are beginning to understand why the patients react as they do. In dementia praecox we are at present unable to penetrate deeply enough, so that the connections remain unknown to us and we assume an “ataxia” between noöpsyche and thymopsyche. Thanks to analysis we know that in hysteria there is no “ataxia” but merely an oversensitiveness, which becomes clear and intelligible as soon as we discover the pathogenic complex of ideas.[61] Knowing how the incongruity comes about in hysteria, is it still necessary for us to assume a totally new mechanism in dementia praecox? In general we know far too little about the psychology of the normal and the hysterical[62] to dare to assume, in so baffling a disease as dementia praecox, completely new mechanisms unknown to all psychology. We should be sparing with new principles of explanation; for this reason I decline to accept Stransky’s hypothesis, clear and ingenious though it is.

[36] To make up for this, we have a very fine experimental work of Stransky’s[63] which provides a basis for the understanding of one important symptom, namely the speech confusion.

[37] Speech confusion is a product of the basic psychological disturbance. (Stransky calls it “intrapsychic ataxia.”) Whenever the relations between emotional life and ideation are disturbed, as in dementia praecox, and the orientation of normal thought by a directing idea (Liepmann) is lacking, a thought-process akin to flight of ideas is bound to develop. (As Pelletier has shown, the laws of association are stronger than the influence of the directing idea.) In the case of a-verbal process there will be an increase in the purely superficial connective elements (verbal-motor associations and clang reactions), as was shown in our experiments with distracted attention. Hand in hand with this there is a decrease in meaningful combinations. In addition, there are other disturbances such as an increased number of mediate associations, senseless reactions, repetitions of the stimulus word (often many times). Perseverations show contradictory behaviour under distraction; in our experiments they increase in women and decrease in men. In very many cases we could explain the perseveration by the presence of a strong feeling-tone: the strongly feeling-toned idea shows a tendency to perseverate. Everyday experience confirms this. Distraction of attention creates a sort of vacuum of consciousness[64] in which ideas can perseverate more easily than during full attention.

[38] Stransky then examined how continuous sequences of verbal associations behave under the influence of relaxed attention. His subjects had to talk at random into a phonograph for one minute, saying just what came into their heads. At the same time they were not to pay attention to what they said. A stimulus-word was given as a starting point. (In half the experiments an external distraction was also provided.)

[39] These tests brought interesting results to light: The sequence of words and sentences immediately recalled the talk (as well as the fragments of writing) we find in dementia praecox! A definite direction for the talk was ruled out by the way the experiment was conducted; the stimulus word acted for only a very short time as a more or less indefinite “theme.” Superficial connective elements predominated strikingly (reflecting the breakdown of logical connections), there were masses of perseverations (or else repetitions of the preceding word, which amounts roughly to the repetition of the stimulus word in our experiment); besides this there were numerous contaminations,[65] and closely connected with them neologisms, new word-formations.

[40] From Stransky’s voluminous material I should like to quote a few examples by way of illustration:

> The storks stand on one leg, they have wives, they have children, they are the ones that bring children, the children whom they bring home, of this home, an idea that people have about storks, about the activity of storks, storks are large birds, with a long beak and live on frogs, frogs, fresh frigs, the frigs are frugs first thing, first thing in the morning [*Früh*], fresh for breakfast [*Frühstück*], coffee, and with coffee they also drink cognac, and cognac they also drink wine, and with wine they drink everything possible, the frogs are large animals and which the frogs feed on, the storks feed on the fowls, the fowls feed on the animals, the animals are large, the animals are small, the animals are men, the animals are not men [etc., etc.].
>
> These sheep are … were merino sheep, from which the fat was cut by the pound, with Shylock the fat was cut, the pound was cut [etc.].
>
> K … was a K … with a long nose, with a ram's nose, with a ramp nose, with a nose to ram with, rambane, a man who has rammed, who is rammed [etc.].

[41] From these examples of Stransky's one can see at once what laws of association the thought-process follows: it is chiefly the laws of similarity, coexistence, verbal-motor combination, and combination according to sound. Besides that the numerous perseverations and repetitions (Sommer's "stereotypies") leap to the eye. If we compare this with the sample of dementia praecox associations quoted earlier from Pelletier, we shall find a striking resemblance[66]—in both cases the same laws of similarity, contiguity, and assonance. Only stereotypies[67] and perseverations are lacking in Pelletier's analysis, although they can plainly be seen in the material. Stransky then proceeds to document this obvious similarity with a number of excellent examples taken from dementia praecox.

[42] It is especially worth noting that in Stransky's tests with normal persons numerous conglomerations of words or sentences occur which can be described as contaminations. For example:

> … especially a meat one cannot get rid of, the thoughts one cannot get rid of, especially when one ought to persevere at it, persevere, sever, Severin [etc.].

[43] According to Stransky the following series of ideas are condensed in this conglomerate:

a. A lot of mutton is consumed in England.
b. I cannot get rid of this idea.
c. This is perseveration.
d. I ought to say at random what comes into my mind.

[44] Contamination is therefore a condensation of different ideas, and hence should be regarded in principle as an *indirect association*.[68] This quality of contamination is immediately apparent from the pathological examples given by Stransky:

Q: What is a mammal?

A: It is a cow, for instance a midwife.

[45] “Midwife” is an indirect association to “cow” and reveals the probable train of thought: *cow—bears living young—so do human beings—midwife*.[69]

Q: What do you understand by the Blessed Virgin?

A: The behaviour of a young lady.

[46] As Stransky rightly observes, the train of thought probably runs as follows: *immaculate conception—virgo intacta—chaste conduct*.

Q: What is a square?

A: An angular quadrate.

The condensation consists of:

a. A square is a quadrate.

b. A square has four angles.

[47] From these examples it should be clear that the numerous contaminations occurring under distracted attention are somewhat similar to the indirect associations which occur under distraction in simple word reactions. Our experiments have proved statistically the increase of indirect associations under distraction.

[48] This concurrence of three experimenters—Stransky, myself, and, so to speak, dementia praecox—can be no accident. It proves the correctness of our views and is yet another confirmation of the apperceptive weakness, the most striking of all the degenerative symptoms in dementia praecox.

[49] Stransky points out that contamination often produces strange word-formations, which are so bizarre that they immediately bring to mind the neologisms of dementia praecox. I am convinced that a great number of neologisms do come about in this way. A young patient who wanted to convince me of her normality once exclaimed: “Of course I am normal. It’s as broad as daylight!” She repeated this emphatically several times. The formation has the following components:

a. As clear as daylight,

b. In broad daylight.

[50] In 1898 Neisser,[70] on the basis of clinical observations, remarked that the new word-formations, which as a rule, like the verbal roots themselves, are neither verbs nor nouns, are not really words at all but represent sentences, since

they always serve to illustrate an entire process. This expression of Neisser's hints at the idea of condensation. But Neisser goes even further and speaks directly of the illustration of an entire process. At this point I would remind the reader that Freud in *The Interpretation of Dreams* has shown that a dream is a condensation[71] in the grand manner. Unfortunately I cannot discuss in detail the comprehensive and extremely valuable psychological material adduced by this still too little appreciated investigator; it would lead us much too far afield. I must simply take a knowledge of this important book for granted. So far as I know, no real refutation of Freud's views has yet been made. Hence I shall confine myself to affirming that dreams, which in any case have numerous analogies with the associative disturbances in dementia praecox, also show the special speech-condensations consisting of the contamination of whole sentences and situations. Kraepelin, too, was struck by the resemblance between the language of dreams and that of dementia praecox.[72] From the numerous examples I have observed in my own and other people's dreams I will select only a very simple one. It is at once a condensation and a neologism. Wishing to express approval of a certain situation in a dream, the dreamer remarks: "That is fimous"—a condensation of "fine" and "famous."

[51] Dreams are an "apperceptive" weakness par excellence, as is particularly clear from their well-known predilection for *symbols*.[73]

[52] Finally, there is one more question which should really have been answered first, and that is: Does the state of consciousness in Stransky's experiments conducted under normal conditions really correspond to one of disturbed attention? Above all it should be noted that his distraction experiments show no essential changes compared with the normal experiments; consequently neither association nor attention can have been so very different in the two states. But what is one to think of the disturbance in the normal experiments?

[53] It seems to me that the main reason is to be sought in the "forced" character of the experiment. The subjects were told to talk at random, and that they sometimes did so with great rapidity is proved by the fact that on average they uttered 100 to 250 words per minute, whereas in normal speech the average per minute is only 130 to 140.[74] Now if a person talks more quickly and perhaps thinks more quickly than he is accustomed to do about ordinary and indifferent things, he cannot pay sufficient attention to his associations. A second point that needs to be considered is this: for the great majority of the subjects the situation was an unusual one and must have influenced their emotional state. They were in the position of an excited orator who gets into a state of "emotional

stupidity."[75] In such conditions I found an extraordinarily high number of perseverations and repetitions. But emotional stupidity likewise causes great disturbance of attention. We can therefore take it as certain that in Stransky's normal experiments attention really was disturbed, though the actual state of consciousness is far from clear.

[54] We are indebted to Heilbronner[76] for an important observation. Examining a series of associations in a case of hebephrenia, he found that on one occasion 41%, and on another 23%, of the reaction-words referred to the environment. Heilbronner considers this as proving that the fixation originates in the "vacuum," i.e., is due to the lack of new ideas. I can confirm this observation from my own experience. Theoretically, it would be interesting to know how this symptom is related to the Sommer-Leupoldt symptom of "naming and touching."

[55] New and independent views on the psychology of dementia praecox are expressed by Otto Gross.[77] He proposes *dementia sejunctiva* as a name for the disease, the reason being the disintegration or "sejunction" of consciousness. The concept of sejunction is, of course, taken from Wernicke; Gross could just as well have taken the much older, synonymous concept of dissociation from Binet and Janet. Fundamentally, dissociation of consciousness means the same thing as Gross's sejunction of consciousness. The latter term only gives us another new word, of which we have more than enough in psychiatry already. By dissociation the French school meant a weakening of consciousness due to the splitting off of one or more sequences of ideas; they separate themselves from the hierarchy of ego-consciousness and begin to lead a more or less independent existence of their own.[78] The Breuer-Freud theory of hysteria grew up on this basis. According to the more recent formulations of Janet, dissociation is the result of the *abaissement du niveau mental,* which destroys the hierarchy and promotes, or actually causes, the formation of automatisms.[79] Breuer and Freud have shown very nicely what kind of automatisms are then released.[80] Gross's application of this theory to dementia praecox is new and important. Writing of his basic idea, the author says: "Disintegration of consciousness in my sense of the word means the simultaneous occurrence of functionally discrete chains of association. … For me the main point lies in the view that the conscious activity of the moment is the result of many psychophysical processes occurring synchronously."[81]

[56] These two quotations may be sufficient to illustrate the author's concept. We can perhaps agree with the view that consciousness, or rather, the content of

consciousness, is the outcome of countless non-conscious (or unconscious) psychophysical processes. Compared with the current psychology of consciousness, which holds that at the point where the epiphenomenon “consciousness” leaves off the nutritive processes of the brain cells immediately begin, this view represents a refreshing advance for psychiatry. Gross evidently visualizes the *psychic content* (not the content of consciousness) as separate chains of association occurring simultaneously. I think this simile is rather misleading: it would seem to me more correct to assume complexes of ideas which become conscious successively and are constellated by previously associated complexes. The cement binding these complexes together is some definite affect.[82] If the connection between Gross’s synchronous chains of association is loosened by the disease, a disintegration of consciousness sets in. In the language of the French school, this means that when one or more sequences of ideas split off, there is a dissociation which causes a weakening of consciousness. Let us not quarrel about words, however. Here Gross comes back to the problem of apperceptive disturbance, but he approaches it from a new and interesting angle—from the side of the unconscious. He makes the attempt to uncover the roots of the numerous automatic phenomena which burst into the consciousness of the dementia praecox patient with elemental force and strangeness. The signs of automatic phenomena in the conscious life of the patient should be known to every psychiatrist: they are the “autochthonous” ideas, sudden impulses, hallucinations, influencing of thought, obsessive sequences of strange ideas, stoppage and disappearance of thought (aptly termed by one of my patients “thought deprivation”), inspirations, pathological ideas, etc.

[57] Gross states that the catatonic symptoms are

> alterations of the will itself by an agent felt as external to the continuity of the ego and therefore interpreted as a strange power. [They are] a momentary replacement of the continuity of the ego’s will by the intrusion of another chain of consciousness. … We have to imagine that several chains of association can be maintained in the organ of consciousness simultaneously, without influencing one another. One of these chains will have to become the carrier of the continuity of consciousness … the other chains of association will then naturally be “subconscious” or, better, “unconscious.” Now at any given time it must be possible for, let us say, the nervous energy in them to mount up and reach such a pitch that attention is suddenly directed to one of the terminal links in the chain, so that a link from an unconscious chain of associations

unexpectedly forces itself directly into the continuity of the hitherto dominant chain. If these conditions are fulfilled, the accompanying subjective process can only be such that any psychic manifestation is felt as suddenly irrupting into consciousness and as something entirely foreign to its continuity. The explanatory idea will then follow almost inevitably that this particular psychic manifestation did not come from one's own organ of consciousness but was injected into it from outside.[83]

[58] As I have said, the displeasing thing about this hypothesis is the assumption of independent but synchronous chains of association. Normal psychology furnishes nothing in support of this. In hysteria, where we can best examine split-off sequences of ideas, we find that the opposite holds true. Even when we are apparently dealing with totally distinct sequences, we can find somewhere, in a hidden place, the bridge leading from one to the other.[84] In the psyche everything is connected with everything else: the existing psyche is the resultant of myriads of different constellations.

[59] But apart from this slight defect, I think we may call Gross's hypothesis a singularly happy one. It tells us, in short, that the roots of all automatic phenomena lie in the unconscious bonds of association. When consciousness "disintegrates" (*abaissement du niveau mental*, apperceptive weakness), the complexes coexisting with it are simultaneously freed from all restraint and are then able to break through into ego-consciousness. This is an eminently psychological conception and is clearly in accord with the teachings of the French school, with our experience of hypnotism, and with the analysis of hysteria. If we depotentiate consciousness by suggestion and thus produce a split-off complex of ideas, as in a post-hypnotic command, this split-off complex will break through into ego-consciousness with inexplicable force. In the psychology of ecstatic somnambulists we find the same typical irruptions of split-off ideas.[85]

[60] Unfortunately Gross leaves one question open, and that is: Exactly what are these split-off sequences of ideas and what is the nature of their content?

[61] Sometime before Gross wrote anything, Freud answered this question in a very brilliant way. As far back as 1893 Freud showed[86] how a hallucinatory delirium arises from an affect which is intolerable to consciousness, how this delirium is a compensation for unsatisfied wishes, and how the individual takes refuge, as it were, in the psychosis in order to find in the dreamlike delirium of the disease what is denied him in reality. In 1896 Freud analysed a paranoid illness, one of Kraepelin's paranoid forms of dementia praecox, and showed

how the symptoms are determined exactly in accordance with the transformation mechanisms in hysteria. Freud said at the time that paranoia, or the group of illnesses included under paranoia, is also a defence neuropsychosis; that it arises, like hysteria and obsessional ideas, from the repression of painful reminiscences, and that its symptoms are determined by the content of the repression.[87]

[62] In view of the far-reaching significance of such an hypothesis it is worth while to go more closely into this classic analysis of Freud's.

[63] The case[88] is that of a 32-year-old woman who manifested the following symptoms: She imagined that her environment had changed, she was no longer respected, people insulted her, she was watched, her thoughts were known. Later she got the idea that she was watched in the evening while undressing; then she experienced sensations in her abdomen which she believed were caused by an indecent thought on the part of the servant girl. Visions then appeared in which she saw female and male genitals. Whenever she was alone with women she had hallucinations of female genitals, and at the same time felt as though the other women could see hers.

[64] Freud analysed this case. He found that this patient behaved just like an hysteric; that is, she showed the same resistances, etc. What seemed unusual was that the repressed thoughts did not appear, as in hysteria, in the form of loosely connected fancies, but in the form of inner hallucinations; she therefore compared them to her voices. (Later I shall have occasion to furnish experimental proof of this observation.) The hallucinations began after the patient had seen a number of female patients naked in the bathing-room.[89] "It was to be presumed that [this impression] had been repeated only because great interest had been taken in it. She then said she had at the time felt shame for those women." This somewhat compulsive, altruistic shame was striking, and pointed to something repressed. The patient then reproduced "a series of scenes from her seventeenth back to her eighth year in which she had been ashamed of her nakedness in the presence of her mother while bathing, her sister, or the family physician; the series … ended in a scene in her sixth year, in which she undressed in the nursery on going to bed without feeling shame about her brother's presence." Finally it turned out that "the brother and sister had for years had the habit of showing themselves to each other naked before going to bed." On those occasions she was not ashamed. "She was now making up for the shame which she had not felt as a child."

[65] The beginning of her depression occurred at the time of a quarrel between her husband and her brother in consequence of which the latter no longer came to the house. She had always been very fond of this brother. … Further, she also referred to a certain period in her illness at which for the first time “everything became clear to her”—that is to say, the time when she became convinced of the truth of her conjecture that she was being generally scorned and deliberately insulted. This certainty came upon her during a visit from a sister-in-law, who in the course of conversation remarked casually, “If anything of that kind happened to me I should simply shrug my shoulders.” Frau P. at first received this remark with indifference, but later, after the visitor had left, it occurred to her that the words contained a reproach, as if *she* was wont to make light of serious things; and from that moment she felt sure that she was the victim of universal slander. When I questioned her why she felt justified in applying these words to herself, she replied that it was the tone in which her sister-in-law had spoken which (although only later) had convinced her of it—a characteristically paranoiac detail. I now urged her to recollect the remarks which her sister-in-law had made *before* the expression complained of, and I learnt that the sister-in-law had related that in her home there had been all sorts of difficulties with her *brothers,* and had added the wise comment: “In every family things occur over which one would gladly draw a veil, but if anything of the kind happened to me I should think nothing of it.” Frau P. now had to admit that her depression was related to these sentences before the last remark. Since she had repressed both of the sentences which might have aroused the memory of her relations with her brother and had retained in memory only the insignificant last sentence, she had had to connect her idea that her sister-in-law was intending a reproach against her with this last sentence; and as its contents offered no support to this interpretation she turned from the contents to the *tone* in which the words were spoken.

[66] After this explanation Freud turned his attention to the analysis of the voices. “In the first place it had to be explained why such an indifferent content as ‘Here comes Frau P.,’ ‘She’s looking for a house now,’ and the like, could be so distressing to her.” She first heard the voices after she had read a novel by O. Ludwig, called *Die Heiterethei*. After reading it she went for a walk on a country road, and suddenly while passing a peasant’s cottage the voices told her: “That’s what Heiterethei’s house looked like! There’s the spring and there’s the shrubbery! How happy she was in spite of all her poverty!” Then the voices repeated to her whole paragraphs from the book she had just read, although the content was of no importance.

[67] The analysis showed that during her reading her mind had wandered and she had become excited by totally different passages in the book. Against this material—analogies between the couple in the novel and herself and her husband, memories of intimacies in her married life and family secrets—there arose a repressing resistance, because it was connected by easily demonstrable trains of thought with her sexual dread and finally amounted to an awakening of the old childhood experience. In consequence of the censorship exercised by the repression, the harmless and idyllic passages, which were connected with the proscribed ones by contrast and also by proximity, became strengthened in consciousness and were able to "say themselves aloud." The first of the repressed ideas, for instance, related to the gossip among the neighbours to which the heroine, who lived all alone, was exposed. She easily discovered the analogy with herself in this; she also lived in a small place, saw no one, and thought herself despised by her neighbours. This distrust of her neighbours had a foundation in real experience; for when she was first married she had at first been obliged to be content with a small dwelling, and the wall of the bedroom against which the bed of the young couple stood adjoined a room of the neighbours. Great sexual shyness first awoke in her at the time of her marriage—obviously by its arousing memories of the affair in her childhood when the two children played at man and wife; she was continually apprehensive lest the neighbours should distinguish words and noises through the intervening wall, and this shame turned itself into suspicions of the neighbours in her mind.

[68] On further analysis of the voices Freud often found "the character of diplomatic indefiniteness; the distressing allusion was usually closely hidden, the connection between the particular sentences being disguised by a strange tone of voice, unusual forms of speech, and the like—characteristics common to the auditory hallucinations of paranoiacs and in which I see traces of the compromise-distortion."

[69] I have purposely given the floor to the author of this first analysis of paranoia, which is so extremely important for psycho-pathology, because I did not know how to abridge Freud's ingenious argument.

[70] Let us now turn back to the question concerning the nature of the dissociated ideas. We can now see what meaning Freud attaches to Gross's supposed dissociations: they are nothing other than repressed complexes as found in hysterics[90] and—last but not least—in normal persons.[91] The secret of the repressed ideas turns out to be a psychological mechanism of general significance, and a quite ordinary occurrence. Freud sheds new light on the

question of incongruity between the content of consciousness and feeling-tone discussed by Stransky. He shows how indifferent and quite trivial ideas may be accompanied by an intense feeling-tone, which, however, has been taken over from a repressed idea. Here Freud opens the way to understanding the inadequate feeling-tone in dementia praecox. I need hardly discuss the significance of this.

[71] The results of Freud's investigations may be summed up as follows. Both in their form and content, the symptoms of paranoid dementia praecox express thoughts which, in consequence of their painful feeling-tone, became incompatible with the ego-consciousness and were therefore repressed. These repressions determine the nature of the delusions and hallucinations, as well as the general behaviour of the patient. Hence, whenever an apperceptive paralysis appears, the resultant automatisms contain the split-off complexes of ideas—the whole army of bottled-up thoughts is let loose. Thus we may generalize the conclusions reached by Freud's analysis.

[72] Uninfluenced by Freud, Tiling[92] came to very similar conclusions on the basis of clinical experience. He, too, would like to attribute to the individual an almost incalculable significance as regards the origin and specific form of the psychosis. The importance of the individual factor, and of the individual's psychology in general, is undoubtedly underestimated in modern psychiatry, less perhaps for theoretical reasons than because of the helplessness of the practising psychologist. We can therefore go a long way with Tiling, at any rate a good deal further than Neisser[93] thought he could go. But on the question of aetiology, the core of the problem, we must make a halt. According neither to Freud nor to Tiling does the individual psychology explain the origin of the psychosis. This can be seen most clearly in Freud's analysis, quoted above. The "hysterical" mechanisms he uncovered suffice to explain the origin of *hysteria*, but why then does *dementia praecox* arise? We can understand why the content of the delusions and hallucinations is so and not otherwise, but why *non-hysterical* delusions and hallucinations should appear at all we do not know. There may be an underlying *physical* cause that overrides all psychological causes. Let us further assume with Freud that every paranoid form of dementia praecox follows the mechanism of hysteria—but why is it that paranoia is uncommonly stable and resistant, while hysteria is characterized by the great mobility of its symptoms?

[73] Here we come upon a new factor in the disease. The mobility of the hysterical symptoms is due to the mobility of affects, while paranoia is

characterized by fixation of affects, as Neisser says.[94] This idea, which is extraordinarily important for the theory of dementia praecox, is formulated by Neisser[95] as follows:

> Only a very slight assimilation takes place from the outside. The patient is able to exert less and less influence on the course of his ideas, and in this way, to a much greater extent than in the normal, there arise separate groups of ideational complexes. Their contents are bound together only by the personal relationship attaching to them all; apart from this they are not fused in any other way, and, depending on the constellation of the moment, now one and now another of these complexes will determine the course of psychic elaboration and association. Thus a gradual decay of the personality sets in; it becomes, as it were, a passive spectator of the impressions flowing in from the various internal sources of stimulation, a lifeless plaything of the excitations generated by them. The affects which are normally meant to regulate our relations with the surrounding world and to implement our adaptation to it—which act, indeed, as a means of protecting the organism and are the motive forces of self-preservation—these affects become alienated from their natural purpose. The strong organically determined feeling-tone of the delusional trains of thought brings it about that, no matter what the emotional excitation may be, these and these only are reproduced, over and over again. This fixation of affects destroys the capacity to feel joy and compassion, and leads to the emotional isolation of the patients, which runs parallel with their intellectual alienation.

[74] Neisser has here described the familiar picture of apperceptive deterioration: lack of new ideas, paralysis of all purposive progress adapted to reality, decay of the personality, autonomy of complexes. To these he adds the "fixation of affects," that is, the fixation of the feeling-toned complexes of ideas. (Affects usually have an intellectual content, though it need not always be conscious.) This explains the emotional impoverishment (for which Masselon coined the apt expression "coagulation"). Fixation of affects therefore means, in Freudian terms, that the repressed complexes (the carriers of affects) can no longer be eliminated from the conscious process; they remain operative, and so prevent the further development of personality.

[75] In order to prevent misunderstandings, I must add at once that the continued predominance of a strong complex in normal psychic life can lead merely to hysteria. But the symptoms produced by the hysterogenic affect are different from those of dementia praecox. We must therefore suppose that the disposition for the origin of dementia praecox is quite different from that for hysteria. If a

purely hypothetical conjecture may be permitted, we might venture the following train of thought: the hysterogenic complex produces reparable symptoms, while the affect in dementia praecox favours the appearance of anomalies in the metabolism—toxins, perhaps, which injure the brain in a more or less irreparable manner, so that the highest psychic functions become paralysed. As a result, the acquisition of new complexes is slowed down or ceases altogether; the pathogenic (or rather, the precipitating) complex remains the last one, and the further development of the personality is finally checked. In spite of an apparently uninterrupted causal chain of psychological events leading from the normal to the pathological, we should never overlook the possibility that in certain cases a change in the metabolism (in Kraepelin's sense) may be primary; the complex which happens to be the newest and last one "coagulates" and determines the content of the symptoms. Our experience does not yet go nearly far enough to warrant the exclusion of such a possibility.

Summary

[76] This anthology from the literature shows very clearly, in my opinion, how all these views and researches, though apparently having hardly any connection with one another, nevertheless converge towards the same goal. The observations and suggestions culled from the many different domains of dementia praecox point above all to the idea of a quite central disturbance, which is called by various names: apperceptive deterioration (Weygandt); dissociation, *abaissement du niveau mental* (Masselon, Janet); disintegration of consciousness (Gross); disintegration of personality (Neisser and others). Then, the tendency to fixation is stressed (Masselon, Neisser), and from it Neisser derives the emotional impoverishment. Freud and Gross lay their finger on the important fact of the existence of split-off ideas, and to Freud belongs the merit of having been the first to demonstrate the "principle of conversion" (repression and indirect reappearance of complexes) in a case of paranoid dementia praecox. Nevertheless, the mechanisms of Freud are not comprehensive enough to explain why dementia praecox arises and not hysteria; we must therefore postulate for dementia praecox a specific concomitant of the affect—toxins?—which causes the final fixation of the complex and injures the psychic functions as a whole. The possibility that this "intoxication" might be due primarily to somatic causes, and might then seize upon the last complex which happened to be there and pathologically transform it, should not be dismissed.

2. THE FEELING-TONED COMPLEX AND ITS GENERAL EFFECTS ON THE PSYCHE

[77] My theoretical premises for an understanding of the psychology of dementia praecox are, in principle, exhausted with the contents of the first chapter, for Freud has, strictly speaking, said all that is essential in his works on hysteria, obsessional neurosis, and dreams. Nevertheless our concepts, worked out on an experimental basis, differ somewhat from those of Freud, and it may be that the concept of the feeling-toned complex goes a little beyond the scope of Freud's views.

[78] The essential basis of our personality is affectivity.[1] Thought and action are, as it were, only symptoms of affectivity.[2] The elements of psychic life, sensations, ideas, and feelings, are given to consciousness in the form of certain units, which can perhaps be compared—if one may risk a chemical analogy—to molecules.

[79] For example: I meet an old friend in the street, and immediately there is formed in my brain an image, a functional unit: the image of my friend X. In this unit, or "molecule," we can distinguish three components, or "radicals": sense-perception, intellectual components (ideas, memory-images, judgments, etc.), and feeling-tone.[3] These three components are firmly united, so that if the memory-image of X rises to the surface all the elements belonging to it usually come with it, too. (Sense-perception is represented by a simultaneous, centrifugal excitation of the sensory spheres concerned.) I am therefore justified in speaking of a functional unit.

[80] Now, through the thoughtless gossip of my friend X, I once became involved in a very unpleasant affair and had to suffer the consequences for a long time. This affair comprises a large number of associations (it may be compared to a body made up of countless molecules); many persons, things, and events are included in it. The functional unit, "my friend," is only one of many figures. The entire mass of memories has a definite feeling-tone, a lively feeling of *irritation*. Every molecule participates in this feeling-tone, so that, whether it appears by itself or in conjunction with others, it always carries this feeling-tone with it, and it does this with the greater distinctness the more distinctly we can see its connection with the complex-situation as a whole.[4]

[81] I once witnessed the following incident as an illustration of this: I was taking a walk with a very sensitive and hysterical gentleman. The village bells

were pealing a new and very harmonious chime. My companion, who usually displayed great feeling for such chimes, suddenly began to rail at it, saying he could not bear that disgusting ringing in the major key, it sounded frightful; moreover it was a hideous church and a squalid-looking village. (The village is famous for its charming situation.) This remarkable inappropriate affect interested me, and I pursued my investigations further. My companion then began to abuse the local parson. The reason he gave was that the parson had a repulsive beard and—wrote very bad poetry. My companion, too, was poetically inclined. Thus, the affect lay in poetic rivalry.

[82] This example shows how each molecule (bell-ringing, etc.) participates in the feeling-tone (poetic rivalry) of the whole fabric of ideas,[5] which we call the feeling-toned complex. Understood in this sense, the complex is a higher psychic unity. When we come to examine our psychic material (with the help of the association test, for example), we find that practically every association belongs to some complex or other.[6] To be sure, it is rather difficult to prove this in practice, but the more carefully we analyse them the more clearly we see the relation of the individual associations to complexes. Their relation to the *ego-complex* is beyond all doubt. The ego-complex in a normal person is the highest psychic authority. By this we mean the whole mass of ideas pertaining to the ego, which we think of as being accompanied by the powerful and ever-present feeling-tone of our own body.

[83] The feeling-tone is an affective state accompanied by somatic innervations. The ego is the psychological expression of the firmly associated combination of all body sensations. One’s own personality is therefore the firmest and strongest complex, and (good health permitting) it weathers all psychological storms. It is for this reason that the ideas which directly concern our own persons are always the most stable, and to us the most interesting; we could also express this by saying that they possess the strongest *attention-tone*. (“Attention” in the sense used by Bleuler is an affective state.[7])

Acute Effects of the Complex

[84] Reality sees to it that the peaceful cycle of egocentric ideas is constantly interrupted by ideas with a strong feeling-tone, that is, by affects. A situation threatening danger pushes aside the tranquil play of ideas and puts in their place a complex of other ideas with a very strong feeling-tone. The new complex then crowds everything else into the background. For the time being it is the most

distinct because it totally inhibits all other ideas; it permits only those egocentric ideas to exist which fit *its* situation, and under certain conditions it can suppress to the point of complete (momentary) unconsciousness all ideas that run counter to it, however strong they may be. It now possesses the strongest attention-tone. (Thus we should not say that we direct our attention to something, but that the state of attention sets in with this idea.[8])

[85] How does a complex get its inhibiting or stimulating power?

[86] We have seen that the ego-complex, by reason of its direct connection with bodily sensations, is the most stable and the richest in associations. Awareness of a threatening situation arouses fright. Fright is an affect, hence it is followed by bodily changes, by a complicated harmony of muscular tensions and excitations of the sympathetic nervous system. The perception has thus found the way to somatic innervation and thereby helped the complex associated with it to gain the upper hand. Through the fright, countless body sensations become altered, and in turn alter most of the sensations on which the normal ego is based. Consequently the normal ego loses its attention-tone (or its clarity, or its stimulating and inhibiting influence on other associations). It is compelled to give way to the other, stronger sensations connected with the new complex, yet normally it is not completely submerged but remains behind as an “affect-ego,”[9] because even very powerful affects cannot alter all the sensations lying at the base of the ego. As everyday experience shows, this affect-ego is a weak complex, greatly inferior to the affective complex in constellating power.

[87] Let us assume that the threatening situation passes rapidly: the complex soon loses some of its attention-tone, since the body sensations gradually resume their normal character. Nevertheless, in its physical as well as its psychic components, the affect goes on vibrating for some time afterwards; the knees shake, the heart continues to pound, the face is flushed or pale, “one can hardly recover from the fright.” From time to time, first at short and then at longer intervals, the fright-image returns, charged with new associations, and evokes re-echoing waves of affect. This perseveration of the affect, coupled with great intensity of feeling, is one reason for a corresponding increase in the richness of associations. Hence large complexes are always strongly feeling-toned and, conversely, strong affects always leave behind very large complexes. This is due simply to the fact that on the one hand large complexes include numerous somatic innervations, while on the other hand strong affects constellate a great many associations because of their powerful and persistent stimulation of the body. Normally, affects can go on working indefinitely (in the

form of stomach and heart troubles, insomnia, tremors, etc.). Gradually, however, they subside, the ideas relating to the complex disappear from consciousness, and only in dreams do they occasionally manifest themselves in more or less disguised hints. But complexes continue to show themselves for years in the characteristic disturbances they produce in a person’s associations. Their gradual extinction is marked by one general psychological peculiarity: their readiness to reappear in almost full strength as a result of similar though much weaker stimuli. For a long time afterwards there remains a condition which I would like to call “complex-sensitiveness.” A child once bitten by a dog will scream with terror at the mere sight of a dog in the distance. People who have received bad news will thereafter open all their mail with apprehension. These effects of the complex, which may last for a very long time, lead to a consideration of the—

Chronic Effects of the Complex

[88] Here we must distinguish two kinds:

1. An effect that continues over a very long period and is produced by an affect occurring only once.

2. Chronic effects which become permanent because the affect is in a continuous state of excitation.

[89] The first group is best illustrated by the legend of Ramón Lully, who, as a gallant adventurer, had long courted a lady. Finally the longed-for *billet* arrived, inviting him to a midnight assignation. Lully, full of expectation, came to the appointed place, and as he approached the lady, who was awaiting him, she suddenly threw open her robe and uncovered her cancereaten bosom. This episode made such an impression on Lully that from then on he devoted his life to pious asceticism.

[90] There are impressions which last a lifetime. The lasting effects of strong religious impressions or of shattering experiences are well known. The effects are particularly strong in youth. Indeed, the whole aim of education is to implant lasting complexes in the child. The durability of a complex is guaranteed by its continually active feeling-tone. If the feeling-tone is extinguished, the complex is extinguished with it. The persistence of a feeling-toned complex naturally has the same constellating effect on the rest of the psychic activities as an acute affect. Whatever suits the complex is assimilated, everything else is excluded or at least inhibited. The best examples of this can

be seen in religious convictions. There is no argument, no matter how threadbare, that is not advanced if it is *pro*, while on the other hand the strongest and most plausible arguments *contra* make no impression; they simply bounce off, because emotional inhibitions are stronger than all logic. Even in quite intelligent people who have considerable education and experience one can sometimes observe a real blindness, a true systematic anaesthesia, when one tries to convince them, say, of the theory of determinism. And how often does a single unpleasant impression produce in some people an unshakable false judgment, which no logic, no matter how cogent, can dislodge!

[91] The effects of the complex extend, however, not only to thought but to action, which is continually forced in a quite definite direction. For instance, many people unthinkingly perform religious rites and all kinds of groundless actions despite the fact that intellectually they have long since outgrown them.

[92] The second group of chronic effects, where the feeling-tone is constantly maintained by active stimuli, affords the best examples of complex constellations. The strongest and most lasting effects are seen above all in sexual complexes, where the feeling-tone is constantly maintained, for instance by unsatisfied sexual desire. A glance at the legends of the saints, or at Zola's novels *Lourdes* or *The Dream*, will provide numerous examples of this. Yet the constellations are not always quite so crude and obvious, often they are more subtle influences, masked by symbolisms, that sway our thoughts and actions. Here I must refer the reader to the numerous and instructive examples given by Freud. Freud puts forward the concept of "symptomatic action" as a special instance of constellation. (Actually one should speak of "symptomatic thought" as well as "symptomatic action.") In his *Psychopathology of Everyday Life* he shows how apparently accidental disturbances of our actions, such as slips of the tongue, misreading, forgetting, etc., are due to constellated complexes. In his *Interpretation of Dreams* he points out similar influences in our dreams. In our experimental work we have demonstrated that complexes disturb the association tests in a characteristic and regular manner (peculiar forms of reaction, perseveration, prolongation of reaction time, failure to react, forgetting of critical or post-critical reactions,[10] etc.).

[93] These observations give us valuable hints in regard to the theory of complexes. In selecting my stimulus-words I always took care to employ as far as possible ordinary words from everyday speech, in order to avoid intellectual difficulties. One would expect an educated person to react "smoothly" to the test, but as a matter of fact this is not so. At the simplest words hesitations and

other disturbances occur which can only be explained by the fact that the stimulus-word has hit a complex. But why cannot an idea which is closely associated with a complex be reproduced “smoothly”? The prime reason for the obstruction is emotional inhibition. Complexes are mostly in a state of repression because they are concerned as a rule with the most intimate secrets which are anxiously guarded and which the subject either will not or cannot divulge. Even under normal conditions the repression may be so strong that the subject has an hysterical amnesia for the complex; that is, he has the feeling that some idea, some significant association, is coming up, but a vague hesitation keeps the reproduction back. He feels he wants to say something, but it slips away again immediately. What has slipped away is the thought-complex. Occasionally a reaction comes which unconsciously contains this thought, but the subject is blind to it, and only the experimenter can put him on the right track. The repressive resistance also has a striking effect afterwards on the reproduction test: the critical and post-critical reactions are apt to be smitten with amnesia. These facts all indicate that the complex has an exceptional position compared with the more indifferent psychic material. Indifferent reactions come “smoothly” and generally have very short reaction times; they are always on hand for the ego complex to use as it pleases. Not so the complex reactions: they come only with a struggle, when about to appear they often slip away again from the ego-complex, their form is peculiar, as often they are embarrassing products and the ego itself does not know how it ever got hold of them, they are liable to amnesia immediately afterwards—unlike the indifferent reactions which often have great stability and can be reproduced unchanged even after months or years. The complex associations are therefore much less at the disposal of the ego-complex than the indifferent ones. From this we must conclude that the complex occupies a relatively independent position in regard to the ego-complex—a vassal that will not give unqualified allegiance to its rule. Experience also shows that the stronger the feeling-tone of a complex, the stronger and more frequent will be the disturbances of the experiment. A person with a strong feeling-toned complex is less able to react smoothly, not only to the association test but to all the stimuli of daily life, as he is continually hindered and disturbed by the uncontrollable influences of the complex. His self-control (control of his moods, thoughts, words, and deeds) suffers in proportion to the strength of the complex; the purposefulness of his actions is more and more replaced by unintentional errors, blunders, unpredictable lapses for which he himself can give no reason. A person with a strong complex therefore shows intensive disturbances during association tests because a large number of apparently innocent stimulus-words hit the complex. The following two examples will illustrate this.

[94] CASE 1. The stimulus-word “white” has numerous well-worn associations, but the patient could react only hesitantly with “black.” By way of explanation I obtained some more associations to “white.” “Snow is white, and so is the sheet covering the face of the dead.” The patient had recently lost a relative whom she loved. The well-worn contrast “black” suggests symbolically the same thing, i.e., mourning.

[95] CASE 2. “Paint” hesitantly aroused the reaction “landscapes.” This reaction was explained by the following train of associations: “One paints landscapes, portraits, faces—also the cheeks when one has wrinkles.” The patient, an old maid who lamented the loss of an admirer, bestowed a loving attention on her person (symptomatic action), thinking to make herself more attractive by painting her face. “One paints one’s face for play-acting, once I play-acted too.” It should be noted that she played in amateur theatricals at the time when she still had her lost lover.

[96] The associations of persons with strong complexes swarm with examples of this kind. But the association experiment reflects only one side of daily psychological life. The complex-sensitiveness can also be demonstrated in all the other psychic reactions, as shown in the following cases.

[97] CASE 1. A certain young lady could not bear to see the dust beaten out of her cloak. This peculiar reaction could be traced back to her masochistic disposition. As a child her father frequently chastised her on the buttocks, thus causing sexual excitation. Consequently she reacted to anything remotely resembling chastisement with marked rage, which rapidly passed over into sexual excitement and masturbation. Once, when I said to her casually, “Well, you have to obey,” she got into a state of marked sexual excitement.

[98] CASE 2. Mr. Y fell hopelessly in love with a lady who soon afterwards married Mr. X. Although Mr. Y had known Mr. X for a long time and even had business dealings with him, he again and again forgot his name, so that on a number of occasions he had to ask other people when he wished to correspond with Mr. X.

[99] CASE 3. A young hysteric was suddenly assaulted by her lover, and was especially frightened by the erect member of her seducer. Afterwards she became afflicted with a stiff arm.

[100] CASE 4. A young lady, while guilelessly telling me a dream, for no apparent reason suddenly hid her face behind a curtain in an ostentatious manner. Analysis of the dream revealed a sexual wish which fully explained the reaction of shame.[11]

[101] CASE 5. Many people commit extraordinarily complicated actions which at bottom are nothing but symbols for the complex. I know a young girl who likes to take a baby-carriage with her on her walks, because, as she blushingly admitted to me, she would then be taken for a married woman. Elderly unmarried women often use dogs and cats as complex-symbols.

[102] As these examples show, thought and action are constantly disturbed and distorted by a strong complex, in large things as in small. The ego-complex is, so to say, no longer the whole of the personality; side by side with it there exists another being, living its own life and hindering and disturbing the development of the ego-complex, for the symptomatic actions often take up a good deal of time and energy at its expense. So we can easily imagine how much the psyche is influenced when the complex gains in intensity. The clearest examples are always furnished by sexual complexes. Let us take for instance the classic state of being in love. The lover is obsessed by his complex: his whole interest hangs solely on this complex and on the things that suit it. Every word, every object reminds him of his beloved (in the association test even apparently quite indifferent stimulus words can hit the complex). The most trivial objects are guarded like priceless jewels, so far as they relate to the complex; his whole environment is viewed *sub specie amoris*. Anything that does not suit the complex simply glances off, all other interests sink to nothing, there is a standstill and temporary atrophy of the personality. Only what suits the complex arouses affects and is assimilated by the psyche. All thoughts and actions tend in the direction of the complex; whatever cannot be constrained in this direction is repudiated, or is performed perfunctorily, without emotion and without care. In attending to indifferent matters the most extraordinary compromise formations are produced; slips of the pen referring to the erotic complex creep into business letters, suspicious slips of the tongue occur in speaking. The flow of objective thought is constantly interrupted by invasions from the complex, there are long gaps in one’s thought which are filled out with erotic episodes.

[103] This well-known paradigm shows clearly the effect of a strong complex on a normal psyche. We see how the psychic energy applies itself wholly to the complex at the expense of the other psychic material, which in consequence remains unused. All stimuli that do not suit the complex undergo a partial

apperceptive degeneration with emotional impoverishment. Even the feeling-tone becomes inappropriate: trifles such as ribbons, pressed flowers, snapshots, *billets doux,* a lock of hair, etc., are cherished with the greatest care, while vital questions are often dismissed with a smile or with complete indifference. On the other hand the slightest remark even remotely touching on the complex instantly arouses a violent outburst of anger or pain which may assume pathological proportions. (In a case of dementia praecox one would note: “On being asked whether he was married, the patient broke into inappropriate laughter,” or “the patient began to weep and became completely negativistic,” or “the patient showed blocking,” etc.) If we had no means of feeling our way into the psyche of a normal person in love, his behaviour would seem to us that of an hysteric or a catatonic. In hysteria, where the complex-sensitiveness is far greater than normal, we have almost no means of feeling our way, and must laboriously accustom ourselves to intuiting the meaning of the hysterical affects. This is quite impossible in catatonia, perhaps because we still know too little about hysteria.

[104] The psychological state of being in love could be described as an obsessional complex. Besides this special form of sexual complex, which I have chosen as a paradigm for didactic reasons, since it is the commonest and best-known form of obsessional complex, there are naturally many other kinds of sexual complex which can exert an equally strong influence. Among women the complexes of unrequited or otherwise hopeless love are very common. Here we find an exceedingly strong complex-sensitiveness. The slightest hint from the other sex is assimilated to the complex and elaborated with complete blindness for even the weightiest arguments to the contrary. An insignificant remark of the adored is construed as a powerful subjective proof of his love. The chance interests of the intended become the starting-point for similar interests on the woman’s part—a symptomatic action which rapidly disappears when the wedding finally takes place or if the object of adoration changes. The complex-sensitiveness also shows itself in an unusual sensitiveness to sexual stimuli, which appears particularly in the form of prudery. Those obsessed by the complex ostentatiously avoid in their younger years everything that could remind them of sex—the well-known “innocence” of grown-up daughters. Although they know where everything is and what it means, their whole behaviour gives the impression that they never had an inkling of things sexual. If one has to inquire into these matters for medical reasons, one thinks at first that one is on virgin soil, but one soon finds that all the necessary knowledge is there, except that the patient does not know where she got it from.[12]

Psychoanalysis usually discovers that behind all the resistances there is a complete repertoire of subtle observations and astute deductions. In later years the prudery often becomes unbearable, or the patient displays a naïve symptomatic interest in all sorts of natural situations in which one "may now take an interest because one is past the age …" and so on. The objects of this symptomatic interest are brides, pregnancies, births, scandals, and so on. The fine nose of elderly ladies for these matters is proverbial. They are then passed off as "objective, purely human interest."

[105] Here we have an instance of displacement: the complex must under all circumstances assert itself. Since, for many people, the sexual complex cannot be acted out in a natural way, it makes use of by-ways. During puberty it takes the form of more or less abnormal sexual fantasies, frequently alternating with phases of religious enthusiasm (displacements). In men, sexuality, if not acted out directly, is frequently converted into a feverish professional activity or a passion for dangerous sports, etc., or into some learned hobby, such as a collecting mania. Women take up some kind of philanthropic work, which is usually determined by the special form of the complex. They devote themselves to nursing in hospitals where there are young assistant physicians, or they develop strange eccentricities, a prim, affected behaviour which is meant to express distinction and proud resignation. Artistic natures in particular are wont to benefit by such displacements.[13] There is, however, one very common displacement, and that is the disguising of a complex by the super-imposition of a contrasting mood. We frequently meet this phenomenon in people who have to banish some chronic worry. Among these people we often find the best wits, the finest humorists, whose jokes however are spiced with a grain of bitterness. Others hide their pain under a forced, convulsive cheerfulness, which because of its noisiness and artificiality ("lack of affect") makes everybody uncomfortable. Women betray themselves by a shrill, aggressive gaiety, men by sudden alcoholic and other excesses (also fugues). These displacements and disguises may, as we know, produce real double personalities, such as have always excited the interest of psychological writers (cf. the recurrent problem in Goethe of "two souls," and among the moderns Hermann Bahr, Gorky, and others). "Double personality" is not just a literary phrase, it is a scientific fact of general interest to psychology and psychiatry, especially when it manifests itself in the form of double consciousness or dissociation of the personality. The split-off complexes are always distinguished by peculiarities of mood and character, as I have shown in a case of this kind.[14]

[106] It sometimes happens that the displacement gradually becomes stable and—superficially at least—replaces the original character. Everyone knows people who, judged externally, are enormously gay and entertaining. Inwardly, and sometimes even in private life, they are sullen grumblers nursing an old wound. Often their true nature suddenly bursts through the artificial covering, the assumed blithesomeness vanishes at a stroke, and we are confronted with a different person. A single word, a gesture, if it touches the sore spot, reveals the complex lurking in the depths of the psyche. These imponderabilia of emotional life must be borne in mind before we apply our crude experimental methods to the complicated psyche of the patient. In association tests with patients suffering from a high degree of complex-sensitiveness (as in hysteria and dementia praecox) we find exaggerations of these normal mechanisms; hence their description and discussion will require more than a psychological *aperçu*.

3. THE INFLUENCE OF THE FEELING-TONED COMPLEX ON THE VALENCY OF ASSOCIATIONS

[107] How the complex comes to light in the association experiment has been explained a number of times already, and we must refer the reader to our earlier publications. Here we shall come back to one point only which is of theoretical value. We frequently meet with reactions that are built up in the following manner:

	Stimulus-word	*Reaction*	*Reaction-time (seconds)*
1.	kiss	love	3.0
	burn	burning	1.8
2.	despise	someone	5.2
	tooth	teeth	2.4
3.	friendly	amiable	4.8
	dish	fish	1.6

[108] The first reaction in each of the three examples contains the complex (in 1 and 3 it refers to an erotic relationship, and in 2 to an injury). The second reactions show the perseverating feeling-tone of the preceding reaction, as can be seen from the slightly prolonged reaction time and from their superficiality. As explained in “The Associations of Normal Subjects,” associations like *tooth / teeth* belong to the verbal-motor combinations, *burn / burning* to word-

completion, and *dish / fish* to rhymes. The distraction experiments show definitely that the verbal-motor combinations and clang-reactions increase when attention is distracted. Whenever there is a reduction of attention there is an increase in the superficiality of associations and their valency diminishes accordingly. Therefore, if during an experiment with no artificial distraction there is a sudden striking increase in superficial associations, we are justified in assuming that attention has momentarily been reduced. The cause is to be sought in an *inner distraction*. Following the instructions, the subject has to fix his attention on the experiment, and if his attention diminishes, that is, if for no outward reason it turns away from the meaning of the stimulus-word, then there must be an inner reason for the distraction. We find this mostly in the preceding or even in the same reaction. A strongly feeling-toned idea has come up, a complex which, because of its strong feeling-tone, attains a high degree of clarity in consciousness or, if repressed, exerts an inhibition on the conscious mind, and in this way temporarily checks or reduces the influence of the directing idea (attention to the stimulus-word). The correctness of this supposition can generally be demonstrated, without difficulty, by analysis.[1]

[109] The phenomenon we have described is therefore of practical importance as a complex-indicator. It is of theoretical importance that the complex need not be conscious to the subject. Even when repressed it can exert an inhibition on his consciousness and disturb his attention; in other words, it can check the intellectual performance of consciousness (prolonged reaction-time), or make it impossible (failures to react), or diminish its valency (clang-reactions). The association experiment merely shows details of the effect, whereas clinical and psychological observation shows us the same phenomena on a large scale. A strong complex, for instance a nagging worry, hinders concentration; we are unable to tear ourselves away from it and direct our activity and interest into other channels. Or if we try to do this in order to "forget our worries," we succeed perhaps for a short time but we do it only "half-heartedly"; without our knowing it, the complex prevents us from giving ourselves wholly to the task in hand. We succumb to all kinds of inhibitions; in the pauses of thought ("thought-deprivation") fragments of the complex appear and, as in the association experiment, cause characteristic disturbances in the intellectual performance. We make slips of the pen in accordance with the rules of Meringer and Mayer,[2] we produce condensations, perseverations, anticipations, etc., and Freudian errors which reveal by their content the determining complex. Our slips of the tongue occur at the critical places, that is, when we say words that have a significance for the complex. We make mistakes in reading because we

think we see the complex-words in the text. Frequently these words appear in the peripheral field of vision[3] (Bleuler). In the midst of our "distracting" occupations we catch ourselves singing or whistling a certain melody; the words, which we have great difficulty in remembering, are a complex constellation. Or we keep on murmuring a word, frequently a technical term or a foreign word, which likewise refers to the complex. We may be haunted all day by an obsession, by a melody or a word that is always on the tip of our tongue; these too are complex constellations.[4] Or we make doodles on paper or on the table which are not difficult to interpret in terms of the complex. Wherever the disturbances caused by the complex express themselves in words we find displacements by clang similarities or by combinations of phrases. Here I must refer the reader to the examples given by Freud.[5]

[110] From my own observations I will mention the association of a woman who was pregnant: she reacted to *mild* with *bed*, by which she meant *child / bed*.[6] Then the verbal automatism "Bunau-Varilla"[7] gave by free association the following train of thought: *Varinas-Manila-cigarillo-Havana cigar*. Because I had forgotten my matches I resolved not to extinguish a burning cigar before I had lighted my good Havana with it. The name "Bunau-Varilla" presented itself at just the right moment, when the cigar was on the point of going out. Finally the association *Tagerock / Taganrog*, the latter place-name obsessing a lady whose husband had refused to give her a new morning coat [*Tagerock*].[8]

[111] These examples are meant only to illustrate once again what Freud shows in detail in *The Interpretation of Dreams*, that repressed thoughts disguise themselves in similarities, whether in verbal (clang) similarities or in similarities of visual imagery. The best examples of the latter form of displacement can be seen in dreams.

[112] Those who are afraid of Freud's dream-analysis can find plenty of similar material in melodic automatisms. For instance, someone jokingly remarks in conversation that if one must marry, it should be a proud woman. One of those present, a man who had recently married a woman noted for her pride, began whistling a well-known popular song. As he was a friend of mine, I asked him to tell me the words of the melody. He replied: "What have I been whistling? Oh, nothing. I believe I have often heard it in the street but I don't know the words." I urged him to recall the words, which were well known to me, but it was impossible for him to do so; on the contrary he assured me that he had never heard the words. The refrain was: "My mother told me, do not take a peasant maid."

[113] During an excursion a young lady, walking beside a gentleman whose imminent proposal she hoped for, quietly sang the Wedding March from *Lohengrin*.

[114] A young colleague who had just finished his dissertation was impelled to whistle for half the day Handel's "See, the conquering hero comes."

[115] An acquaintance who was pleased with his new and lucrative position betrayed his feelings by singing the obsessive melody "Are we not born for glory?"

[116] A colleague, meeting a nurse on his rounds, who was supposed to be pregnant, immediately afterwards found himself whistling: "Once there were two royal children, who loved each other so dear."

[117] I do not wish to add unnecessarily to this collection of melodic automatisms; everyone can make the same observations every day. They show us once again how repressed thoughts are disguised. We know that singing and whistling often accompany activities which do not require full "cathexis of attention" (Freud). The residual attention is therefore sufficient to produce a dreamy movement of thoughts relating to the complex. But the purposive activity prevents the complex from becoming clear, it can only show itself indistinctly, as for instance in the melodic automatisms that contain the thought-complex in the usual metaphorical form. The similarity lies in the situation, in the mood ("See, the conquering hero comes," Wedding March, "Once there were two royal children"), or in the words expressed ("Do not take a peasant maid"). In these cases the thought-complex did not come clearly into consciousness but manifested itself more or less symbolically. How far such symbolic constellations can go is best seen from that wonderful example of Freud's in *The Psychopathology of Everyday Life*,[9] where in the verse "Exoriare aliquis nostris ex ossibus ultor" Freud was able to trace his friend's forgetting of the word "aliquis" (*A-liquis-liquid-fluid-miracle of the blood of St. Januarius)* to the overdue menstrual period of his beloved. I shall give a similar example from my own experience as confirmation of the Freudian mechanisms.

[118] A gentleman wished to recite Heine's poem "Ein Fichtenbaum steht einsam" (A pine-tree stands alone). When he came to "Ihn schläfert" (It felt drowsy) he got hopelessly stuck; he had totally forgotten the words "mit weisser Decke" (with white sheet). This lapse of memory in such a well-known poem seemed to me very odd, so I asked him to tell me what came into his mind with the words "with white sheet." The following train of thought resulted: "White

sheet makes one think of the winding-sheet for the dead—a linen cloth with which one covers a dead person—(pause)—now I think of a close friend—his brother recently died quite suddenly—supposed to have died of a stroke—he was very corpulent—my friend is corpulent too, and I have sometimes thought it might happen to him—probably he doesn't take enough exercise—when I heard of his death I suddenly became frightened—it might happen to me, as in our family we are inclined to stoutness—my grandfather also died of a stroke—I am too stout myself and have recently begun a reducing course."

[119] This shows very clearly how the repression can banish similarities from the conscious mind, even when they are concealed as symbols, and "inhibit" them by attaching them to the complex. In consequence, the gentleman at once identified himself unconsciously with the pine-tree enveloped in a white sheet.

[120] We may therefore assume that he wanted to recite the poem as a symptomatic action in order to discharge the excitation caused by the complex. Another favourite sphere for complex constellations is the joke of the pun type. There are people who have a special talent for this, and among them I know some who have very strong complexes to repress. I shall show what I mean by a simple example representative of a whole class.

[121] At a party there was a Mr. X, who made many good and bad puns. While oranges were being handed round he came out with "O-rangierbahnhof" (shunting station). A Mr. Z, who obstinately disputed the complex theory, exclaimed, "I suppose, Doctor, you would conclude from this that Mr. X is thinking of going on a journey." Mr. X said, astonished, "So I am! Recently I have always been thinking of journeys, but I was unable to get away." Mr. X was thinking in particular of a journey to Italy; hence the constellation via the oranges, a package of which he had just received from a friend in Italy. Naturally he was not conscious of the significance of the pun when he made it, as complex constellations always are and must remain obscure.

[122] Dreams, too, are constructed along similar lines; they are symbolic expressions of the repressed complex. In dreams we find excellent examples of expression by similarity of imagery.[10] Freud, as we know, has at last put dream-analysis on the right track. It is to be hoped that psychologists will soon recognize this fact, for the gain would be immense. Freud's dream-interpretation is fundamental in regard to the concept of expression by means of similarity of imagery, which is so very important for the psychology of dementia praecox. In view of this, it may not be superfluous if I add another dream-analysis to those reported in *Studies in Word Association*.[11]

[123] A friend[12] once told me the following dream: *I saw horses being hoisted by thick cables to a great height. One of them, a powerful brown horse which was tied up with straps and was hoisted aloft like a package, struck me particularly. Suddenly the cable broke and the horse crashed to the street. I thought it must be dead. But it immediately leapt up again and galloped away. I noticed that the horse was dragging a heavy log along with it, and I wondered how it could advance so quickly. It was obviously frightened and might easily have caused an accident. Then a rider came up on a little horse and rode along slowly in front of the frightened horse, which moderated its pace somewhat. I still feared that the horse might run over the rider, when a cab came along and drove in front of the rider at the same pace, thus bringing the frightened horse to a still slower gait. I then thought now all is well; the danger is over*.

[124] I took up the individual points of the dream and asked my friend to tell me what came into his mind at each point. The hoisting of the horse: it seemed to him that the horses were being hoisted on to a skyscraper, tied up just like horses that are lowered into the mines to work. X had recently seen in a periodical the picture of a skyscraper being built; the work was done at a dizzy height, and he thought it was heavy work that he would not like. I then tried to analyse the peculiar image of a horse being hoisted on to a skyscraper. X stated that the horse was tied round with straps like the young horses that are lowered into the mines. What particularly struck the dreamer about the picture in the periodical was the *work* at such a dizzy height. The horses in the mines have to work too. Could it be that the expression “mines” (*Bergwerk*, literally ‘mountain-work’) was the result of the condensation of two dream-thoughts: “mountain” as an expression for height, and “work” as an expression for labour, toil, etc.? I therefore asked X for his associations to “mountain,” whereupon he remarked at once that he was a passionate mountain-climber and, just about the time of the dream, had had a great desire to make a high ascent and also to travel. But his wife felt very uneasy about it and would not allow him to go alone. She could not accompany him, as she was pregnant. For this reason they had been obliged to give up the idea of a journey to America (skyscraper), where they had planned to go together. They realized that as soon as there are children in the family it becomes much more difficult to move about and that one cannot go everywhere. (Both were very fond of travelling and had travelled a good deal.) Having to give up the trip to America was particularly disagreeable to him, as he had business dealings with that country and always hoped that by a personal visit he would be able to establish new and important

connections. On this hope he had built vague plans for the future, rather lofty and flattering to his ambition.

[125] Let us briefly summarize what has been said so far. *Mountain* can be interpreted as *height;* to climb a mountain = to get to the top; work = labour. The underlying meaning might be: "By labour one gets to the top." Height is expressed very vividly in the dream by the "dizzy height" of the skyscraper which stands for America, the goal of my friend's ambitions. The image of the horse, which is obviously associated with the idea of labour, seems to be a symbolic expression for "heavy work": the work on the skyscraper upon which the horse was hoisted is very heavy, as heavy as the work the horses have to do in the mines. Moreover, in colloquial speech we have expressions like "to work like a horse," "to be in harness," etc.

[126] The discovery of these associations gives us some insight into the meaning of the first part of the dream; we have found a path obviously leading to the dreamer's intimate hopes and expectations. If we assume that the meaning of this part of the dream is "By labour one gets to the top," the dream-images can be taken as symbolic expressions of this thought.

[127] The first sentences of the dream-narrative read: *I saw horses being hoisted by thick cables to a great height. One of them, a powerful brown horse which was tied up with straps and was hoisted aloft like a package, struck me particularly*. This seems to contradict the analysis so far, that by labour one gets to the top. Of course one can also be hoisted up. Here X recalled that he had always despised tourists who got themselves hoisted up the highest peaks like "sacks of flour." He himself had never needed anybody's help. The various horses in the dream are therefore "other people" who have got to the top but not by their own efforts. The expression "like a package" also seems to express contempt. But where is the dreamer himself represented in the dream? According to Freud he must be represented somewhere; indeed, he is usually the chief actor. This is undoubtedly the "powerful brown horse." The powerful horse resembles him firstly because it can work hard, secondly because the brown colour was described as a "healthy tan" such as mountain-climbers have. So the brown horse may well be the dreamer. It is hoisted up like the others. But the hoisting up of the dreamer himself is not clear; it even contradicts the meaning we have discovered, that by labour one gets to the top.

[128] It therefore seemed to me particularly important to find out whether my conjecture that the brown horse represented the dreamer himself was correct. For this reason I asked him to direct his attention to the passage, *I noticed that*

the horse was dragging a heavy log along with it. He immediately recalled that he used to be nicknamed the “log,” on account of his powerful, stocky figure. So my conjecture was correct: the horse even had his name attached to it. The log impeded the horse, or at least should have done so, and X was surprised that it nevertheless advanced so quickly. To “advance” is synonymous with “getting to the top.” Thus despite the burden or encumbrance X forges ahead, so quickly, indeed, that he has the impression the horse is frightened and could easily cause an accident. On being questioned X stated that the horse, if it fell, could have been crushed by the heavy log, or the force of this moving mass could have “pitched the horse into something.”

[129] This exhausted the associations to this episode. I therefore began the analysis from another point, at the place where the cable broke. I was struck by the expression “street.” X stated that it was the same street in which his business was, where he once hoped to make his fortune. He had hopes of a definite career. Nothing came of it, and even if it had come to anything, his position would have been due less to his own merits than to personal influences. Hence the sentence suddenly becomes clear: *The cable broke and the horse crashed into the street*. It gives symbolical expression to his disappointment. He did not fare like the others who were hoisted to the top without effort. But the others who were preferred to him and got to the top could not start anything useful, for “What could a horse do up there?” They were in a position where they could do nothing. His disappointment over his failure was so great, he said, that for a moment he almost despaired of his future career. In the dream he thought the horse was dead, but soon saw with satisfaction that it got up again and galloped away. So he did not allow himself to be “got down.”

[130] A new section of the dream obviously begins at this point, probably corresponding to a new period of his life, if the interpretation of the preceding part is correct. I therefore asked X to fix his attention on the horse galloping away. He stated that for a moment in the dream he saw another but very indistinct horse appear beside the brown one; it, too, was dragging a log and started galloping off with the roan. But it was very indistinct and disappeared immediately. This fact (together with its late reproduction) indicates that the second horse was under a quite special repressive influence and is therefore very important. X was dragging the log with someone else, and this person must be his wife, with whom he is harnessed “in the yoke of matrimony.” Together they pull the log. In spite of the encumbrance which might easily hinder his progress he was able to gallop, which again expresses the thought that he can’t be got down. X associated the galloping horse with a painting by Welti, *A*

Moonlight Night, where galloping horses are shown on the cornice of a building. One of them is a lusty stallion, rearing up. In the same picture there is a married couple lying in bed. The image of the galloping horse, therefore (which at first galloped in a pair), leads to the very suggestive painting by Welti. Here we get a quite unexpected glimpse into the sexual nuance of the dream, where till now we thought we could see only the complex of ambition and careerism. The symbol of the horse, which so far has shown only the side of the hard-working domestic animal, now takes on a sexual significance, clearly confirmed by the horse scene on the cornice. There the horse is the symbol of passionate impulsive desire, which is obviously identical with the sexual drive. As the associations show, the dreamer feared that the horse would fall or that the impetus of the moving log might "pitch it into something." This *vis a tergo* can easily be interpreted as X's own impetuous temperament, which he feared might involve him in thoughtless acts.

[131] The dream continues: *Then a rider came up on a little horse and rode along slowly in front of the frightened horse, which moderated its pace somewhat.* His sexual impetuosity is bridled. X described the rider as resembling his superior in dress and general appearance. This fits in with the first part of the interpretation: his superior moderates the rash pace of the horse, in other words he hinders the dreamer from advancing too rapidly by keeping ahead of him. But we still have to find out whether the sexual thought we have just discovered is developed further. Perhaps it is hiding behind the expression "a little horse," which seemed to me significant. X stated that the horse was small and dainty like a rocking-horse, and this reminded him of an incident from his youth. While still a boy, he saw a woman far advanced in pregnancy wearing hoops, which were then in fashion. This comical sight seemed to need an explanation, so he asked his mother whether the woman was wearing a little horse under her clothes. (He meant one of those little horses that used to be worn at carnivals or circuses and were buckled to the body.) Since then, whenever he saw women in this condition, it reminded him of his childish hypothesis. His wife, as we have said, was pregnant, and her pregnancy was mentioned as an obstacle to travelling. Here it bridles an impetuosity which we must regard as sexual. This part of the dream is obviously saying: The wife's pregnancy imposes restraints on her husband. Here we have a very clear thought which is evidently strongly repressed and extraordinarily well hidden in the meshes of a dream that seems to be composed entirely of upward-striving symbols. But evidently the pregnancy is still not a sufficient reason for restraint, for the dreamer feared the horse might nevertheless run over the rider. Then comes the slowly advancing

cab which slows down the pace of the horse still more. When I asked X who was in the cab, he recalled that there were children. The children, therefore, were obviously under a repression, with the result that the dreamer only remembered them on being questioned. It was "a whole cartload of children," as the colloquialism used by my friend puts it. The cartload of children checks his impetuosity.

[132] The meaning of the dream is now perfectly clear and runs, in a word, as follows: the wife's pregnancy and the problem of too many children impose restraints on the husband. This dream fulfils a wish, since it represents the restraint as already accomplished. Outwardly the dream, like all others, looks meaningless, but even in its top layer it shows clearly enough the hopes and disappointments of an upward-striving career. Inwardly it hides an extremely personal matter which may well have been accompanied by painful feelings.

[133] In analysing and interpreting the dream fabric, I have refrained from pointing out the numerous analogical connections, the similarities of imagery, the allegorical representation of phrases, etc. No one who carefully examines the material can fail to observe these characteristics of mythological thinking. Here I will only emphasize that the ambiguity of the individual dream-images (Freud's "overdetermination") is one more sign of the vagueness and indefiniteness of dream-thinking. The images in the dream belong to both the complexes (self-assertion and sexuality) of waking life, although in the waking state the two complexes are sharply divided. Owing to the deficient sensitiveness to differences in dreams, the contents of the two complexes can flow into one another, at least in symbolical form.

[134] This phenomenon may not be understandable at first sight, though we can deduce it without difficulty from our earlier premises.[13] Our distraction experiments lend support to the conjecture that in the state of reduced attention thought runs to very superficial associations. The state of reduced attention expresses itself in the decreased clarity of ideas. When ideas are unclear, their differences are unclear too: our sensitiveness to their differences then naturally disappears also, for it is only a function of attention or of clarity (the two are synonymous).

[135] Hence there is nothing to prevent the confusion of different (and otherwise separate) ideas ("psychic molecules"). This fact is expressed experimentally in the increase of indirect associations produced by distraction.[14] As we know, the indirect associations (especially under conditions of distraction) are as a rule nothing but verbal displacements via well-worn combinations of phrase or

sound.[15] Owing to the distraction the psyche becomes uncertain in the choice of expression, and has to put up with all sorts of mistakes in the speech and auditory systems, just like a person suffering from paraphasia.[16] We can easily imagine the outer distraction in our experiment replaced by a complex which exerts its autonomous effect alongside the activity of the ego-complex. We have already discussed the association phenomena that then result. When the complex is hit, conscious association is disturbed and becomes superficial, owing to the flowing off of attention to the underlying complex ("inhibition of attention"). During the normal activity of the ego-complex the other complexes must be inhibited or the conscious function of directed association would be impossible. From this we see that the complex can only make itself felt indirectly by means of indistinct symptomatic associations and symptomatic actions which all have a more or less symbolical character.[17] (See the examples given above.) The effects of the complex must normally be feeble and indistinct because they lack the full cathexis of attention which is taken up by the ego-complex. Hence the ego-complex and the autonomous complex can be directly compared to the two psychic activities in the distraction experiment; and just as in this experiment most of the attention is given to the work of writing the associations down, and only a fraction of it to the act of association itself, so the main part of the attention is directed to the activity of the ego-complex, while the autonomous complex receives only a fraction (provided it is not abnormally excited). For this reason the autonomous complex can only "think" superficially and unclearly, i.e., symbolically, and the end-results (automatisms, constellations) which filter through into the activity of the ego-complex and into consciousness will be similarly constituted.

[136] Here we must interpolate a brief discussion on symbolism. We use the term "symbolical" in contradistinction to "allegorical." Allegory, for us, is the intentional interpretation of a thought, reinforced by images, whereas symbols are only indistinct, subsidiary associations to a thought, which obscure it rather than clarify it. As Pelletier says: "The symbol is a very inferior form of thought. One could define the symbol as the false perception of a relation of identity, or of very great analogy, between two objects which in reality are only vaguely analogous."[18] Thus Pelletier, too, presupposes that for the origin of symbolic associations there must be a lack of sensitivity to differences, or a deficiency in the power of discrimination. We shall now apply these reflections to dreams.

[137] Over the gateway of sleep there stands the imperative: "You wish to sleep, you don't wish to be disturbed by anything."[19] The suggestive force of this acts

as an absolute command for the ego-complex and checks all its associations. But the autonomous complexes are no longer under the direct control of the ego-complex, as we have seen to our satisfaction. They allow themselves to be pushed back only so far, but not to be completely lulled to sleep. They are like little secondary psyches having their own affective roots in the body, by means of which they always remain awake. During sleep they are perhaps just as inhibited as during the waking state, because the imperative command to sleep[20] inhibits all subsidiary thoughts. Yet from time to time they succeed in presenting their blurred, apparently senseless subsidiary associations to the sleeping ego, just as they do during the noise of the day in the waking state. The thought-complexes themselves are unable to appear, as the inhibition due to sleep-suggestion is directed mainly against them. If they can break through the suggestion and obtain full cathexis of attention, of course sleep immediately ceases. We see this happening very frequently in the hypnosis of hysterics: the patients sleep a short time, then they are suddenly frightened awake by a thought-complex. Insomnia is often due to uncontrollable complexes against which the auto-suggestive power of sleep is no longer effective. If by suitable means we reinforce the energy of such patients, they are able to sleep again, because they can then suppress their complexes. But suppressing the complex means nothing more than the withdrawal of attention, i.e., depriving it of clarity. Thus the thought-complexes are dependent on a small fraction of clarity, for which reason they can manifest themselves only in vague, symbolic expressions and also get contaminated for lack of differentiation. We need not assume an actual censorship of dream thoughts in the Freudian sense; the inhibition exerted by sleep-suggestion is a perfectly sufficient explanation.

[138] Finally, we must mention another characteristic effect of complexes: the tendency to contrasting associations. As Bleuler has demonstrated (see ch. 1), all psychic activity that strives towards a goal must be accompanied by contrasts. This is absolutely necessary for proper co-ordination and control. Experience shows that in every decision these contrasts appear as the nearest associations. Normally they do not hinder reflection; on the contrary they promote it and are useful for our actions. But if for any reason the individual’s energy is impaired, he easily becomes the victim of the counterplay of positive and negative, since the feeling-tone of the decision is no longer sufficient to overpower the contrasts and restrain them. We see this particularly often when a strong complex saps the individual’s energy. His energy being diminished, his attention for everything not pertaining to the complex becomes superficial, and the association accordingly lacks definite direction. The result, on the one hand,

is a superficial type of association, and on the other hand contrasts that can no longer be restrained. There are plenty of instances of this in hysteria, where it is purely a matter of emotional contrasts (see Bleuler), and in dementia praecox, where it is a matter of emotional and verbal contrasts (see Pelletier). Stransky found verbal contrasts in his experiments with forced talking.

[139] It now remains only to make a few general remarks on the nature and course of complexes by way of completing chapters 2 and 3.

[140] *Every affective event becomes a complex*. If it does not encounter a related and already existing complex and is only of momentary significance, it gradually sinks with decreasing feeling-tone into the latent mass of memories, where it remains until a related impression reproduces it again. But if it encounters an already existing complex, it reinforces it and helps it to gain the upper hand for a while. The clearest examples of this can be seen in hysteria, where apparent trifles may lead to tremendous outbursts of affect. In such cases the impression has impinged, either directly or symbolically, on the insufficiently repressed complex and thereby evoked a veritable storm, which considering the insignificance of the event often seems altogether disproportionate. We also find that the strongest feelings and impulses are connected with the strongest complexes. It is therefore not surprising that the majority of complexes are of an erotic-sexual nature, as also are most dreams and most of the hysterias. Especially in women, for whom sexuality is the centre of psychic life, there is hardly a complex that is not related to sex. To this fact may well be due the significance of the sexual trauma for hysteria, assumed by Freud to be universal. At any rate, we must always bear sexuality in mind in psychoanalysis, though this does not mean that every hysteria can be traced back exclusively to sexuality. Any strong complex can call forth hysterical symptoms in those so disposed; at least it seems so. I leave all the other types of cemplex unmentioned, as I have attempted to sketch out the commonest kinds elsewhere.[21]

[141] It is in the interests of the normal individual to free himself from any obsessive complex that hinders the proper development of his personality (adaptation to his environment). Time generally takes care of this. Often, however, the individual has to resort to artificial aid in order to rid himself of the complex. We have learnt to regard *displacement* as an important help. People will cling to something new, especially if it contrasts strongly with the complex ("masturbation-mysticism"). An hysteric can be cured if one is able to induce a new complex that will obsess her.[22] Sokolowski says much the same

thing.[23] If the complex is successfully repressed, a marked complex-sensitiveness remains for a long time, i.e., a tendency to recrudescence. If the repression was simply the result of compromise formations, there is a lasting inferiority, an hysteria which allows only limited adaptation to the environment. *But if the complex remains entirely unchanged, which naturally happens only when there is very severe damage to the ego-complex and its functions, then we must speak of dementia praecox*.[24] Note that I am speaking here only from the psychological angle and merely stating what one finds in the psyche of the dementia praecox patient. The view I have expressed in no way precludes the possibility that the insuperable persistence of the complex may be due to an inner poisoning, which may originally have been induced by that very affect. This hypothesis seems to me probable because it is consistent with the fact that in most cases of dementia praecox the complex is in the foreground, while in all *primary* poisonings (alcohol, uremic poisons, etc.) complexes play a minor role. Another fact in favour of my hypothesis is that many cases of dementia praecox begin with striking hysteroid symptoms which only "degenerate" in the course of the disease, becoming characteristically stereotyped or senseless. For this reason the older psychiatrists spoke directly of degenerative hysterical psychoses.

[142] We can therefore formulate the above proposition in the following way. Looking at it from the outside, we see only the objective signs of an affect. These signs gradually (or very rapidly) grow stronger and more distorted, so that on a superficial view it finally becomes impossible to assume a normal psychic content. We then speak of dementia praecox. A more perfect chemistry or anatomy of the future will perhaps demonstrate the objective metabolic anomalies or toxic effects associated therewith. Looking at it from the inside (which naturally can be done only by means of complicated analogical inferences), we observe that the subject can no longer free himself psychologically from the complex—that he associates only to this complex and therefore lets all his actions be constellated by it, the inevitable result being a degeneration of the personality. How far the purely psychological influence of the complex reaches we do not yet know, but we may conjecture that toxic effects also play an important part in the progressive degeneration.

4. DEMENTIA PRAECOX AND HYSTERIA

[143] An exhaustive comparison of dementia praecox and hysteria would be possible only if we had a more thorough knowledge of the disturbances of association in both diseases, and particularly of the affective disturbances in normal persons. This at present is far from being the case. What I intend to do here is simply to review the psychological similarities on the basis of the preceding discussion. As the later account of the association experiment in dementia praecox will show, a preliminary comparison of dementia praecox and hysteria is necessary in order to understand the phenomena of catatonic association.

I. *Disturbances of the Emotions*

[144] The recent investigators of dementia praecox (Kraepelin, Stransky, and others) place the emotional disturbances pretty well in the centre of the clinical picture. They speak on the one hand of *emotional deterioration*, and on the other of the *incongruity of ideational content and affect* (Stransky).

[145] I shall disregard the dulling of the senses found in the terminal stages of the disease, since it can hardly be compared to hysteria (they are of course two totally different diseases), and shall confine myself to the apathetic states during the acute stage. The emotional indifference so striking in many cases of dementia praecox bears a certain resemblance to the "belle indifférence" of many hysterics, who describe their complaints with smiling serenity and thus make an inadequate impression, or speak with equanimity of things that ought to touch them profoundly. In *Studies in Word Association*[1] I have endeavoured to point out how the patients speak quite unemotionally about things which have the most intimate significance for them. This is especially striking in analysis, when one invariably discovers the reason for the inadequate behaviour. So long as the complex which is under special inhibition does not become conscious, the patients can safely talk about it, they can even "talk it away" in a deliberately light manner. This "talking it away" can sometimes amount to "feeling it away," to displacing it by a contrasting mood.

[146] For a long time I had an hysterical patient who, whenever she was plagued by gloomy thoughts, used to work herself up into a mood of boisterous merriment, thus repressing the complex. Whenever she related anything sad that really ought to have moved her deeply, she accompanied it by loud laughter. At other times she spoke with absolute indifference (though its very deliberateness betrayed her) about her complexes, as if they were not of the remotest concern

to her. The psychological reason for this incongruity of ideational content and affect seems to be that the complex is autonomous and allows itself to be reproduced only when *it* wishes. Hence we find that the "belle indifférence" never lasts very long but is suddenly interrupted by a wild outburst of affect, a fit of crying, or something of the kind. We see much the same thing in the euphoric apathy of dementia praecox patients; here too an apparently unannounced moodiness may appear from time to time, or a violent act or startling trick which has nothing in common with their former indifference. Professor Bleuler and I frequently noticed at our joint examinations that as soon as analysis succeeded in laying bare the complex the apathetic or euphoric mask was immediately dropped and was replaced by an adequate affect, often quite a stormy one, just as in hysteria when the sore spot is touched. There are, however, cases where the defensive blocking of the complex can in no way be penetrated. The patients then continue to give "snooty," non-committal answers; they simply refuse to respond to the question asked, and the more direct a bearing the questions have on the complex the less will they answer them.

[147] Occasionally we see that after complex stimuli have intentionally or unintentionally been aroused in apparently apathetic patients, a reaction having a distinct relation to the stimulus appears. The stimulus therefore acted after a certain period of incubation. I have often found with hysterics that in conversation they spoke with apparently affected indifference and superficiality about certain critical points, so that I had to wonder at their pseudo self-control. A few hours later I would be called to the ward because this very patient was having an attack, and it was then discovered that the conversation had subsequently produced an affect. The same thing can be observed in the origin of paranoiac delusions (Bleuler). Janet[2] observed that his patients remained calm at the moment of an event that ought really to have excited them. Only after a latency period of several hours or even days did the corresponding affect appear. I can confirm this observation of Janet's. Baetz, on the occasion of an earthquake, was able to observe in himself the phenomenon of what he calls "emotional paralysis."[3]

[148] *The affective states without adequate ideational content*, which are so common in dementia praecox, likewise have their analogies in hysteria. We need only remember, for instance, the anxiety states in obsessional neurosis. The ideational content is as a rule so inadequate that the patients themselves clearly recognize its logical untenability and regard it as senseless, yet it *seems* to be the source of anxiety. That this is not so has been shown by Freud in a way that so far has not been refuted, and that I can only corroborate. I recall the

patient in *Studies in Word Association*[4] who suffered from the obsession that she had infected the clergyman and doctor with her obsessional ideas. In spite of proving to herself over and over again that this idea was quite unfounded and senseless, she was nevertheless tormented by the greatest anxiety. The frequent depressions in hysteria are in the great majority of cases traced back by the patients to what can only be classified as "screen causes." In reality we are dealing with normal reflections and thoughts hidden in the repression. A young hysteric suffered from such a deep depression that at every answer she burst into tears, for no apparent reason. She obstinately traced it back to pains in the arm which she occasionally felt while working. Finally it turned out that she was having a love-affair with a man who did not want to marry her, and this caused her constant worry. So before we say that the patient is depressed for some "inadequate" reason, we must bear in mind the mechanisms existing in every normal person, which always strive to repress anything unpleasant and bury it as deeply as possible.

[149] The *explosive excitements* in dementia praecox may be brought about in the same way as the explosive affects in hysteria. Everyone who has treated hysterical patients knows the sudden outbursts of affect and acute exacerbations of the symptoms. In many cases we are up against a psychological riddle and content ourselves with noting: "The patient is again excited." But careful analysis will always discover a clear cause: a thoughtless remark, a disturbing letter, the anniversary of some crucial event, etc. Only a trifle is needed, sometimes merely a symbol; this is sufficient to release the complex.[5] So also in dementia praecox one may, by careful analysis, sometimes find the psychological clue that leads to the cause of the excitement. Naturally we cannot do this in all cases because the disease is much too obscure; but we have absolutely no reason to suppose that no sufficient connection exists.

[150] That the affects in dementia praecox are probably not extinguished but are merely displaced and blocked in some peculiar way can be seen on those rare occasions when we are granted complete catamnesic insight into the disease.[6] Outwardly senseless affects and moods can be explained subjectively as hallucinations and pathological ideas which, because they belong to the complex, can be reproduced only with difficulty or not at all when the disease is at its height. If a catatonic is constantly preoccupied with the hallucinatory scenes that crowd into his consciousness with elemental force and a much stronger feelingtone than external reality, we can readily understand why he is incapable of reacting adequately to the doctor's questions. Or if the patient, like

Schreber, for instance, perceives all the people around him as “fleeting-improvised men,”[7] it is obvious that he cannot react adequately to the stimuli of reality, although he reacts adequately in his own way.

[151] A typical feature of dementia praecox is *lack of self-control* or the *unruliness of affects*. We find this wherever emotivity is pathologically intensified, above all in hysteria and epilepsy. The symptom merely shows that the ego-synthesis is seriously disturbed, i.e., that there are very powerful autonomous complexes which no longer fit into the hierarchy of the ego-complex.

[152] The characteristic lack of *emotional rapport* in dementia praecox is sometimes found in hysteria, when we are unable to capture the interest of the patient and penetrate the complex. In hysteria this condition is only temporary, because the intensity of the complex varies. In dementia praecox, where the complex is very stable, we can get emotional rapport only for short moments when we penetrate the complex. In hysteria we gain something by this penetration, but in dementia praecox we gain nothing, for immediately afterwards the personality confronts us just as coldly and strangely as before. Under certain conditions analysis may even cause a flaring up of the symptoms, but in hysteria there is usually some improvement afterwards. Anyone who has penetrated the mind of an hysteric by analysis knows that he has gained moral power over the patient. (Incidentally, this is also true of ordinary confessions.) In dementia praecox, on the other hand, everything remains as before even after very thorough analysis. The patients cannot feel their way into the mind of the doctor, they stick to their delusional assertions, they attribute hostile motives to the analyst, they are and remain, in a word, uninfluenceable.

II. *Abnormalities of Character*

[153] Character disturbances claim an important place in the symptomatology of dementia praecox, although we cannot really speak of a “dementia-praecox character.” One could just as well speak of an “hysterical character,” smuggling into it all kinds of prejudices, such as moral inferiorities and the like. Hysteria does not create any special character, it merely exaggerates the already existing traits. Thus all temperaments can be found among hysterics: there are egoistic and altruistic personalities, criminals and saints, sexually excited and sexually frigid natures, and so on. The only thing characteristic of hysteria is the existence of a powerful complex incompatible with the ego-complex.

[154] Among the characterological disturbances in dementia praecox we might mention *affectation* (mannerisms, eccentricity, mania for originality, etc.). We frequently meet this symptom in hysteria, especially when the patients find themselves out of their social element. A very common form of this affectation is the pretentious and artificial behaviour of women of a lower social position—dressmakers, nurses, maids, etc.—who mix with those socially above them, and also of men who are dissatisfied with their social status and try to give themselves at least the appearance of a better education or of à more imposing position. These complexes are frequently associated with aristocratic airs, literary and philosophic enthusiasms, extravagant, "original" views and utterances. They show themselves in exaggerated mannerisms, especially in a choice of language that abounds in bombastic expressions, technical terms, affected turns of speech and high-sounding phrases. We find these peculiarities chiefly in those cases of dementia praecox who have the "delirium of social elevation" (Krafft-Ebing) in some form or other.

[155] The affectation, in itself, contains nothing specific of dementia praecox; the disease takes over the mechanism from the normal, or rather from the caricature of the normal, hysteria. Such patients have a special predilection for *neologisms*, which they use mostly as learned or otherwise distinguished-sounding technical terms. One of my women patients called them "power-words" and showed a special liking for the most abstruse expressions, which obviously seemed to her fraught with meaning. The "power-words" serve among other things to emphasize the personality and to make it as imposing as possible. The emphasis laid on "power-words" accentuates the value of the personality in the face of doubt and hostility, and for this reason they are frequently used as defensive and exorcistic formulae. A dementia-praecox patient under my care, if the doctors refused him anything, used to threaten them with the words: "I, the Grand Duke Mephisto, shall have you treated with blood vengeance for orang-outang representation." Others, like Schreber, use the power-words to exorcise their voices.[8]

[156] The affectation also expresses itself in gesture and handwriting, the latter being adorned with all kinds of peculiar flourishes. Normal analogies can be found in young girls who, out of caprice, affect an especially striking or original script. Dementia-praecox patients frequently have a characteristic handwriting: it expresses the contradictory tendencies in their psyche, the script being now sloping and cursive, now upright, now large, now small. The same thing can be seen in temperamental hysterics, and it is often easy to show that the change in

writing begins at the place where the complex is touched. Even with normal people one can often see disturbances at such places.

[157] Affectation is naturally not the only source of neologisms. A large number of them come from dreams, and especially from hallucinations. They are, not uncommonly, verbal condensations and clang associations that can be analysed, and whose origin can be explained according to the principles outlined in the preceding chapters. (There are excellent examples of this in Schreber.) The origin of the "word salad" can be also understood in terms of Janet's *abaissement du niveau mental*. Many schizophrenics who are inclined to be negativistic and will not react to the questions show "etymological" leanings: instead of answering, they dissect the question and embellish it with clang associations, which amounts to a displacement and concealment of the complex. They do not want to answer the question and therefore divert attention to its phonetic aspects. (This is analogous to not answering the stimulus-word.[9]) There are many other indications that the clang elements of language impress dementia-praecox patients more than others; they are very fond of dissecting and interpreting words.[10] In general the unconscious shows a similar liking for new word formations. (Cf. the "heavenly languages" of the classic somnambulists, especially the interesting productions of Hélène Smith.[11])

[158] *Lack of consideration, narrow-mindedness, and inaccessibility to persuasion* are found in normal and pathological subjects, particularly where affective causes are involved. It needs, for instance, only a firm religious or some other conviction to make a man under certain circumstances narrow-minded, ruthless, and cruel. For this there is no need to assume an emotional deterioration. Owing to their excessive sensitiveness, hysterics become selfish, inconsiderate, a torment to themselves and others. Here again there need be no deterioration; they are merely blinded by affect. Nevertheless I must once again repeat the oft-mentioned proviso that between hysteria and dementia praecox there is only a *similarity* of psychological mechanism and not an *identity*. In dementia praecox these mechanisms go much deeper, perhaps because they are complicated by toxic effects.

[159] The *stupid behaviour* of hebephrenics has analogies with the moria states[12] of hysterics. For a long time I had under my observation an hysterical woman of high intelligence who frequently suffered from states of excitement during which she showed a peculiarly childish and silly behaviour. This regularly happened when she had to repress sad thoughts associated with her complex. Janet, too, was acquainted with this behaviour, which naturally is found in all

gradations: “These persons play a sort of comedy, they pretend to be young, naïve, coaxing, they feign complete ignorance and finally get to be like little children.”[13]

III. *Intellectual Disturbances*

[160] Consciousness in dementia praecox shows anomalies which have often been compared with those of hysteria or hypnosis. In many cases there are signs of a narrowing of consciousness, i.e., restriction of clarity to one idea, with abnormal increase in the indistinctness of all subsidiary associations. This, in the opinion of several authors, would explain the blind acceptance of an idea without inhibition or correction, a phenomenon analogous to suggestion. Others seek to explain the peculiar suggestibility of catatonics (echo symptoms) on this basis, too. To this one can only object that there is a considerable difference between normal and catatonic suggestibility. In normal suggestibility we note that the subject will keep as close as possible to the suggestion if he attempts to realize it. In hysteria, according to the degree and nature of the illness, there are all sorts of peculiar embellishments; for instance, the suggestion to sleep may easily change into hystero-hypnosis or into an hysterical twilight state, or the suggestions are only partially executed, with the addition of subsidiary actions that were not intended.[14] For this reason hypnosis is often more difficult to control in severe hysterics than in normal persons. In catatonia the chance factor in the phenomena of suggestion is still greater. Often suggestibility is limited entirely to the motor sphere, resulting only in echopraxia and often only in echolalia. Verbal suggestion can seldom be carried out in dementia praecox and even if successful the effects are uncontrollable and seemingly fortuitous. There are always a number of extraneous elements mixed in with the normal suggestibility. Nevertheless, there is no reason why catatonic suggestibility, at least in its normal vestiges, should not be reduced to the same mechanisms as in hysteria. We know that in hysteria the uncontrollable element in the suggested effect is to be sought in the autonomous complex. There is no reason to assume that this is not the case also in dementia praecox. Similarly capricious behaviour is found in dementia praecox with regard to other therapeutic measures, such as transfer to another institution, discharge,[15] education by example, and so forth. How very much the improvement in old catatonics when transferred to other surroundings depends on psychological factors has been shown by Riklin in his extremely valuable analyses.[16]

[161] *Lucidity of consciousness* in dementia praecox is subject to every form of clouding; it may change from perfect clarity to deepest confusion. Since Janet the fluctuations of lucidity in hysteria have become almost proverbial. Here we are able to distinguish two kinds of disturbance: momentary and persistent. The momentary disturbance may be a mild "engourdissement" of a few seconds' duration, or an hallucinatory, ecstatic irruption, also of very short duration. In dementia praecox we are familiar with the abrupt blockings, momentary "thought-deprivation," and the lightning-like, hallucinatory irruption of bizarre impulses. The persistent disturbances of *consciousness* in hysteria appear in the form of somnambulous states with numerous hallucinations, or in the "lethargic" (Löwenfeld) or cataleptic states. In dementia praecox they are seen in the persistent hallucinatory phases with more or less marked confusion, and in stuporous states.

[162] *Attention* is almost regularly disturbed, but these disturbances also play a large role in hysteria. Janet says of "les troubles de l'attention": "One can say that the principal disturbance consists not in a suppression of the intellectual faculties but in the difficulty of fixing the attention. Their [the patients'] minds are always distracted by some vague preoccupation, and they never give themselves entirely to the object which one assigns to them." As shown in the first chapter, Janet's words can also be applied to dementia praecox. What disturbs the patients' concentration is the autonomous complex, which paralyses all other psychic activities. Curiously enough, this fact escaped Janet. The striking thing in hysteria, as in all affective states, is that the patients always come back to their "story" (as in traumatic hysteria) and that all their thoughts and actions are constellated only by the complex. A similar limitation, greatly intensified, can often be observed in dementia praecox, especially in its paranoid forms. It is hardly necessary to give examples.

[163] *Orientation* varies in the same capricious way in both diseases. In dementia praecox, when *we* are not actually dealing with marked excitement accompanied by deep confusion, we often get the impression that the patients are disturbed merely by illusions but that at bottom they are correctly oriented. We do not always have this impression in hysteria, though we can see for ourselves that correct orientation does exist by hypnotizing the patient. Hypnosis represses the hysterical complex and leads to reproduction of the ego-complex. As in hysteria the disorientation is due to a pathogenic complex momentarily pushing aside the ego-complex, so in dementia praecox it may easily happen that quite clear answers are followed the next moment by the most extraordinary utterances.[17] Lucidity of consciousness is especially often

impaired in the acute stage of the disease, when the patients are in a real dream, i.e., in a “complex-delirium.”[18]

[164] The *hallucinatory delirious phases* can, as we have said, be paralleled by those in hysteria, though it should always be borne in mind that we are dealing with two different diseases. The content of hysterical delirium, as can easily be seen if we employ Freud’s method of analysis, is always a clear complex-delirium; that is to say the pathogenic complex appears autonomously and works itself out in some way, usually in the form of a wish-fulfilment.[19]

[165] We do not have to look far in order to find something similar in the acute phases of dementia praecox. Every psychiatrist is familiar with the deliria of unmarried women, who act out betrothals, marriages, coitus, pregnancies, and births. I mention this only in passing and shall come back to these questions later, as they are of great importance in determining the symptoms.[20]

[166] This brings us to the *delusions and hallucinations*. Both symptoms occur in all mental diseases and also in hysteria. We must therefore be dealing with mechanisms which in general are preformed and are set in motion by various toxic agents. What chiefly interests us here is the content of the delusions and hallucinations, amongst which we include pathological ideas. Once more hysteria, the most transparent of the mental diseases, can help us a little. The delusions may be paralleled, in a sense, by the obsessional ideas, and also by the narrow-minded prejudices based on affect, which are so often met with in hysteria, and finally by the stubbornly asserted bodily pains and ailments. I cannot recapitulate the genesis of delusional assertions and must presuppose a knowledge of Freud’s writings. The delusional assertions of the hysteric are displacements; that is to say, the accompanying affect does not really belong to them but to a repressed complex which is disguised by this manoeuvre. An insuperable obsession merely shows that some complex (usually a sexual one) is repressed, and the same is true of all the other obstinately asserted hysterical symptoms. We now have good grounds for supposing—I base this on dozens of analyses—that a fundamentally similar process is at work in the delusions of dementia praecox.[21]

[167] I will illustrate this by a simple example.[21a] A 32-year-old servant had her teeth extracted in order to have a complete new set. During the night following the operation she got into a violent state of anxiety. She considered herself damned and lost forever because she had committed a great sin: she should never have allowed her teeth to be extracted. People must pray for her that God

might forgive her this sin. The next day she was quiet and continued her work, but in the following nights the anxiety states grew worse. I examined the patient for her antecedents, and also her employers, in whose service she had been for a number of years. Nothing, however, was known, or rather the patient denied any kind of emotivity in her former life, emphasizing with great affect that the extraction of her teeth was the sole cause of her illness. The illness rapidly grew worse, and she had to be interned, with all the symptoms of catatonic excitement. It was then discovered that for many years she had been concealing an illegitimate child, of whose existence even her family had not the slightest knowledge. For a year past she had been acquainted with a man she wanted to marry, but she could never fully make up her mind because she was continually tormented by the fear that her lover would reject her if he knew of her former life. Here, then, was the source of her anxiety, and at the same time it shows why the affect connected with the extraction of teeth was bound to be inappropriate.

[168] The mechanism of displacement paves the way for an understanding of the origin of delusional assertions. The way is strewn with obstacles because the notorious strangeness of the delusions in dementia praecox hardly permits of any analogies. Nevertheless, normal and hysterical psychology both give us a number of clues that allow us to get a little nearer at least to the commonest forms of delusion.

[169] *Delusions of reference* have been thoroughly analysed and explained by Bleuler.[22] Feelings of reference are found wherever there is a strongly accentuated complex. It is a peculiarity of all strong complexes to assimilate everything they possibly can; thus, it is a well-known fact that when we are in the grip of a powerful affect we often have the feeling that “people will notice.” An acute affect will cause quite unimportant happenings to be assimilated from the environment, thus producing the grossest falsifications of judgment. When we meet with some mishap we at once jump to the conclusion, during the first moment of anger, that someone has injured or insulted us *deliberately*. In hysteria, depending on the magnitude and duration of the affect, prejudices of this kind can establish themselves for a long time, easily producing mild delusions of reference. From this it is but a step to the delusional assumption of strange “machinations.” This road leads straight to paranoia.[23] It is often difficult, however, to reduce the incredible and grotesque delusions of dementia praecox to delusions of reference. When, for example, a dementia-praecox patient feels that everything happening inside him and outside him is unnatural and “faked,” it is probable that we are dealing with a more elemental

disturbance than a delusion of reference.[24] Obviously there is something in his apperception that prevents normal assimilation. There is either a shade too little or a shade too much, and this gives his apperception a peculiar accent.

[170] There are analogies to this in hysteria: disturbances in the *feelings of activity*. Every psychic activity is accompanied, apart from the pleasure/pain feeling-tone, by still another feelingtone which qualifies it in a special way (Höffding). What is meant by this can best be explained by Janet's important observations on psychasthenics. Here voluntary decisions and actions are not accompanied by the feelings that ought normally to accompany them but by "sentiments d'incomplétude," for instance. "The subject feels that the action is not completely finished, that something is lacking." Or else every voluntary decision brings with it a "sentiment d'incapacité": "These persons experience in advance painful feelings in the very thought that it is necessary for them to act; they fear action above all things. Their dream, as they all say, is of a life where there will be nothing more to do."[25] One abnormality in the feeling of activity which is extremely important for the psychology of dementia praecox is the "sentiment d'automatisme."[26] About this one patient says: "I am unable to give an account of what I really do, everything is mechanical in me and is done unconsciously. I am nothing but a machine."[27] Closely related to this is the "sentiment de domination."[28] A patient describes this feeling as follows: "For four months I have had queer ideas. It seems to me that I am forced to think them and say them; someone forces me to speak and suggests coarse words, it is not my fault if my mouth acts in spite of me."

[171] A dementia-praecox patient might talk like this. The question whether it might not be a case of dementia praecox is therefore permissible. When reading Janet's work I took careful note whether there might not be cases of dementia praecox among his clinical material, as might easily happen with a French author. But I found nothing suspicious and have no reason to assume that the patient was suffering from dementia praecox. Moreover we frequently hear such remarks from hysterical patients, especially from somnambulists, and we find something similar in normal people who are dominated by an unusually strong complex, for instance in poets and artists. (Cf. what Nietzsche says about the origin of *Zarathustra*.[29]) A good example of disturbance in the feelings of activity is the "sentiment de perception incomplète."[30] A patient says: "It is as though I saw things through a veil, a mist, or through a wall which separates me from reality." A normal person who is under the direct influence of a powerful affect might express himself in a similar manner. Schizophrenics also talk like

this when they speak of their uncertain perception of their surroundings ("It seems to me as though you were the doctor," "They say it is my mother," "It looks like Burghölzli but it is not").[31] When a patient of Janet's says: "The world seems to me like a gigantic hallucination," this is in the fullest sense true of schizophrenics, who continually live in a dream (especially in the acute phases) and act accordingly both during the disease and in the catamnesis.

[172] The "sentiments d'incomplétude" apply particularly to affects. A patient of Janet's says: "It seems to me that I shall not see my children again; everything leaves me indifferent and cold, I wish I could despair, cry out with pain. I know that I ought to be unhappy but I cannot be so, I have neither pleasure nor pain. I know that a meal is good but I swallow it because it is necessary, without finding in it the pleasure I would have found before. … There is an enormous thickness that prevents me from feeling any moral impressions." Another patient said: "I would like to try to think of my little girl but I cannot, the thought of my child barely passes through my mind, it passes and leaves me without any feeling."

[173] I have repeatedly heard spontaneous statements of this kind from hysterical patients as well as from schizophrenics who were still able to give information. A young woman who fell ill with catatonia and had to part from her husband and child in particularly tragic circumstances displayed a *total* lack of affect for all reminiscences of her family. I put the whole sad situation before her and tried to evoke an adequate feeling. While I was describing it she laughed, and when I had finished she became calm for a moment and said, "I simply can't feel any more."

[174] In our view the "sentiments d'incomplétude" are products of inhibition deriving from an overwhelmingly powerful complex. When we are dominated by a complex only the ideas associated with it have full feeling-tone, i.e., full clarity; all other perceptions within or without are subject to the inhibition, so that they become unclear and lose their feeling-tone. That is the underlying cause of the incompleteness of the activity feelings and also of the lack of affect. These disturbances account for the feeling of strangeness. In hysteria the reasoning faculty is preserved and this prevents the feeling from immediately being projected outside as in dementia praecox. But if we assist the projection by allowing certain superstitious ideas to come into play, we immediately get an explanation in terms of some power coming from outside. The clearest examples of this are spiritualistic mediums, who trace back a mass of trivialities to transcendental causes—though, we must admit, they never do it as clumsily

and grotesquely as schizophrenics. Only in normal dreams do we observe anything similar, where the projection takes place in an absolutely natural and naive way. The psychological mechanisms of dreams and hysteria are closely related to those of dementia praecox. A comparison with dreams, therefore, is not too daring. In dreams we see how reality is spun round with fantasy creations, how the pale memories of the waking state assume tangible form, and how the impressions of the environment are transmogrified to suit the dream. The dreamer finds himself in a new and different world which he has projected out of himself. Let the dreamer walk about and act like a person awake, and we have the clinical picture of dementia praecox.

[175] I cannot discuss all the forms of delusion here, but should like to say a few words about the well-known delusion that the patient's thoughts are being influenced. The influencing of thought can take many forms, the commonest being "thought deprivation." Schizophrenics often complain that their thoughts are taken away from them[32] when they wish to think or say something.[33] By means of projection they frequently make some unknown power or agency responsible. Outwardly, thought-deprivation shows itself in the form of blockings: the investigator suddenly gets no more answers to his questions.[34] The patient may then say that he cannot answer because his thoughts have been "taken away" from him. The association experiment has taught us that prolonged reaction-times and failures to react ("faults") generally occur when a complex has been touched: the strong feeling-tone inhibits association. This phenomenon is found in more intensified form in hysteria, when at critical points the patient "simply cannot think of anything." This is already "thought deprivation." The mechanism in dementia praecox is the same; here too the thought is inhibited at points where the complex is touched (in the experiment or in conversation). One can easily observe this when, in suitable cases, one talks first about matters indifferent to the patient and then about the complex. With the indifferent material the answers follow smoothly, while with the complex one blocking succeeds another; the patients either answer nothing at all or else give the most evasive answers it is possible to imagine. Thus, with female patients who are unhappily married, it is impossible to obtain any precise statements about their husbands, whereas about anything else they volunteer the most detailed information.

[176] Another phenomenon to be considered is compulsive thinking. Weird or absolutely senseless thoughts force themselves on the patient, which he is compelled to ponder and to go on thinking. We have an analogy to this in psychogenic obsessional thinking: as a rule the patients fully realize the

absurdity of the thoughts but are quite unable to repress them.[35] The influencing of thought also appears in the form of “inspirations.” That this is a phenomenon not restricted to dementia praecox is shown by the very word “inspiration”: it designates a psychic event that takes place wherever there is an autonomous complex. It is a sudden irruption of the complex into consciousness. “Inspirations” are not at all unusual in religious people; modern Protestant theologians have even devised the name “inner experience” for them. Inspiration is an everyday occurrence in somnambulism.

[177] Finally, there is a special form of blocking which one of my women patients called *“Bannung”*— “captivation” or “fascination.”[36] Sommer terms it “visual fixation.” We also find “interdiction” in association experiments even outside dementia praecox, especially in states of emotional stupidity. This state may sometimes be induced by the experiment itself or by a complex stimulated during the experiment. The patients then cease to react (at least for a time) to the stimulus word; they simply name objects in the environment. I have noticed this especially in imbeciles, but also in normal people under the influence of a strong affect, in hysterics when the complex is touched, as well as in dementia praecox.

[178] “Fascination” is a drawing away of attention from the stimulus-word to the environment for the purpose of covering up the vacuum of associations, or the complex producing it. It is the same in principle as breaking off an unpleasant conversation by suddenly starting to speak of something quite commonplace and beside the point. Any object in the environment will serve as a point of departure. We have, therefore, sufficient justification for putting “fascination” on a level with normal mechanisms.

[179] All these disturbances appear in dementia praecox grouped round the complex and belong to the defence mechanisms. At this point we must also discuss *negativism*. The prototype of negativism is *blocking*, which in certain cases may easily give the impression of a deliberate refusal, just like the “I don’t know” of hysterics. Hence one can just as well speak of “negativism” when the patients refuse to answer questions. Passive negativism readily passes over into active negativism: the patients then show psychic resistance to exploration. If we disregard the cases where negativism has intensified into a general mood of defence, we find, in patients who are still accessible, negativism as well as blocking where the complex is located. As soon as the association experiment or the exploration probes the complex, the sore spot, the patient refuses to answer and draws back, just as the hysteric employs all sorts

of subterfuges to conceal the complex. What is particularly striking in negativism is the strong tendency of catatonic symptoms to become generalized. Whereas in hysteria, despite a very evident and aggravating negativism, certain lines of approach to the emotions still remain open, the negativistic catatonic shuts himself up completely, so that for the moment at least there is no means of penetration. Occasionally a single critical question can induce negativism. A special form of negativism is the "irrelevant answer," which we know in similar form in the Ganser syndrome. In both cases there is a more or less unconscious refusal to respond to the question, hence something very like what we find in "fascination" and in "thought deprivation." There are good reasons for this in the Ganser syndrome, as the studies of Riklin and myself may have made clear: the patients want to repress their complex. It is probably the same in dementia praecox. In the psychoanalysis of hysteria we regularly find irrelevant answers or "talking round" the complex, and we find the same thing in dementia praecox, only here the symptom (and all other catatonic symptoms) shows a strong tendency to generalization. The catatonic symptoms in the motor sphere can easily be thought of as the spreading effects of this generalization. This probably applies to the majority of cases. It is true that catatonic symptoms also occur in focal and general disturbances of the brain, where we cannot very well imagine a psychological nexus. But here again we find, at least as frequently, hysterical symptoms whose psychic causation is an established fact. What we should learn from this is never to forget the possibility of contrary explanations.

[180] *Hallucination* is simply the outward projection of psychic elements. Clinically we know all gradations, from inspirations and pathological ideas to loud auditory hallucinations and vivid visions. Hallucinations are ubiquitous. Dementia praecox merely sets in motion a preformed mechanism which normally functions in dreams. The hallucinations of hysteria, like those of dreams, contain symbolically distorted fragments of the complex. This is also true of the majority of hallucinations in dementia praecox,[37] though here the symbolism is carried much further and is more dreamlike in its distortion. Distortions of speech, along the lines of dream paraphasias (cf. Freud, Stransky, Kraepelin), are extraordinarily common; mostly they are contaminations. A patient who was presented in the clinic, noticing a Japanese in the front row of students, heard his voices call out to him "Japan-sinner" [*Japansünder*]. It is remarkable that not a few patients who delight in neologisms and bizarre delusional ideas, and who are therefore under the complete domination of the complex, are often corrected by their voices. One of my patients, for example, was twitted by the voices about her delusions of grandeur, or the voices

commanded her to tell the doctor who was examining her delusions “not to bother himself with these things.” Another patient, who has been in the clinic for a number of years and always spoke in a disdainful way about his family, was told by the voices that he was “homesick.” From these and numerous other examples I have gained the impression that the correcting voices may perhaps be irruptions of the repressed normal remnant of the ego-complex. That the normal ego-complex does not perish entirely, but is simply pushed aside by the pathological complex, seems borne out by the fact that schizophrenics often suddenly begin to react in a fairly normal manner during severe physical illnesses or any other far-reaching changes.[38]

[181] *Disturbances of sleep* are quite usual in dementia praecox and manifest themselves in a variety of ways. Dreams are often extraordinarily vivid, so that we can well understand why the patients are incapable of correcting them. Many patients derive their delusional ideas almost exclusively from their dreams, to which they attribute real validity.[39] The role that vivid dreams play in hysteria is well known. Apart from dreams, sleep can be disturbed by various other irruptions of complexes, such as hallucinations, autochthonous ideas, etc., just as hypnosis may be in certain hysterics. Schizophrenics often complain about an unnatural sleep, which is not real sleep at all but merely an artificial rigidity. We hear similar complaints wherever there is a strong complex that cannot be entirely extinguished by the sleep inhibition and accompanies sleep as a constant undertone (e.g., melancholia, depressive affects in hysteria). Not infrequently, intelligent hysterics feel the “restlessness of the complex” in their sleep and can describe it precisely. Thus, a patient of Janet’s said: “There are always two or three of my personalities who do not sleep, although during sleep I have fewer personalities; there are some who sleep but little. These personalities have dreams, but the dreams are not the same: I feel that there are some who dream of different things.” This, in my view, aptly expresses the feeling of the unremitting activity of autonomous complexes, which will not submit to the sleep inhibition exercised by the ego-complex.

IV. *Stereotypy*

[182] By stereotypy in its widest sense we mean the persistent and constant reproduction of a certain activity (verbigeration, catalepsy, stock phrases, perseveration, etc.). These phenomena are among the most characteristic symptoms of dementia praecox. At the same time, stereotypy in the form of automatization is one of the commonest phenomena in the development of the normal psyche (Spencer). All our faculties and the whole progress of our personality depend on automatizations. The process that leads to this result is as follows: In order to perform a certain activity we direct all our attention to the ideas relating to it, and through this strong feeling-tone we engrave the various phases of the process on our memory. The result of frequent repetition is that an ever smoother "path" is formed, along which the activity comes to move almost without our help, i.e., "automatically." Only a slight impulse is needed to set the mechanism going. The same thing may also take place passively when there is a strong affect. We can be compelled by an affect to perform certain actions, with great inhibitions at first, but later, with constant repetition of the affect, the inhibitions become less and less, and finally the reaction follows promptly even on a very slight impulse. This can be observed particularly well in the bad habits of children.

[183] The strong feeling-tone, then, creates a path, which amounts to saying what we have already said about complexes. Every complex has a tendency to autonomy—to act itself out independently; it has a greater tendency to persistence and reproduction than ordinary, indifferent thought and so has a better chance of becoming automatic. Hence, when something becomes automatic in the psyche an antecedent feeling-tone must be postulated.[40] The clearest example of this is hysteria, where all the stereotypies, such as attacks of cramp, trance-states, complaints, and symptoms, can be traced. As we have already remarked, the collective term "feeling-tone" includes "attention-tone." plaints, and symptoms, can be traced back to the underlying affects. In the normal association experiment we usually find perseveration where the complex is located.[41]

[184] If there is a very strong complex, all progress adapted to the environment ceases and the associations revolve entirely round the complex. By and large this is what happens in hysteria, where we find very strong complexes. The progress of the personality is retarded, and a large part of the psychic activity is

expended in varying the complex in all possible ways (symptomatic actions). Not for nothing does Janet call attention to the general disturbances in "obsessed" persons, of which I mention the following: indolence, irresolution, retardation, fatigue, lack of achievement, aboulia, inhibition.[42] If a complex succeeds in becoming fixed, monotony results, especially monotony of the outward symptoms. Who does not know the stereotyped, exhausting complaints of hysterics and the stubborn, invincible nature of their symptoms? Just as a constant pain will always call forth the same monotonous cries of distress, so a fixed complaint will gradually stereotype the individual's whole mode of expression, so that in the end we know that day after day we shall receive with mathematical accuracy the same answer to the same question.

[185] In these automatic processes are to be found the normal prototypes of stereotypy in dementia praecox. If we examine the beginnings of linguistic or mimic stereotypies we can often find the emotional content that belongs to them.[43] Later the content grows more and more indistinct, just as in normal and hysterical automatisms. Only, the corresponding process in dementia praecox seems to run a more rapid and thorough course, so that it soon loses all content and affectivity.

[186] Experience shows, without any doubt, that in dementia praecox not only the content of the complex becomes stereotyped but also material that is obviously quite fortuitous. Thus, verbigerating patients will seize on a stray word and repeat it constantly. Heilbronner, Stransky, and others may be right in interpreting such phenomena as symptoms of the associative "vacuum." The motility stereotypies can be interpreted in the same way. We know that schizophrenics suffer very frequently from associative blockings ("thought-deprivation"). This vanishing of thought usually occurs in the vicinity of the complex. Now if the complex plays the enormous role attributed to it, it is only to be expected that it will very often absorb a great many thoughts and thereby disturb the "fonction du réel"; it creates an associative vacuum in spheres not pertaining to it and thus produces all those perseveration phenomena which the vacuum accounts for.

[187] It is a peculiarity of most ontogenetically acquired automatisms that they are subject to gradual changes. The case histories of patients with tics[44] offer proof of this. Catatonic automatisms are no exception; they, too, change slowly, and the transformation often takes years. I will show what I mean by the following examples.

[188] A catatonic used to sing verbigeratively, for hours on end, a religious song with the refrain "Hallelujah." Then she started verbigerating "Hallelujah" for hours, which gradually degenerated into "Hallo," "Oha," and finally she verbigerated "Ha-ha-ha" accompanied by convulsive laughter.

[189] In the year 1900 a patient used to comb his hair a few hours every day in a stereotyped manner, in order to remove the "plaster that had been rubbed into it during the night." In the following years the comb got further and further away from his head; in 1903 he beat and scratched his chest with it, and now he has reached the inguinal region.

[190] The voices[45] and delusional ideas "degenerate" in a very similar way. The "word salad" arises in the same manner. Sentences that were originally simple become more and more complicated with neologisms, are verbigerated loudly or softly, and gradually become more and more muddled, until finally they turn into an incomprehensible jumble that probably sounds like the "stupid chattering" about which so many schizophrenics complain.

[191] A patient under my observation, recuperating from an acute attack of dementia praecox, began telling herself quietly how she would pack her bags, go from the ward to the asylum gate, then out into the street and to the station, how she gets into the train and reaches her home, where the wedding is solemnized, and so on. This story grew more and more stereotyped, the separate stages got mixed up, sentences were left incomplete, some of them abbreviated into a single catchword; and now, after a year, she uses a catchword only occasionally, all the other words have been replaced by "hm-hm-hm" which she utters in a stereotyped manner in the same tone and rhythm as before when she told her story. In moments of excitement the former sentences reappear. We know from hallucinating patients that the voices in time grow quieter and emptier, but as soon as the excitement returns they regain their content and clarity.

[192] These gradual, stealthy changes can be seen very clearly in obsessions.[46] Janet, too, speaks of the gradual transformation of obsessional processes.[47]

[193] There are, however, stereotypies, or rather stereotyped automatisms, which from the very beginning do not show any psychic content, or at any rate no content that would render them comprehensible even symbolically. I am thinking here of those almost entirely "muscular" manifestations of automatism, such as catalepsy, or certain forms of negativistic muscular resistances. As many investigators have pointed out, we find these markedly catatonic

symptoms in organic disturbances, such as paralysis, brain tumours, etc. Brain physiology and especially the well-known experiments of Goltz have shown that in vertebrates the removal of the cerebrum produces a condition of extreme automatism. Forel's experiments on ants (destruction of the *corpora quadrigemina)* show that automatisms appear when the largest (and most highly differentiated?) portion of the brain tissue is removed. The debrained creature becomes a "reflex-machine," it remains sitting or lying in some favourite position until roused to reflex action by external stimuli. It is no doubt rather a bold analogy to compare certain cases of catatonia to "reflex machines," although the analogy fairly leaps to the eye. But when we penetrate a bit deeper and consider that in this disease a complex has encroached upon almost every area of association and holds it in its grip, that this complex is absolutely inaccessible to psychological stimuli and is isolated from all external influences, the analogy seems to have a rather greater significance. Because of its intensity the complex arrogates to itself the activity of the cerebrum on the widest scale, so that at least a very large number of impulses to other areas disappear. It can then easily be imagined that the complex creates a condition in the brain functionally equivalent to an extensive destruction of the cerebrum. Though this hypothesis cannot be proved, it might nevertheless explain many things that are beyond the reach of psychological analysis.

Summary

[194] Hysteria contains as its innermost core a complex that can never be overcome completely; the psyche is brought to a standstill because it is no longer able to rid itself of this complex. Most of the associations tend in the direction of the complex, and psychic activity consists for the most part merely in elaborating the complex in every possible way. In consequence, the individual (in chronic cases) is bound to become more and more unadapted to the environment. The wish-dreams and wish-deliria of the hysteric are concerned exclusively with the fulfilment of the complex's wishes. Many hysterics succeed, after a time, in regaining their equilibrium by partially overcoming the complex and avoiding new traumata.

[195] In dementia praecox, too, we find one or more complexes which have become permanently fixed and could not, therefore, be overcome. But whereas in persons predisposed to hysteria there is an unmistakable causal connection between the complex and the illness, in dementia praecox it is not at all clear whether the complex caused or precipitated the illness in persons so

predisposed, or whether at the moment of the outbreak of the disease a definite complex was present which then determined the symptoms. The more thoroughly we analyse the symptoms, the more we find that there was, at the onset of the disease, a strong affect from which the initial moodiness developed. In such cases one feels tempted to attribute causal significance to the complex, though with the above-mentioned proviso that besides its psychological effects the complex also produces an unknown quantity, possibly a toxin, which assists the work of destruction. At the same time I am fully aware of the possibility that this X may arise in the first place from non-psychological causes and then simply seize on the existing complex and specifically transform it, so that it may seem as if the complex had a causal effect. Be that as it may, the psychological consequences remain the same: the psyche never rids itself of the complex. An improvement sets in with the atrophy of the complex, but the complex brings with it an extensive destruction of the personality, so that the schizophrenic at best escapes with a psychic mutilation. The alienation from reality, the loss of interest in objective events, are not hard to explain when one considers that schizophrenics are permanently under the spell of an insuperable complex. Anyone whose whole interest is captivated by a complex must be dead to his environment. Janet’s “fonction du réel” consequently ceases to operate. A person with a strong complex thinks in terms of the complex, he dreams with open eyes and no longer adapts psychologically to the environment. What Janet says of the “fonction du réel” in hysteria is true, in a sense, of dementia praecox: “The patient constructs in his imagination little stories that are very coherent and very logical, but when he has to deal with reality he is no longer capable of attention or comprehension.”

[196] The most difficult of these far from simple problems is the hypothetical X, the metabolic toxin (?), and its effects on the psyche. It is uncommonly difficult to describe these effects from the psychological side. If I may be allowed a conjecture, it seems to me that the effect shows itself most clearly in the enormous tendency to automatization and fixation; in other words, in the permanent effects of the complex. Accordingly the hypothetical toxin would have to be thought of as a highly developed substance that attaches itself everywhere to the psychic processes, especially to the feeling-toned processes, reinforcing and automatizing them. Finally, it must be borne in mind that the complex largely absorbs the activity of the cerebrum, so that something like a “debraining” takes place. The consequence of this could be the creation of those forms of automatism which develop principally in the motor system.

[197] This more programmatic than exhaustive survey of the parallels between hysteria and dementia praecox will probably sound hypothetical to many readers unaccustomed to Freud's views. I do not intend it as anything conclusive, but rather as a preliminary sketch that will support and facilitate the discussion of the experimental researches that now follows.

5. ANALYSIS OF A CASE OF PARANOID DEMENTIA AS A PARADIGM

Clinical History

[198] B. St., dressmaker, unmarried, born 1845. The patient was admitted in 1887 and since then has remained permanently in the asylum. She has a severe hereditary taint. Before admission she had, for several years, heard voices that slandered her. For a time she contemplated suicide by drowning. She explained the voices as invisible telephones. They called out to her that she was a woman of doubtful character, that her child had been found in a toilet, that she had stolen a pair of scissors in order to poke out a child's eyes. (According to the anamnesis the patient had led a thoroughly respectable and quiet life.) Now and then she used peculiar expressions, and in general spoke in a somewhat pretentious manner.

[199] The letters she wrote at the time will give some hint of this:

5 July 1887

Dear Superintendent,

With these lines I request you most urgently to discharge me forthwith. My head is *clearer* than ever, as I have already remarked in my last letter. What I have to suffer secretly on account of novelties of all descriptions is unfortunately known to me alone and is too shattering for my health as well as for my mind. Unfortunately they have gone so far as to torture poor victims to death with secret brutalities, for I suffer more than you can imagine and in this manner fully expect my end, which touches me more and more and more sadly. I hope you will act in your capacity as physician and will have no need of any further reflection.

Yours faithfully, etc.

16 August 1887

Dear Sir,

Unfortunately I cannot make it possible for you to appreciate the sad conditions which have obtruded themselves. Once again I call your attention to the simple fact that you should discharge me without further delay, as I suffer all by myself from the novelties and if you were to be convinced of it you would surely discharge me immediately, because I have suffered from the beginning since I came here and am totally at the end of my health; I want an immediate discharge. It gets better immediately I am away from Zurich in another atmosphere where the horrors are no longer in evidence, etc.

[200] The patient produced vivid delusional ideas: she had a fortune of millions, at night her bed was stuck full of needles. In 1888 her speech became more and more incoherent and her delusions unintelligible; for instance she owned the "monopoly," made curious gestures with her hands, a certain "Rubinstein from Petersburg" sent her money by the wagon-load. In 1889 she complained that her spinal marrow was torn out in the night. "Pains in the back are caused by substances going through the walls covered with magnetism." "The monopoly establishes the pains that do not stick in the body and do not fly about in the air." "Extracts are made by an inhalation of chemistry," and "legions perish of death by suffocation." "Station for station must keep their proper governmental positions so that vital departmental questions cannot be chosen to hide behind, things can all be chosen."

[201] In 1890-91 the delusional ideas became more and more absurd. A large but incomprehensible role was played by the word "banknote monopoly." In 1892 the patient became "Queen of the Orphans" and "proprietress of Burghölzli Asylum." "Naples and I must supply the whole world with macaroni." 1894: Stereotyped request for discharge at every visit, but delivered in a totally unemotional manner. 1895: Patient felt paralysed and claimed she had consumption. She is the owner of a "banknote factory seven storeys high with coal-raven-black[1] windows, which means paralysis and starvation." 1896: Patient is "Germania and Helvetia of exclusively sweet butter, but now I have no more butter-content than a fly would leave behind—hm-hm-hm—that is starvation—hm-hm." ("Hm" is a characteristic stereotyped interpolation that still continues.) "I am Noah's Ark, the boat of salvation and respect, Mary Stuart, Empress Alexander." 1897: Patient relates that Dr. D. had recently come out of her mouth, "tiny little Dr. D., the son of the Emperor Barbarossa." 1899: Patient is tormented at night by thousands of snakes.

[202] These notes from the clinical record show quite clearly the nature of the case. At present the patient is, as ever, a diligent worker. Now and then she

gesticulates and whispers during her work, and at the doctor’s visits brings out her questions in a stereotyped manner and unemotional tone of voice: “Have you heard nothing more of the banknotes? I have long since established the monopoly, I am the triple owner of the world,” etc. When she is not actually talking of her delusions her behaviour and speech are quite orderly, though there is an unmistakable affectation such as is often found in elderly spinsters who try to create a substitute for unsatisfied sexuality by the greatest possible perfection of demeanour. She naturally has no insight into her illness, though up to a point finds it comprehensible that her delusions are not understood. There is no imbecility. Her speech is altered only where her delusions are concerned; otherwise she speaks normally, reports on what she has read, and defines ideas in a clear way, provided they do not touch the complex. During tests and analyses she shows great readiness to co-operate and takes visible pains to make herself as intelligible as possible. This behaviour is principally due to the fact that the examination as such is also a complex-stimulant; she is always pressing for interviews, hoping finally to convince us and thus reach the goal of her desires. She is always calm and there is nothing striking in her outward behaviour. While at work she whispers her “power-words” to herself, stereotyped sentences or fragments of sentences with a very strange content, such as: “Yesterday evening I sat in the night train for Nice, had to go through a triumphal arch there—we have established all that already as triple owner of the world—we are also the lilac-new-red sea-wonder,” and so forth. There are masses of such fragments, but they are all stereotyped and are always reproduced in the same form. Motor stereotypies occur but rarely. One stereotypy is the sudden stretching out of the arms, as if the patient wanted to embrace someone.

Simple Word Associations

[203] For two years I have taken simple word associations from the patient at different times, like those described in *Studies in Word Association*. Here are a few samples:

Stimulus-word		***Reaction***	***Reac ti (sec***
1. pupil	2[2]	now you can write Socrates	12.4
2. father	1	yes, mother	7.6

3. table	1	sofa	3.8
4. head	1	yes, irreplaceable	14.8
5. ink	1	nut-water	9.0
6. needle	1	thread	11.4
7. bread	1	butter	3.4
8. lamp	1	electricity, kerosene	6.4
9. tree	1	fruit	6.0
10. mountain	1	valleys	9.4
11. hair	2	hat	6.2

[204] Among these associations there are some that sound quite incomprehensible. The first reaction—*pupil* / *Socrates*—is a really startling reaction for a dressmaker; it looks very affected and immediately suggests a complex-constellation: the tendency to fastidious speech and behaviour. The same applies to reaction 8, *lamp* / *electricity*. Reaction 4, *head* / *yes, irreplaceable*, is unintelligible unless one knows that *irreplaceable* is one of the patient's favourite stereotypies. R. 5, *ink* / *nut-water*, was explained on subsequent questioning: nut-water is dark brown, ink is black. But how does the patient get to *nut-water*? It is again a complex constellation, like *Socrates;* nut-water is something she would like to have. Apart from these peculiarities one is struck by the numerous repetitions of the stimulus-word, the unusually long reaction-times, and the fact that two of the reactions begin with "yes." We regard these signs as symptoms of the complex-constellation, as the intervention of a feeling-toned idea. But it must be remembered that we are dealing here with a dementia-praecox patient who brings out her delusional ideas (which in our view are nothing other than expressions of the complex) with marked lack of affect. If it were a real lack of affect, it would seem at first sight contradictory that the signs of a strong feeling-tone should appear just at the point where one always has the impression of an emotional deficiency. We know from numerous investigations of normal people and hysterics that these signs always signify the emergence of a complex, and we therefore retain this view also in dementia praecox. The inference from this assumption is that most of the above reactions must be constellated by complexes. We have already seen that this is so in R. 1. R. 2, *father* / *yes, mother*, is characterized by the feeling-indicator *yes:*[3] the parents play a considerable role in the delusions of the patient, as we shall see later. R. 3, *table* / *sofa*, looks objective and has therefore a shorter reaction time. On the other hand R. 4, *head* / *yes, irreplaceable,* has a very long reaction-time. The patient refers *head* to herself and predicates this

part of her body as *irreplaceable*, an expression which she otherwise applies to her own person and usually in the stereotyped formula: “I am double polytechnic irreplaceable.” R. 5, *ink* / *nut-water*, is a very far-fetched mediate association: the patient demands, among other things, nut-water. R. 6, *needle* / *thread*, touches her professional complex: she is a dressmaker. R. 7, *bread* / *butter*, is objective. R. 8, *lamp* / *electricity, kerosene*, is also among the things she desires. So is R. 9, *tree* / *fruit*, for she frequently complains about getting too little fruit. Occasionally she dreams of a large gift of fruit. In R. 10, *mountain* / *valleys, mountain* plays a large role in her delusions; she expresses it in the stereotypy: “I created the highest mountain peak, the Finsteraarhorn,” etc. R. 11, *hair* / *hat*, may well be a self-reference, though this has not been clearly confirmed.

[205] We see, then, that the great majority of the associations are constellated by complexes, and this makes the outward signs of feeling-tone immediately understandable. What is not understandable at first sight is the unusually large number of complex-constellations. We find such a profusion in normal people and hysterics only when the complex is extraordinarily intense, that is, when the affect is quite fresh. There is no question of this in our patient: she is perfectly calm, she merely shows the consequences of the affect in her associations, in the one-sided accentuation of the complex without the accompanying emotional excitement. From this we get the clinical impression of “lack of affect.” We have only the husks of the affect, the content is gone. But it may be that the patient has *displaced* the affect and that these husks are merely worn-out expressions of a repressed complex with a reasonable and comprehensible content that cannot be reproduced, so that the affect, too, is buried. Later we shall come back to this possibility.

12. wood	1	cushion	10.2
13. dream	1	reality	3.8
14. copybook	1	satchel	14.4
15. paper	1	official paper	5.0
16. book	1	books	6.8
17. pencil	1	pens	7.6
18. sing	1	singer	5.0
19. ring	1	bond, alliance, or betrothal	16.4
20. tooth	1	denture, teeth	14.8

[206] R. 12, *wood / cushion,* refers to her complaint that there are only hard wooden benches in the asylum; for her own use she wants upholstered furniture. ("I establish upholstered furniture.") R. 13, *dream / reality:* most of her delusional ideas are taken from dreams, and when they are refuted she always insists vehemently on the reality of all the objects of her wishes. R. 15, *paper / official paper,* refers to her delusion that there is an official record of her splendid activities. R. 16, *book / books,* is one of her stereotypies: "I saw the book terribly high above the grounds of the town hall," etc. This stereotypy likewise refers to her extraordinary activities, as we shall see below. The multiple reaction in R. 19, *ring / bond, alliance, or betrothal,* indicates a particularly strong feeling-tone. The erotic complex is obvious here; it plays a great role in the patient's life. R. 20, *tooth / denture, teeth,* is another of her wishes: she would like a new set of false teeth.

21. window	1	door, movable pane, or ventilation	10.6
22. frog	1	I like paralysis best	18.2
23. flower	1	camellia	24.8
24. cherry	1	pear	9.8
25. asylum	1	causation	12.8
26. warder	1	locked in	8.0
27. piano	1	clavier	4.8
28. stove	1	interest-draughts	8.4

[207] R. 21, *window* has a manifold significance in her delusions, one of the most important being what she calls "ventilation": she is tormented every night by faecal odours which she hopes to remove by better ventilation. The very odd reaction to *frog* (R. 22) was explained by the patient as follows: "A person is like that when he watches how a frog jumps. I have always such a paralysis in my legs." "I have a paralysis" or "that is paralysis" is a stereotypy meant to indicate a feeling of paralysis in her legs. One can see from this how very far-fetched are the patient's assimilations to her complex. R. 23, *flower / camellia,* sounds rather affected, but camellias are another adornment of which she dreams. R. 24, *cherry / pear,* belongs to the fruit complex. The remarkable R. 25, *asylum / causation,* was explained by the patient as follows: "Private people cause such asylums. As owner of the world, I established but did not cause this asylum, in spite of the fact that on my admission someone called out that I had." On her admission the voices called out that it was her fault this asylum existed; she denied this, but ever since then she has had the delusional idea that the asylum belongs to her, for as "owner of the world" all big buildings are

“established” or “affirmed” as her property. R. 26, *warder* / *locked in*, is, as the reaction suggests, a perseveration of the preceding complex. R. 28, *stove* / *interest-draughts*, the patient explained thus: “We are the stoves for the State, I am the legator of interest-draughts.” The last sentence is stereotyped; what it means we shall see later. Reactions like *asylum* / *causation* and *stove* / *interest-draughts* are altogether typical of dementia praecox and are not found in any other psychic abnormality.

29. walk	1	that is an extraordinary pleasure for me, when I can go out [She is allowed out once a week.]	[not
30.[4] cook	1	roast	6.8
31. water	1	lemonade	5.0
32. dance	1	Prim, I am Mr. Prim	10.0

Here again a delusional idea is constellated. The patient explained that “Mr. Prim is the foremost dancing teacher in Zurich.” The name and person are unknown to me; it is probably a delusional idea.

33. cat	1	slander	21.8

This far-fetched complex-constellation was explained as follows: “I was once slandered by somebody because I always carried cats in my arms.” It is not clear whether the slander emanated from the voices or from people. The carrying about of cats is a not uncommon symptomatic action in erotic complexes (substitute for child).

34. heart	1	mind	11.2
35. swim	1	I was once almost drowned, drown	[not

This is a complex memory from the beginning of the disease, when there were many thoughts of suicide.

36. Emperor	1	Empress	3.0

“I am Empress Alexander” is one of her stereotypies.

37. moon	1	sun	2.8
38. strike	1	always a proof of brutality	15.8

A reference to occasional attacks by other patients.

39. star	1	Should one say sun, moon, and all the fixed stars?	[not

The complex constellated here is a delusional idea expressed stereo-typically as “I am Forel and Forel’s star.”

40. stroke	1	a word which one cannot write very well: caress	[not

Here again the erotic complex is constellated, as probably also in the previous association. Both reactions came hesitatingly, with a preamble, indicating a feeling of uncertainty (“sentiment d’incomplétude”). This is probably due to the simultaneous stimulation of a strong unconscious complex, which causes the conscious idea to lose its clarity and completeness.

41. splendid	1	annoyance	6.6

Again a far-fetched complex constellation. The patient explained: “One says about unpleasant things: Why, that is splendid!” She finds it particularly annoying that her immense fortune which she has long since “established” is withheld from her so “splendidly.”

42. child	1	parents	6.2
43. sweet	1	I have to experience the bitterness of life	11.0
44. ride	1	I must now be content with driving	8.8

Here the patient again reacts very egocentrically; that is, her complexes use every possible opportunity to assert themselves. “Ride” refers to a stereotypically expressed delusional idea: “I should have been riding horseback since 1866.” This idea refers to her megalomania.

45. friendly	1	yes, friendly, lovely	12.8

Refers to a stereotypically expressed idea of grandeur: “I am royally lovely, so lovely and so pure.”

46. crown	2	villa	17.4

The patient explained: “The Villa S. in T. is my crown. I establish it as my property.” The Villa S. is one of the finest villas in the suburbs of Zurich.

47. rough	1	is mostly brutal	5.6

Assimilation to the brutality complex (R. 38).

48. ill	2	ill is poverty	[not

“Poverty comes from illnesses.”

49. victim	2	cruelty	7.8

As the patient explained, she was the victim of “unheard-of cruelties.”

50. marriage	1	state affair	7.8

Marriage is a state affair in so far as it concerns her marriage, since she is the owner of the world.

51. grandmother	1	is happiness	6.6

“When there is still a grandmother in a family there is happiness.”

52. quarrel	2	always a sign of dangerous	10.4
53. blue	1	sky-blue	3.4
54. sofa	1	cushion	7.2
55. thousand	1	150,000	7.0

This sum corresponds to the “payment” which the patient daily expects.

56. love	1	great abuses	11.4

The patient explained: “People love only themselves.” She meant that nobody bothers about her demands and for this reason she still has to wait for the “payment.”

57. wild	1	Indian	8.2
58. tears	1	mourning	4.4
59. war	1	I never caused any, always misery	6.8
60. faith	1	imperishable	9.0
61. miracle	1	peak	10.0

“It is not conceivable for others that I created the highest mountain peak.”

62. blood	1	ennobled	9.0
63. wreath	1	is festal	7.0

The first association is a clear complex-constellation, the second is a fragment from her fantasies of great festivals.

64. parting	1	generally causes tears	7.2
65. right	1	righteousness	5.8
66. force	1	generally it is cruelty, act of violence	13.0
67. revenge	1	often quite natural in cruelties	14.2
68. little	1	often it is a loss	10.0

“When one has been great and then becomes little, it is a loss.”

69. pray	1	is a ground-pedestal	11.4

“Without religion no one can do anything great.” “Ground-pedestal” is one of her favourite neologisms.

70. unjust	1	is always cruel	8.2
71. world	1	world owner	4.2
72. strange	1	unknown	3.4
73. fruit	1	blessing	15.0
74. false	1	bad	6.6
75. helmet	3	hero, heroic deed	11.4

The patient compares herself and her deeds to the greatest the world has ever known. She therefore uses “helmet” to express the complex.

76. dress	1	taste	3.4

She is a dressmaker and always boasts of her excellent taste.

77. gentle	1	tact	6.0

Patient explains: “If you pass through a bedroom you should walk gently, so as not to wake the others.” This is an obvious constellation from asylum life, with the implication that she has the necessary tact.

78. misery	1	crutches	7.8

A mediate association to “paralysed.” Patient feels herself “paralysed.”

79. hay	1	harvest	4.8
80. clean	1	good conditions	24.4

“Cleanliness creates good conditions,” a general expression of implied self-praise.

81. raspberries	1	jam, syrup	3.8

One of the things she wants.

82. head	1	wisdom	22.0

Refers to the complex of her extraordinary intelligence.

[208] I do not want to pile up the examples, for those I have given contain all the essentials. The most striking thing is the enormous number of perfectly clear complex-constellations. With a few exceptions all the associations are thinly veiled expressions of complexes. Because the complexes are conspicuously in the foreground everywhere, the experiment is disturbed throughout. The extraordinarily long reaction-times could be explained in part by the continual interference of complexes, which is seldom seen in normal people or even in hysterics. From this we can conclude that the psychic activity of the patient is completely taken up by the complex: she is under the sway of the complex, she speaks, acts, and dreams nothing but what the complex suggests to her. There seems to be a certain intellectual weakness which expresses itself in a *tendency*

to give definitions, though unlike the same tendency in imbeciles it does not strive for generalization[5] but defines the content of the stimulus-words in terms of the complex. Characteristic is the extraordinarily stilted and affected manner of expression, sometimes verging on the incomprehensible. The clumsy and peculiar-sounding definitions of imbeciles occur at the intellectually difficult places, as might be expected, but here the affected definitions occur at unexpected places which happen to hit the complex. In normal people and hysterics we find striking or linguistically odd reactions always at the critical places, and especially words from foreign languages. These correspond here to the neologisms, which are nothing but peculiarly forceful and ponderous expressions of thought-complexes. We can also understand why the patient describes her neologisms as “power-words.” Wherever they appear they hint at the whole system hidden behind them, just as technical terms do in normal speech.

[209] We see, then, that the complex is stimulated even by the most far-fetched words; it assimilates everything that comes into its orbit.

[210] In normal people and in hysterics we find roughly the same situation when there are very strong complexes and the affect is still fresh. The patient therefore reacts to the experiment like a person with a fresh affect. In reality this is naturally not the case, even though the influence on the associations is such as occurs only when the affect is fresh. By far the greatest number of the reactions are constellated in the most obvious way by subjective complexes. We can explain this fact on the hypothesis put forward in the preceding chapters, that dementia praecox has an abnormally strong affective content which becomes stabilized with the onset of the disease. If this hypothesis is correct and holds true for all forms of dementia praecox, we may expect as a characteristic feature of the associations an abnormally strong predominance of complexes. So far as my experience goes, this is true in all cases. In this respect, too, the similarity to hysteria is very great. The principal complexes which the experiment has touched on are as follows:

[211] *The complex of personal grandeur*. This constellates most of the associations and expresses itself above all in the affectation, whose sole purpose is to emphasize the value of the personality. To that extent it is a normal and familiar aid to self-complacency. Here it is exaggerated in accordance with the patient’s morbidly intensified self-esteem. Because the underlying affect apparently never weakens, it lasts for years and becomes a mannerism that contrasts glaringly with reality. We see the same thing in normal people who are

excessively vain and keep up their supercilious airs even when the real situation in no way warrants it. Hand in hand with the exaggerated affectation go exaggerated ideas of grandeur which, because of their contrast with reality and the affected, barely intelligible way they are expressed, have something grotesque about them. We find this phenomenon in normal people whose self-esteem is at odds with their intelligence and outward situation. In the patient it is primarily a question of exaggeration and the correspondingly strong affect it indicates. What exceeds the normal mechanism is the barely intelligible and unadapted manner of expression, which suggests an impairment of the underlying concepts. The complex of personal grandeur expresses itself also in the patient's unsuitable demands and wishes.

Contrasting with the complex of grandeur is the *complex of injury*, which likewise appears with great clarity. In this disease it is the usual compensation of grandeur. Here again the expression is exaggerated, difficult to understand, and grotesque.

[213] There are also indications of an *erotic complex*. Though largely disguised by the other two, it may well be the most important; in women this is even to be expected. Significantly, perhaps, it remains in the background, the other complexes being merely its displacements. We shall come back to this later.

[214] A person of great sensitivity and exaggerated self-esteem will receive many hard knocks in the world, and these may easily lay the foundation for the complex of grandeur and the complex of injury. Accordingly the specific feature is hardly to be found in these mechanisms. We must seek it, rather, in the symptoms that are furthest from the normal; that is, in those elements that are *unintelligible*. These include, above all, the neologisms. I therefore subjected the new speech-formations of the patient to a special study, hoping in this way to find the clue to the essential factor.

Continuous Associations

[215] At first I tried to get the patient to tell me outright what she meant by her neologisms. This attempt was a total failure, as she immediately came out with a string of fresh neologisms resembling a word salad. She spoke in a matter-of-fact tone, as if she were perfectly clear about the meaning of her words and thought that what she was saying constituted an explanation. I realized that direct questioning would lead to nothing, just as in hysteria when one asks directly about the origin of the symptoms. I therefore employed a device that

can also be used with profit in hysteria: I got the patient to tell me all her associations to a stimulus-word. In this way the idea can be associated in all directions and its various connections discovered. As stimulus-words I chose the neologisms, of which the patient had dozens. As she spoke very slowly with reference to her delusional ideas and was continually hindered by "thought-deprivations" (inhibitions caused by the complex), there was plenty of time for a literal transcript. I reproduce the tests verbatim, omitting only the repetitions.

A. WISH-FULFILMENT

[216] (1) *Socrates:* "Pupil—books—wisdom—modesty—no words to express this wisdom—is the highest ground-pedestal—his teachings—had to die because of wicked men—falsely accused—sublimest sublimity—self-satisfied—that is all Socrates—the fine learned world—never cut a thread—I was the best dressmaker, never left a bit of cloth on the floor—fine world of art—fine professorship—is doubloon—25 francs—that is the highest—prison—slandered by wicked men—unreason—cruelty-depravity—brutality."

[217] The associations did not come smoothly but were constantly inhibited by "thought-deprivation," which the patient described as an invisible force that always took away just what she wanted to say. This occurred whenever she wanted to explain something crucial. The crucial thing was the complex. As we can see from the above analysis, the essential factor appeared only after having been preceded by a number of obscure analogies.[6] The object of the test was, as the patient knew, to explain the neologisms. So if it took her such a long time to reproduce the important phrase "never cut a thread," then her powers of conception must suffer from a peculiar disturbance which can best be described as a lack of ability to discriminate between important and unimportant material. The explanation of her stereotypy "I am Socrates" or "I am Socratic" is that she is the "best dressmaker" who "never cut a thread" and "never left a bit of cloth on the floor." She is an "artist," a "professor" in her line. She is martyred, she is not recognized as the owner of the world, she is considered ill, which is a "slander." She is "wise" and "modest," she has achieved "the highest." All these things are analogies of the life and death of Socrates. She therefore wishes to say: "I am like Socrates, and I suffer like him." With a certain poetic licence, such as appears also in moments of strong affect, she says outright: "I am Socrates." The really pathological element is that she is so identified with Socrates that she can no longer get away from him; she takes the identification

at its face value and regards the metonymy as so real that she expects everybody to understand it.

[218] Here is a clear instance of deficient discrimination between two ideas: every normal person can distinguish between an assumed role or metaphorical name and his real personality, even though a lively fantasy or intense feeling-tone may attach itself for a time to such a dream- or wish-formation. The correction does finally come with a reversal of feeling, and with it a re-adaptation to reality. In the unconscious the process is somewhat different. We saw, for instance, how dreams change metaphors into a reality which is substituted for the person of the dreamer, or how an unconscious complex immediately "condenses" a distant analogy and a person, and thereby attains the necessary intensity to disturb the conscious process ("A pine-tree stands alone," etc.). If at that moment the unconscious complex, in a short twilight state, had attained innervation in speech, the patient would have said: "I am the pine-tree." As we have shown in the preceding chapters, the necessary premise for these condensations is the indistinctness of ideas, such as normally exists in the unconscious. This would also explain the condensations in our case. As soon as the patient thinks in terms of the complex she no longer thinks with normal energy or distinctness, but indistinctly, dreamily, as normally happens in the unconscious or in dreams. As soon as her associations enter the realm of the complex the hierarchy of the directing idea ceases, and the stream of thought moves forward in dreamlike analogies which, in the self-evident way of dreams, are equated with reality. The complex functions automatically in accordance with the law of analogy; it is completely freed from the control of the ego-complex, and for this reason the ego-complex can no longer direct the associations; on the contrary, it is subordinated to the complex and continually disturbed by defective reproductions (thought-deprivation) and compulsive associations (pathological ideas). The same process of obscuration that takes place with regard to ideas also occurs in speech: it gradually becomes indistinct, similar expressions are substituted for one another, there are clang-displacements and indirect (linguistic) associations. Thus it does not matter to the patient whether she says "artist" or "fine world of art," "professorship" instead of "professor," "fine learned world" instead of "skilled dressmaker." These ideas take one another's place with the same facility as do the personality of the patient and Socrates. Characteristically, the accent does not fall on the simple but on the unusual, for this is in keeping with her hankering for distinction.

[219] (2) *Double polytechnic* (stereotypy: “I am double polytechnic irreplaceable”): “That is the highest, all-highest—the highest of dressmaking—the highest achievement—the highest intelligence—the highest achievement in the culinary art—the highest achievement in all spheres—the double polytechnic is irreplaceable—the universal with 20,000 francs—never cut a thread—fine world of art—not apply a thread of trimming where it is not seen—plum-tart with corn-meal crust—it is of the greatest importance—finest professorship—is a doubloon—25 francs—Schneckenmuseum clothing is the highest—salon and bedroom—should live there as double polytechnic.”

[220] The content of “double polytechnic” is very like that of “Socrates,” only here the “arts” are even more emphasized. Besides “dressmaking” we have the “culinary art” with her specialty—“plum-tart with corn-meal crust.” The art of dressmaking reappears in the same stereotyped groups of associations as before. It is quite clear that “double polytechnic” is simply another metonymy for the acme of art and wisdom. A further specification lies in “should live there,” namely in the Polytechnic Institute, as the patient later told me. It is no contradiction for her consciousness, any more than it would be for a dream, that she lives in the Polytechnic as a “double polytechnic.” It was also quite impossible to make her realize the absurdity of this; she simply answered with one of her stereotypies. The Polytechnic in Zurich is a stately building and therefore “belongs to her.” “Double” is an obscure epithet which is perhaps echoed in “doubloon”; this may be a reference to the reward she expects for her “highest achievement.” “Double” may be meant as an intensification, but it may have another meaning of which we shall speak later. If “double polytechnic” is the “highest,” the epithet “irreplaceable” then becomes clear.

[221] (3) *Professorship* (stereotypy: “I am the finest professorship”). “That is again the highest achievement—double—25 francs—I am double polytechnic irreplaceable—professorship includes the fine learned world—the finest world of art—I am these titles too—I am Schneckenmuseum clothing, that comes from me—never cut a thread—choose the best patterns that show up well—the finest learned world includes that—choose the best patterns that show up well and waste little cloth—I did that—that’s my line—the fine world of art is to apply trimming only where it is seen—plum-tart with corn-meal crust—the finest professorship is double—25 francs—it doesn’t go any further—no one can get any further than 25 francs—Schneckenmuseum clothing is the highest clothing—the others always want to connect the learned world with astronomy and all that.”

[222] The content of “professorship” agrees with that of the two concepts analysed above. “Professorship” is simply another symbolic designation for the megalomaniac idea that the patient is the best dressmaker. “Doubloon” is here replaced by the clang-similarity “double”; for the patient they are obviously equivalent. A doubloon corresponds to 25 francs and it is evident that this means the highest daily wage she can earn by her work. The expression “Schneckenmuseum clothing” is a symbolic designation for the product of her art, which she considers the “highest clothing.” It can be explained as follows: the Museum is the haunt of intellectual circles in Zurich, the Haus zur Schnecke stands near the Museum and is a prominent guild. These two ideas have been fused together in the singular concept “Schneckenmuseum clothing,” which, as the patient says, means the “highest clothing.” Her speech usage is interesting. She does not say “I make” but “I *am* the Schneckenmuseum clothing, that comes from me.” She “condenses” or identifies herself with this object too, at least in so far as she treats “I am” and “that comes from me” as equivalent. “I am” seems to be an intensified form of “I have” or “I make.”

[223] The three concepts so far analysed are technical terms which characterize a wealth of ideas and relationships in what seems to the patient a very pregnant way. When she whispers to herself she simply repeats these terms and nods affirmatively, but the explanatory material is lacking. The origin of the terms is not known; some of them, according to the patient, come from dreams. Probably they arose spontaneously on some occasion and impressed the patient on account of their strangeness, in the same way that philosophers who think in nebulous concepts like playing with obscure words.
